During "color expansion" the individual bits of monochrome source or pattern data that correspond to individual pixels are converted into 1, 2, or 4 bytes (whichever is appropriate for the color depth to which the BLT engine has been set). If a given bit of monochrome source or pattern data carries a value of 1, then the byte(s) of color data resulting from the conversion process are set to carry the value of a specified foreground color. If a given bit of monochrome source or pattern data carries a value of 0, the resulting byte(s) are set to the value of a specified background color or not written if transparency is selected.

The BLT engine is set to a default configuration color depth of 8, 16, or 32 bits per pixel through BLT command packets. Whether the source and pattern data are color or monochrome must be specified using command packets. Foreground and background colors for the color expansion of both monochrome source and pattern data are also specified through the command packets. The source foreground and background colors used in the color expansion of monochrome source data are specified independently of those used for the color expansion of monochrome pattern data.

Graphics Data Size Limitations

The BLT engine is capable of transferring very large quantities of graphics data. Any graphics data read from and written to the destination is permitted to represent a number of pixels that occupies up to 65,536 scan lines and up to 32,768 bytes per scan line at the destination. The maximum number of pixels that may be represented per scan line's worth of graphics data depends on the color depth.

Any source data used as an input must represent the same number of pixels as is represented by any data read from or written to the destination, and it must be organized so as to occupy the same number of scan lines and pixels per scan line.

The actual number of scan lines and bytes per scan line required to accommodate data read from or written to the destination are set in the destination width & height registers or using X and Y coordinates within the command packets. These two values are essential in the programming of the BLT engine, because the engine uses these two values to determine when a given BLT operation has been completed.

Bit-Wise Operations

The BLT engine can perform any one of 256 possible bit-wise operations using various combinations of the three previously described blocks of graphics data that the BLT engine can receive as input.

The choice of bit-wise operation selects which of the three inputs will be used, as well as the particular logical operation to be performed on corresponding bits from each of the selected inputs. The BLT engine automatically foregoes reading any form of graphics data that has not been specified as an input by the choice of bit-wise operation. An 8-bit code written to the raster operation field of the command packets chooses the bit-wise operation. The following table lists the available bit-wise operations and their corresponding 8-bit codes.

Bit-Wise Operations and 8-Bit Codes (00-3F)

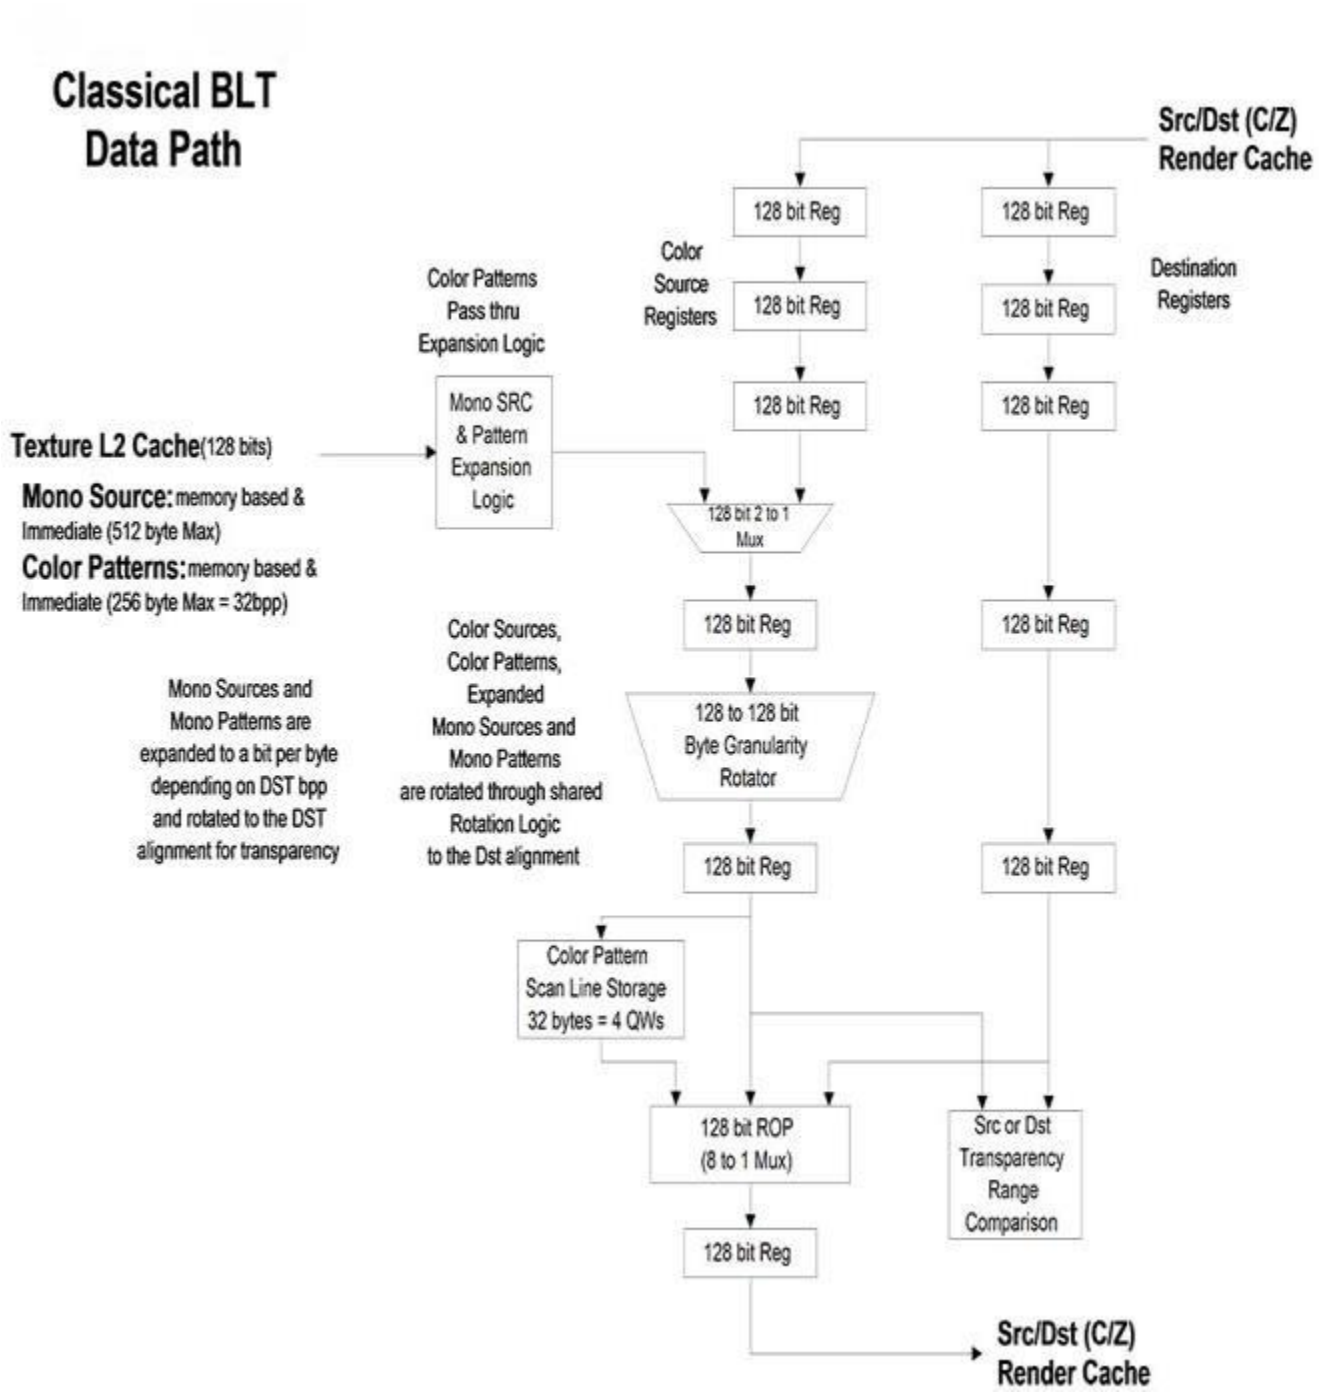
Per-Pixel Write-Masking Operations

The BLT engine is able to perform per-pixel write-masking with various data sources used as pixel masks to constrain which pixels at the destination are to be written to by the BLT engine. As shown in the figure below, either monochrome source or monochrome pattern data may be used as pixel masks. Color pattern data cannot be used. Another available pixel mask is derived by comparing a particular color range per color channel to either the color already specified for a given pixel at the destination or source.



Block Diagram and Data Paths of the BLT Engine

The command packets can specify the monochrome source or the monochrome pattern data as a pixel mask. When this feature is used, the bits that carry a value of 0 cause the bytes of the corresponding pixel at the destination to not be written to by the BLT engine, thereby preserving whatever data was originally carried within those bytes. This feature can be used in writing characters to the display, while also preserving the pre-existing backgrounds behind those characters. When both operands are in the transparent mode, the logical AND of the 2 operands are used for the write enables per pixel.

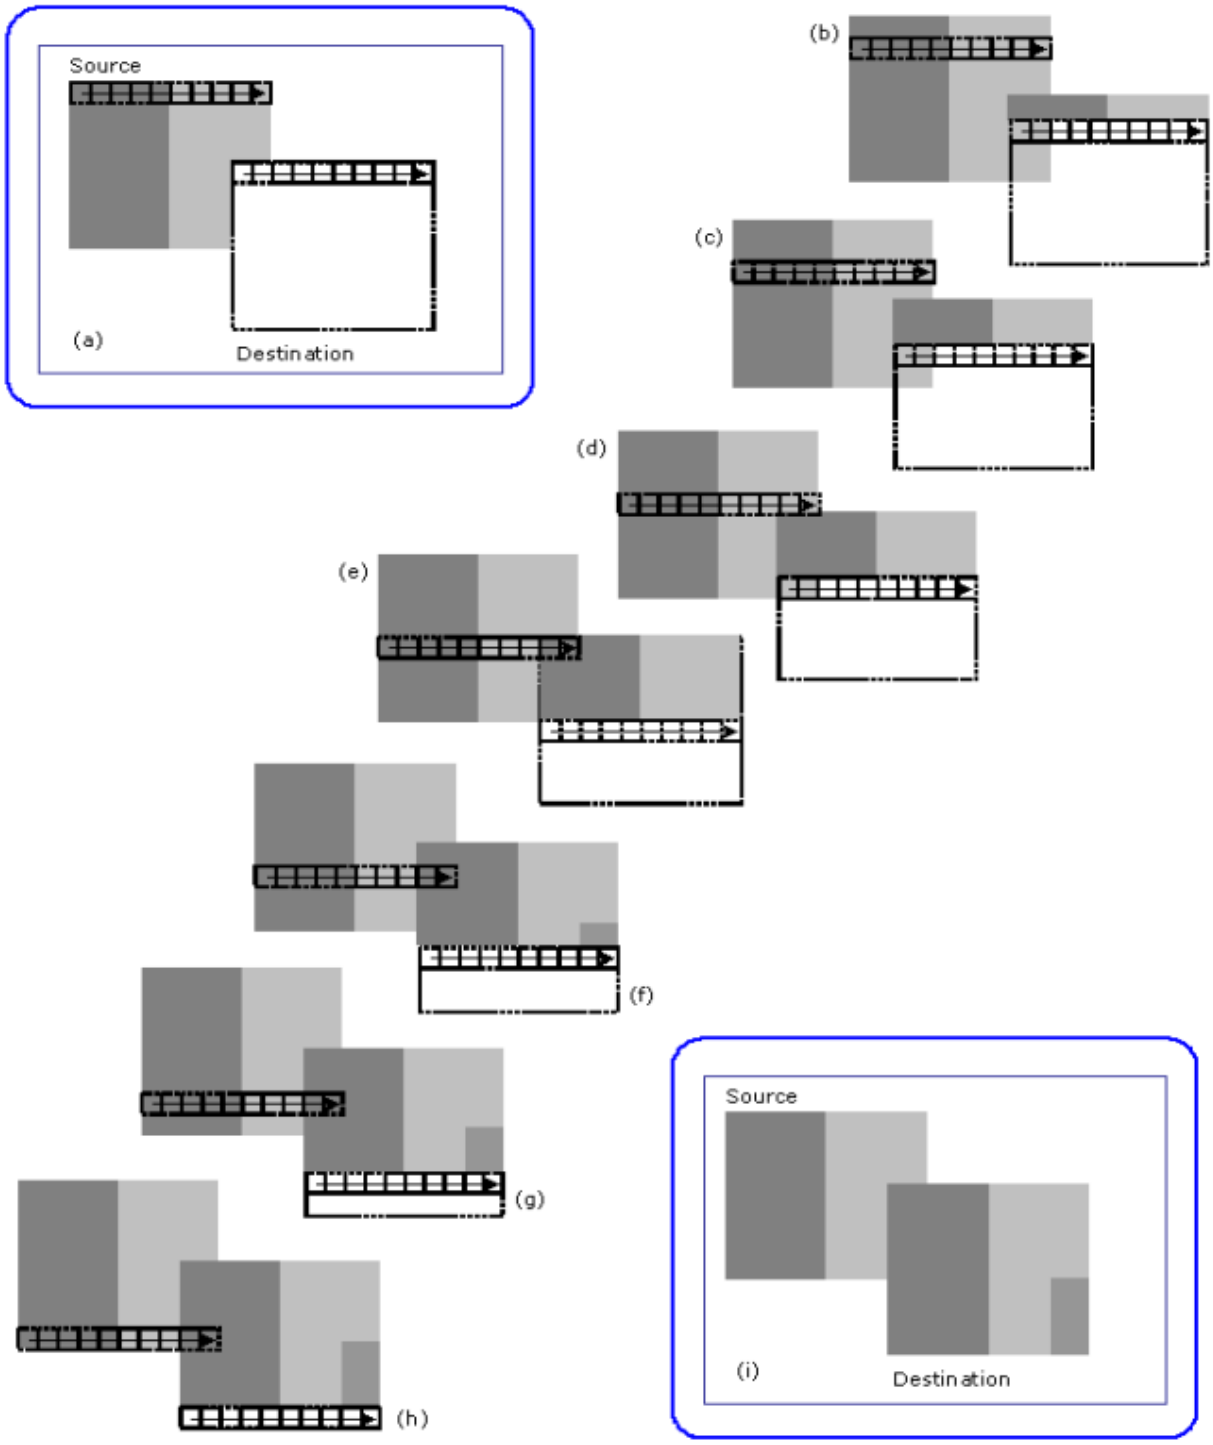
The 3-bit field, destination transparency mode, within the command packets can select per-pixel write-masking with a mask based on the results of color comparisons. The monochrome source background and foreground are range compared with either the bytes for the pixels at the destination or the source operand. This operation is described in the BLT command packet and register descriptions.

When the Source and Destination Locations Overlap

It is possible to have BLT operations in which the locations of the source and destination data overlap. This frequently occurs in BLT operations where a user is shifting the position of a graphical item on the display by only a few pixels. In these situations, the BLT engine must be programmed so that destination data is not written into destination locations that overlap with source locations before the source data at those locations has been read. Otherwise, the source data will become corrupted. The XY commands determine whether there is an overlap and perform the accesses in the proper direction to avoid data corruption.

The following figure shows how the source data can be corrupted when a rectangular block is copied from a source location to an overlapping destination location. The BLT engine typically reads from the source location and writes to the destination location starting with the left-most pixel in the top-most line of both, as shown in step (a). As shown in step (b), corruption of the source data has already started with the copying of the top-most line in step (a) -- part of the source that originally contained lighter-colored pixels has now been overwritten with darker-colored pixels. More source data corruption occurs as steps (b) through (d) are performed. At step (e), another line of the source data is read, but the two right-most pixels of this line are in the region where the source and destination locations overlap, and where the source has already been overwritten as a result of the copying of the top-most line in step (a). Starting in step (f), darker-colored pixels can be seen in the destination where lighter-colored pixels should be. This errant effect occurs repeatedly throughout the remaining steps in this BLT operation. As more lines are copied from the source location to the destination location, it becomes clear that the end result is not what was originally intended.

Source Corruption in BLT with Overlapping Source and Destination Locations

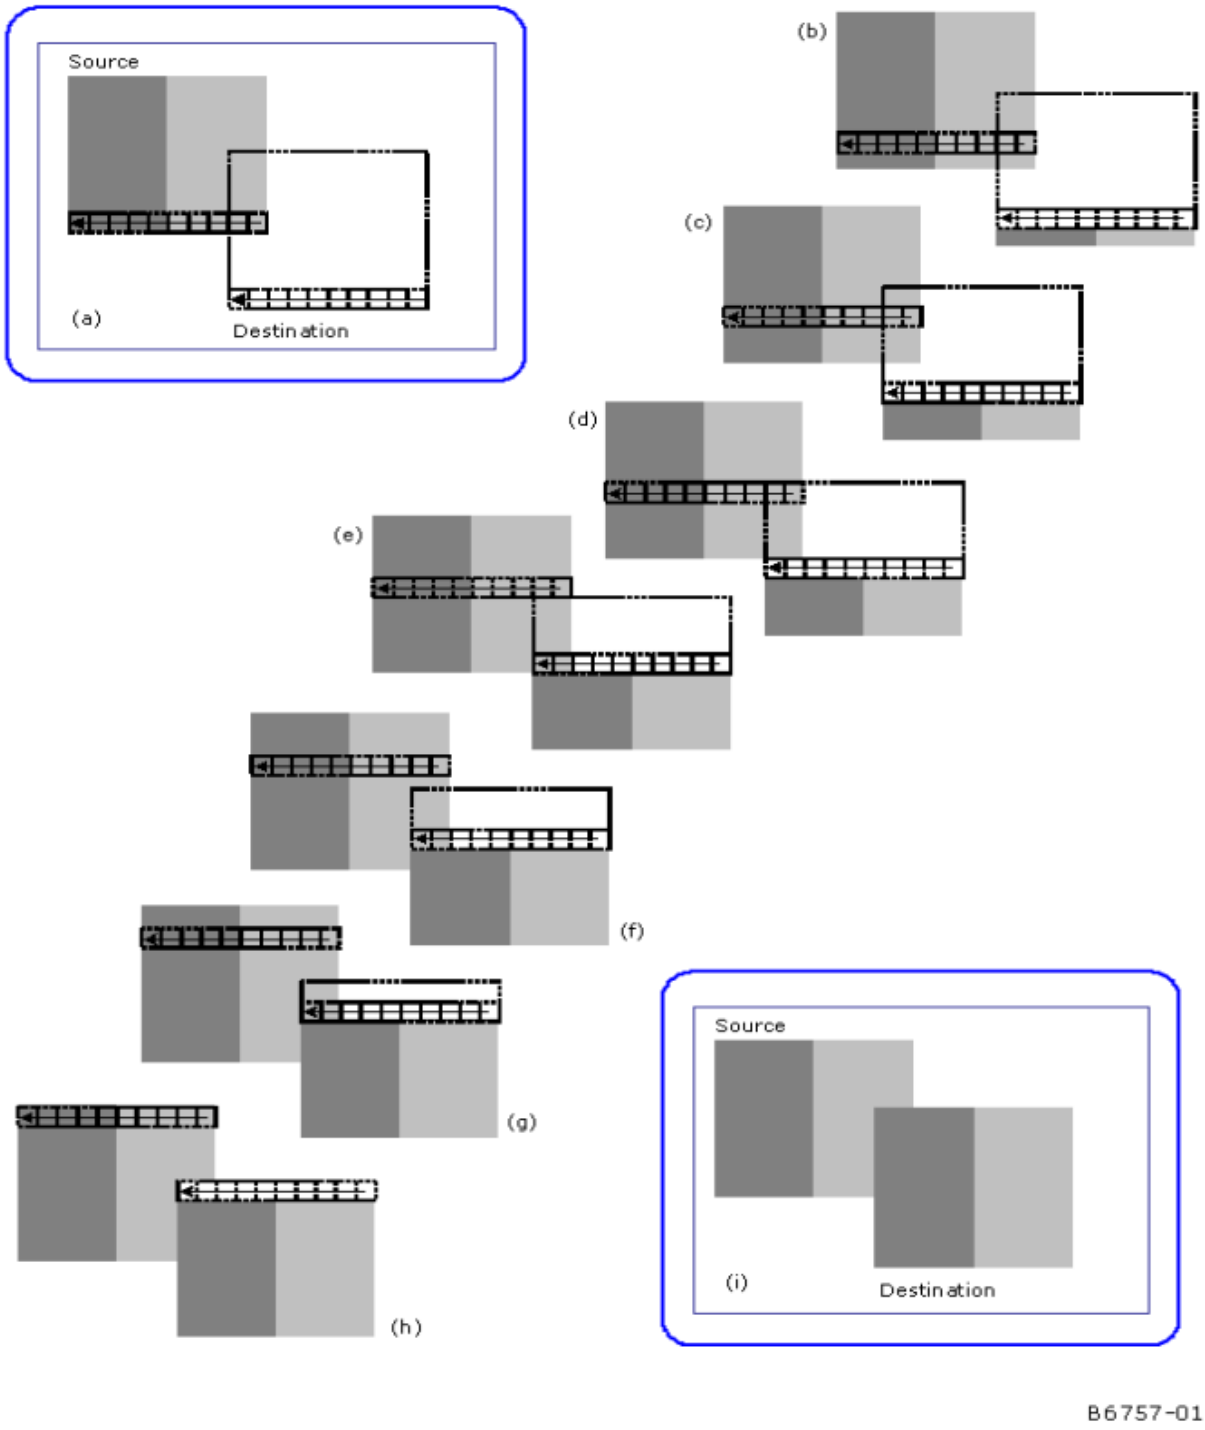


The BLT engine can alter the order in which source data is read and destination data is written when necessary to avoid source data corruption problems when the source and destination locations overlap. The command packets provide the ability to change the point at which the BLT engine begins reading

and writing data from the upper left-hand corner (the usual starting point) to one of the other three corners. The BLT engine may be set to read data from the source and write it to the destination starting at any of the four corners of the panel.

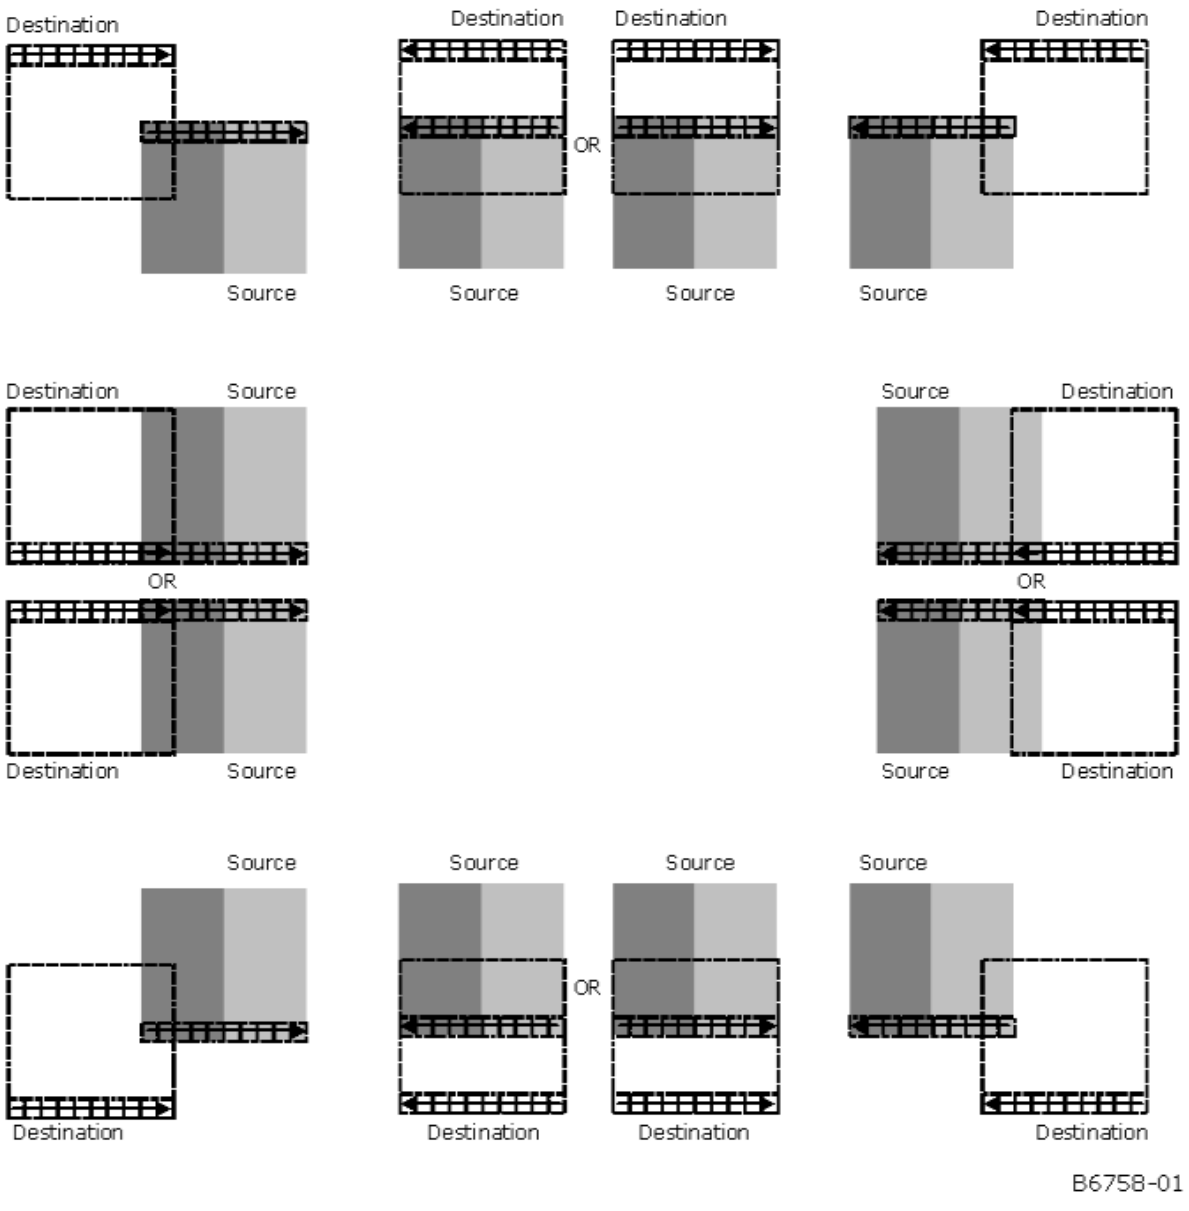
The XY command packets perform the necessary comparisons and start at the proper corner of each operand which avoids data corruption.

Correctly Performed BLT with Overlapping Source and Destination Locations



The following figure illustrates how this feature of the BLT engine can be used to perform the same BLT operation as was illustrated in the figure above, while avoiding the corruption of source data. As shown in the figure below, the BLT engine reads the source data and writes the data to the destination starting with the right-most pixel of the bottom-most line. By doing this, no pixel existing where the source and destination locations overlap will ever be written to before it is read from by the BLT engine. By the time the BLT operation has reached step (e) where two pixels existing where the source and destination locations overlap are about to be over written, the source data for those two pixels has already been read.

Suggested Starting Points for Possible Source and Destination Overlap Situations



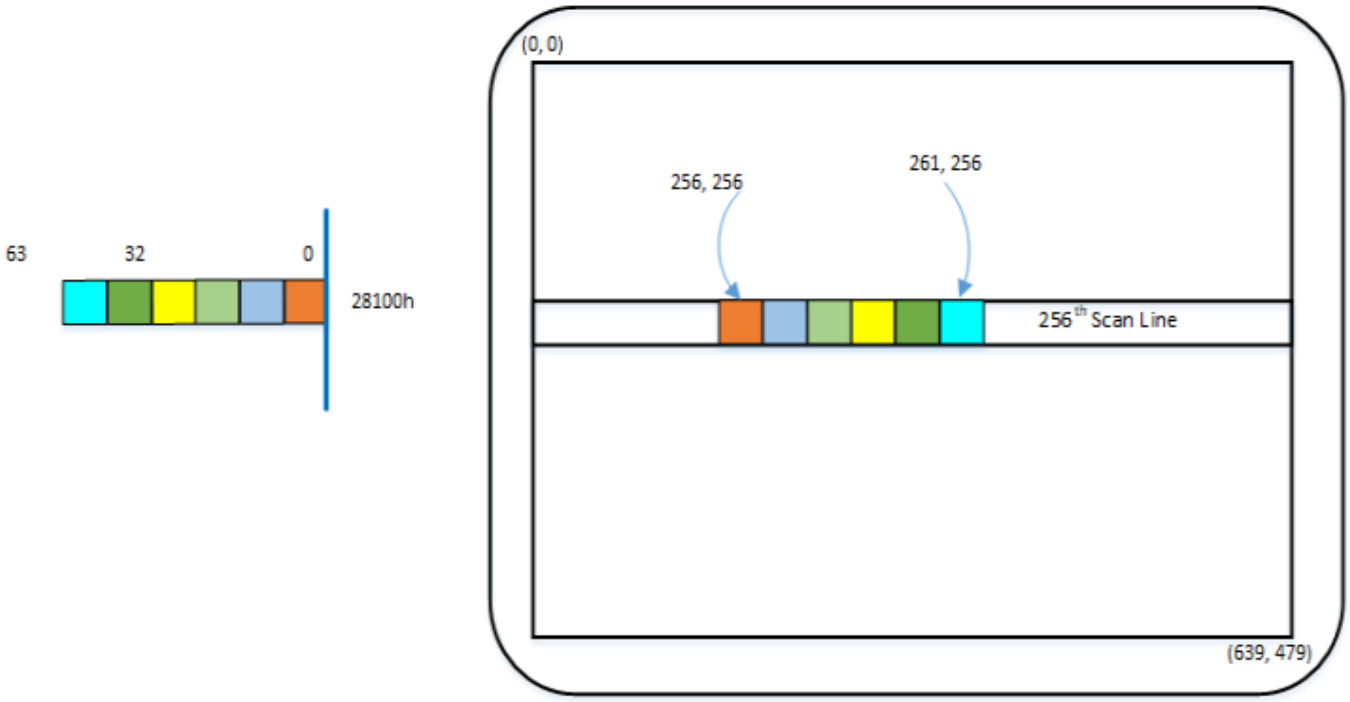
The figure above shows the recommended lines and pixels to be used as starting points in each of 8 possible ways in which the source and destination locations may overlap. In general, the starting point should be within the area in which the source and destination overlap.

Basic Graphics Data Considerations

Contiguous vs. Discontinuous Graphics Data

Graphics data stored in memory, particularly in the frame buffer of a graphics system, has organizational characteristics that often distinguish it from other varieties of data. The main distinctive feature is the tendency for graphics data to be organized in a discontinuous block of graphics data made up of multiple sub-blocks of bytes, instead of a single contiguous block of bytes.

Representation of On-Screen Single 6-Pixel Line in the Frame Buffer

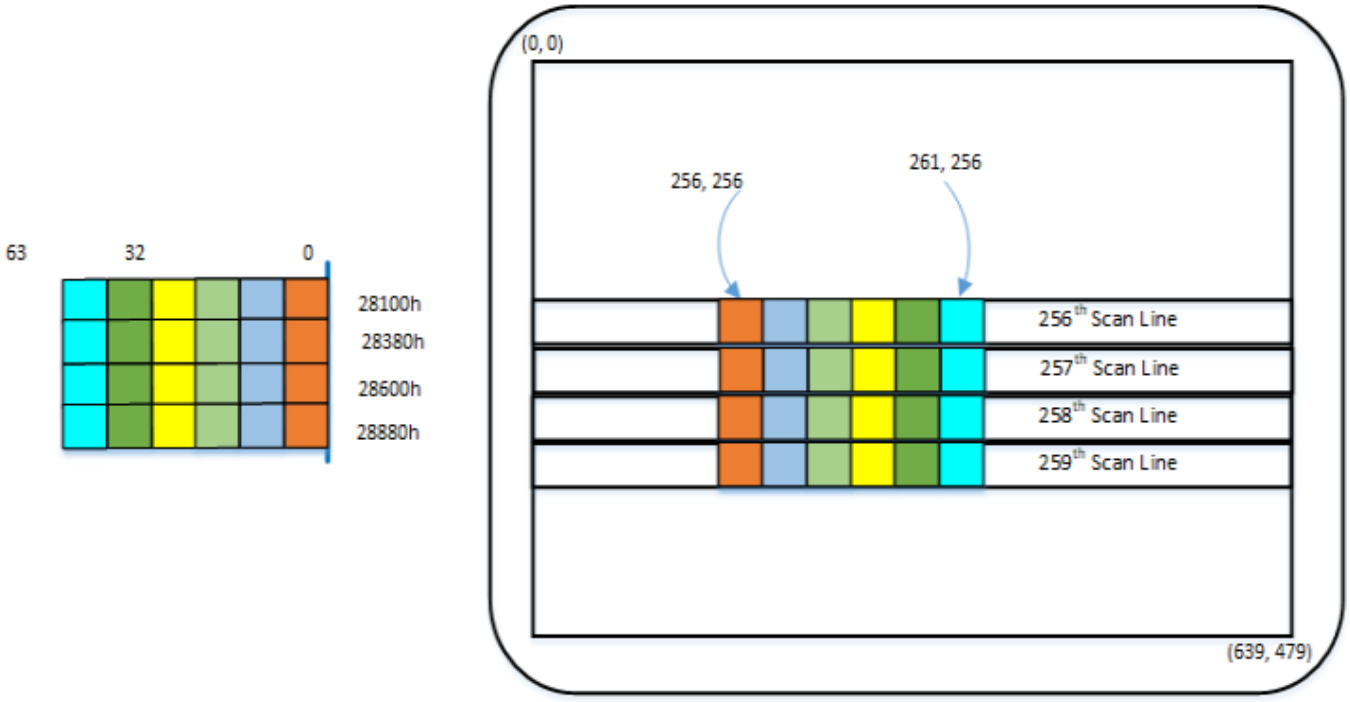


The figure above shows an example of contiguous graphics data -- a horizontal line made up of six adjacent pixels within a single scan line on a display with a resolution of 640x480. Presuming that the graphics system driving this display has been set to 8 bits per pixel and that the frame buffer's starting address of 0h corresponds to the upper left-most pixel of this display, then the six pixels that make this horizontal line starting at coordinates (256, 256) occupies the six bytes starting at frame buffer address 28100h, and ending at address 28105h.

In this case, there is only one scan line's worth of graphics data in this single horizontal line, so the block of graphics data for all six of these pixels exists as a single, contiguous block comprised of only these six bytes. The starting address and the number of bytes are the only pieces of information that a BLT engine would require to read this block of data.

The simplicity of the above example of a single horizontal line contrasts sharply to the example of discontinuous graphics data depicted in the figure below. The simple six-pixel line of the figure above is now accompanied by three more six-pixel lines placed on subsequent scan lines, resulting in the 6x4 block of pixels shown.

Representation of On-Screen 6x4 Array of Pixels in the Frame Buffer



Since there are other pixels on each of the scan lines on which this 6x4 block exists that are not part of this 6x4 block, what appears to be a single 6x4 block of pixels on the display must be represented by a discontinuous block of graphics data made up of 4 separate sub-blocks of six bytes apiece in the frame buffer at addresses 28100h, 28380h, 28600h, and 28880h. This situation makes the task of reading what appears to be a simple 6x4 block of pixels more complex. However, there are two characteristics of this 6x4 block of pixels that help simplify the task of specifying the locations of all 24 bytes of this discontinuous block of graphics data: all four of the sub-blocks are of the same length, and the four sub-blocks are separated from each other at equal intervals.

The BLT engine is designed to make use of these characteristics of graphics data to simplify the programming required to handle discontinuous blocks of graphics data. For such a situation, the BLT engine requires only four pieces of information: the starting address of the first sub-block, the length of a sub-block, the offset (in bytes), pitch, of the starting address of each subsequent sub-block, and the quantity of sub-blocks.

Source Data

The source data may exist in the frame buffer or elsewhere in the graphics aperture where the BLT engine may read it directly, or it may be provided to the BLT engine by the host CPU through the command packets. The block of source graphics data may be either contiguous or discontinuous, and may be either in color (with a color depth that matches that to which the BLT engine has been set) or monochrome.

The source select bit in the command packets specifies whether the source data exists in the frame buffer or is provided through the command packets. Monochrome source data is always specified as being supplied through an immediate command packet.

If the color source data resides within the frame buffer or elsewhere in the graphics aperture, then the Source Address Register, specified in the command packets is used to specify the address of the source.

In cases where the host CPU provides the source data, it does so by writing the source data to ring buffer directly after the BLT command that requires the data or uses an IMMEDIATE_INDIRECT_BLT command packet which has a size and pointer to the operand in Graphics aperture.

The block of bytes sent by the host CPU through the command packets must be quadword-aligned and the source data contained within the block of bytes must also be aligned.

To accommodate discontinuous source data, the source and destination pitch registers can be used to specify the offset in bytes from the beginning of one scan line's worth source data to the next. Otherwise, if the source data is contiguous, then an offset equal to the length of a scan line's worth of source data should be specified.

Monochrome Source Data

The opcode of the command packet specifies whether the source data is color or monochrome. Since monochrome graphics data only uses one bit per pixel, each byte of monochrome source data typically carries data for 8 pixels which hinders the use of byte-oriented parameters when specifying the location and size of valid source data. Some additional parameters must be specified to ensure the proper reading and use of monochrome source data by the BLT engine. The BLT engine also provides additional options for the manipulation of monochrome source data versus color source data.

The various bit-wise logical operations and per-pixel write-masking operations were designed to work with color data. In order to use monochrome data, the BLT engine converts it into color through a process called color expansion, which takes place as a BLT operation is performed. In color expansion the single bits of monochrome source data are converted into one, two, or four bytes (depending on the color depth) of color data that are set to carry value corresponding to either the foreground or background color that have been specified for use in this conversion process. If a given bit of monochrome source data carries a value of 1, then the byte(s) of color data resulting from the conversion process will be set to carry the value of the foreground color. If a given bit of monochrome source data carries a value of 0, then the resulting byte(s) will be set to the value of the background color. The foreground and background colors used in the color expansion of monochrome source data can be set in the source expansion foreground color register and the source expansion background color register.

The BLT Engine requires that the bit alignment of each scan line's worth of monochrome source data be specified. Each scan line's worth of monochrome source data is word aligned but can actually start on any bit boundary of the first byte. Monochrome text is special cased, and it is bit or byte packed, where in bit packed there are no invalid pixels (bits) between scan lines. There is a 3 bit field which indicates the starting pixel position within the first byte for each scan line, Mono Source Start.

Note that the Monosource surface start Base Address, should always be Cache Line (64byte) aligned.

The BLT engine also provides various clipping options for use with specific BLT commands (BLT_TEXT) with a monochrome source. Clipping is supported through: Clip rectangle Y addresses or coordinates and X coordinates along with scan line starting and ending addresses (with Y addresses) along with X starting and ending coordinates.

The maximum immediate source size is 128 bytes.

Pattern Data

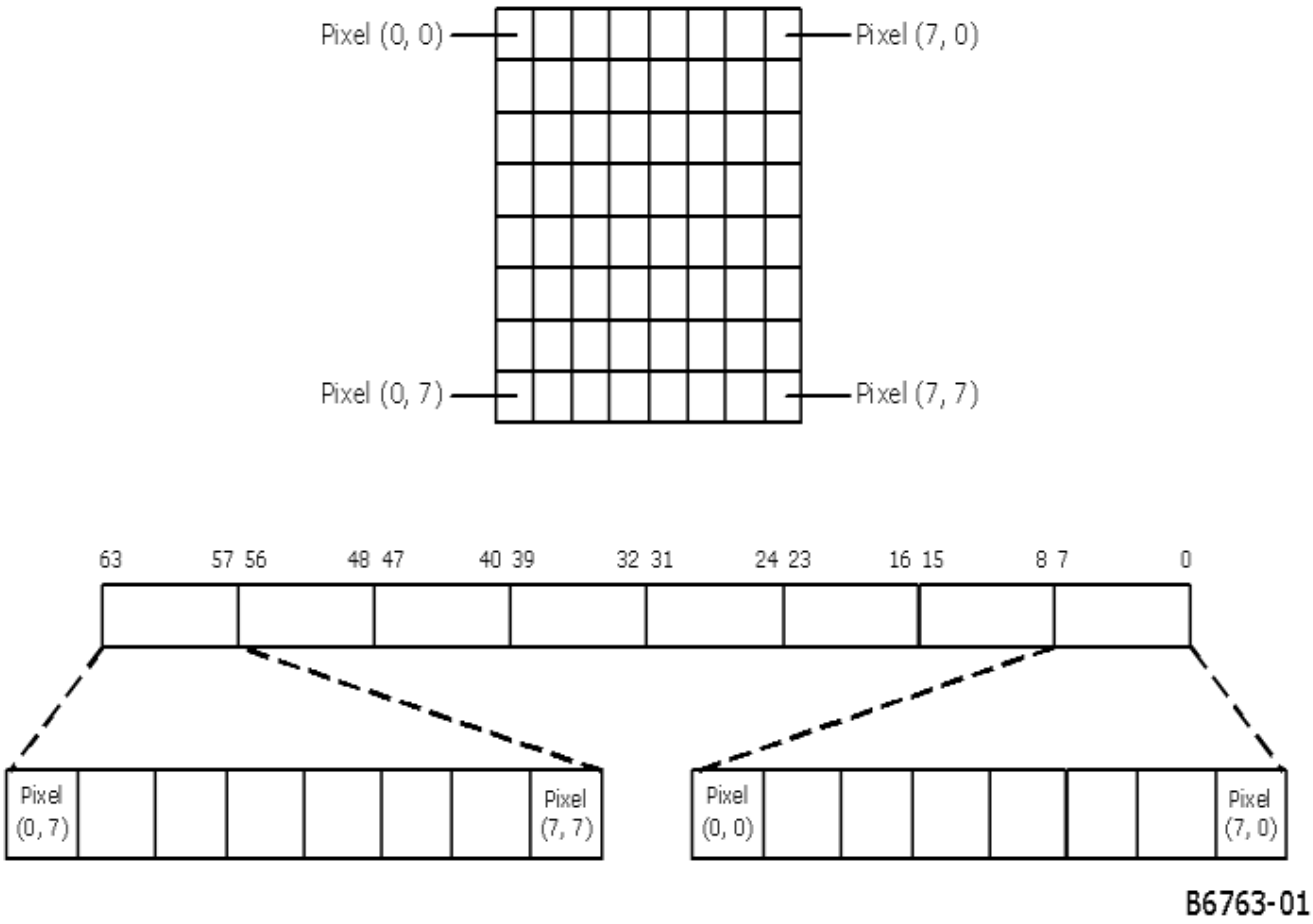
The color pattern data must exist within the frame buffer or Graphics aperture where the BLT engine may read it directly or it can be sent through the command stream. The pattern data must be located in linear memory.

Note also that the Color Pattern surface start Base Address, should always be Cache Line (64byte) aligned.

Monochrome pattern data is supplied by the command packet when it is to be used. As shown in figure below, the block of pattern graphics data always represents a block of 8x8 pixels. The bits or bytes of a block of pattern data may be organized in the frame buffer memory in only one of three ways, depending upon its color depth which may be 8, 16, or 32 bits per pixel (whichever matches the color depth to which the BLT engine has been set), or monochrome.

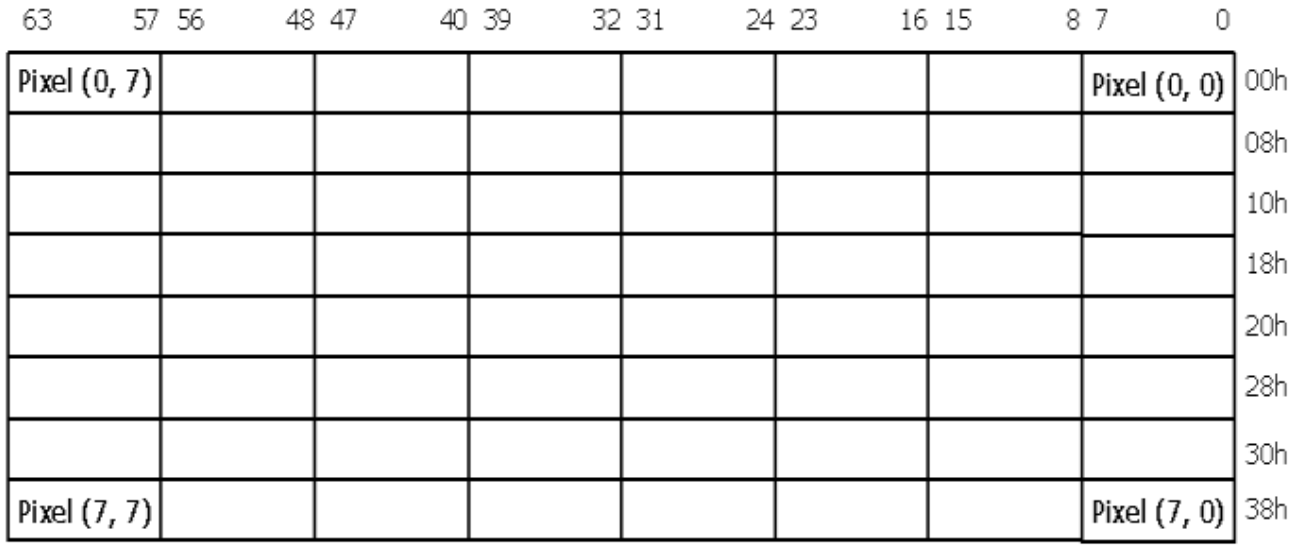
The maximum color pattern size is 256 bytes.

Pattern Data -- Always an 8x8 Array of Pixels



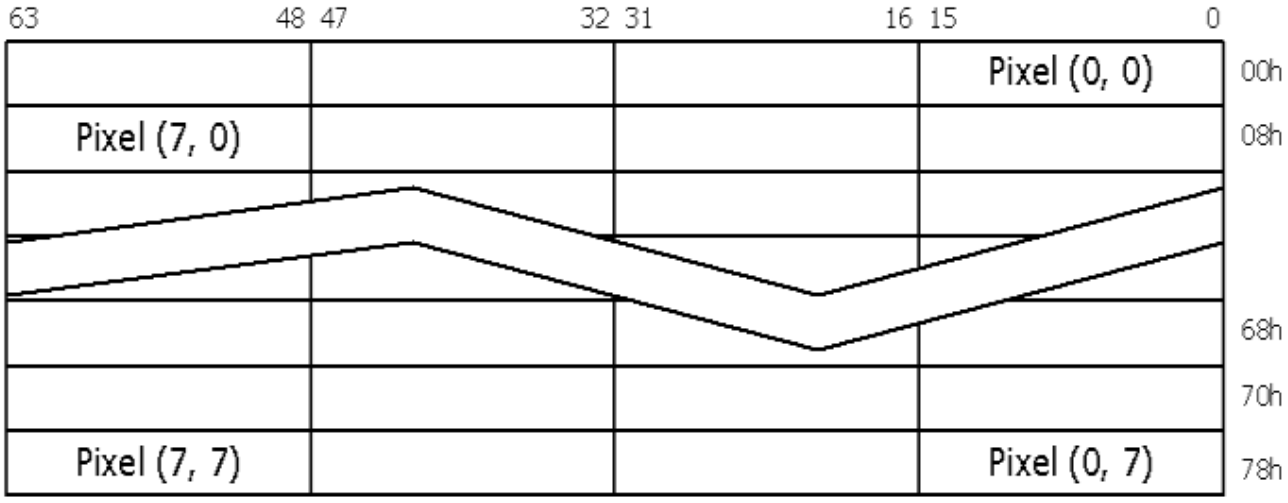
The Pattern Address Register is used to specify the address of the color pattern data at which the block of pattern data begins. The three least significant bits of the address written to this register are ignored, because the address must be in terms of quadwords. This is because the pattern must always be located on an address boundary equal to its size. Monochrome patterns take up 8 bytes, or a single quadword of space, and are loaded through the command packet that uses it. Similarly, color patterns with color depths of 8, 16, and 32 bits per pixel must start on 64-byte, 128-byte and 256-byte boundaries, respectively. The next 3 figures show how monochrome, 8bpp, 16bpp, and 32bpp pattern data , respectively, is organized in memory.

8bpp Pattern Data -- Occupies 64 Bytes (8 quadwords)



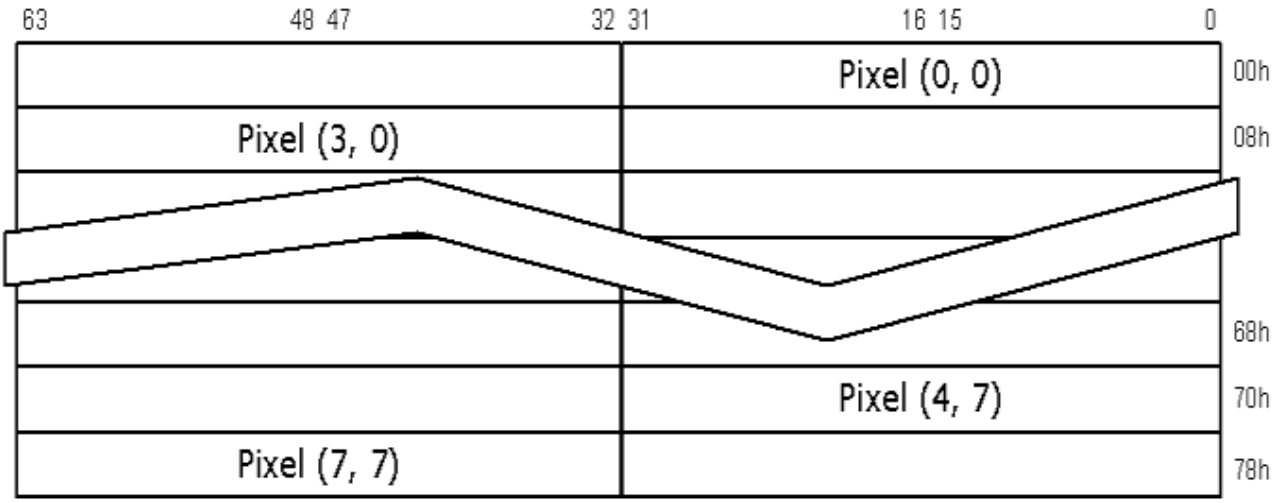
B6764-01

16bpp Pattern Data -- Occupies 128 Bytes (16 quadwords)



B6765-01

32bpp Pattern Data -- Occupies 256 Bytes (32 quadwords)



The opcode of the command packet specifies whether the pattern data is color or monochrome. The various bit-wise logical operations and per-pixel write-masking operations were designed to work with color data. In order to use monochrome pattern data, the BLT engine is designed to convert it into color through a process called "color expansion" which takes place as a BLT operation is performed. In color expansion, the single bits of monochrome pattern data are converted into one, two, or four bytes (depending on the color depth) of color data that are set to carry values corresponding to either the foreground or background color that have been specified for use in this process. The foreground color is used for pixels corresponding to a bit of monochrome pattern data that carry the value of 1, while the background color is used where the corresponding bit of monochrome pattern data carries the value of 0. The foreground and background colors used in the color expansion of monochrome pattern data can be set in the Pattern Expansion Foreground Color Register and Pattern Expansion Background Color Register.

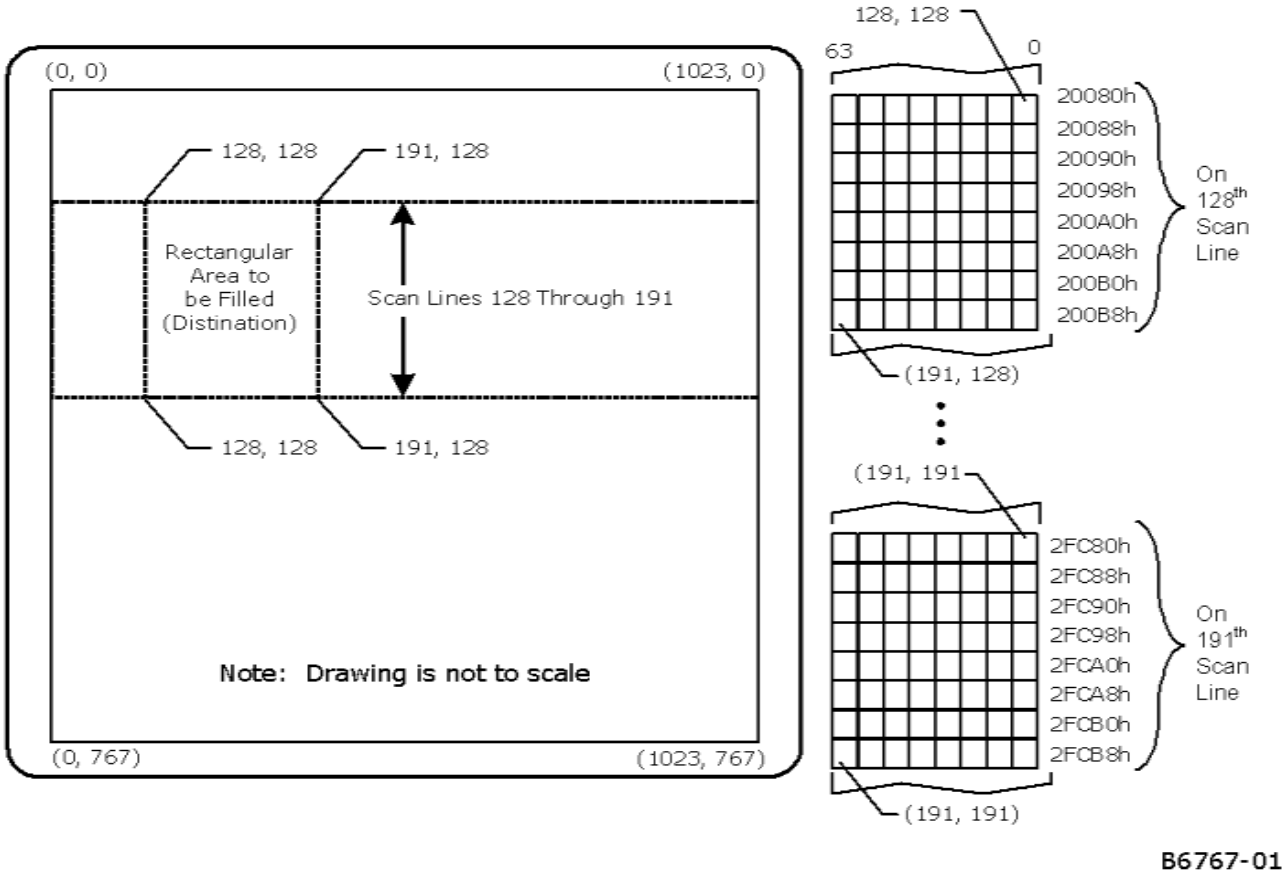
BLT Programming Examples

Pattern Fill -- A Very Simple BLT

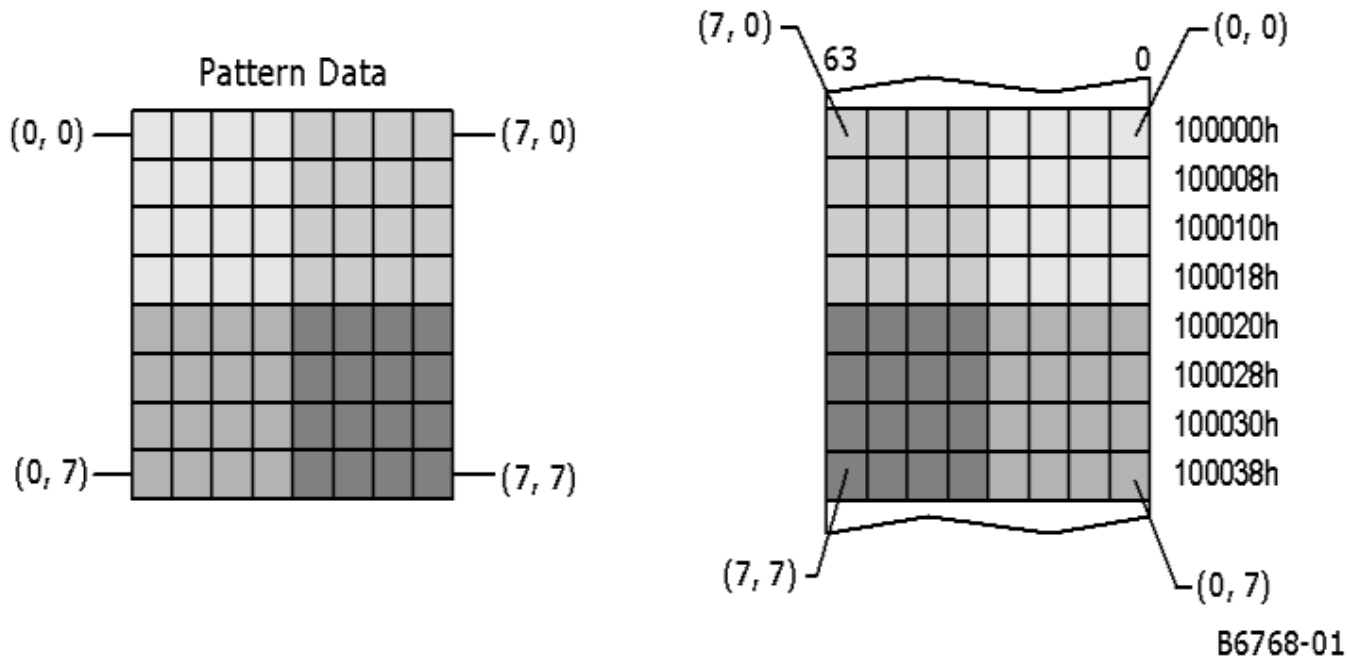
In this example, a rectangular area on the screen is to be filled with a color pattern stored as pattern data in off-screen memory. The screen has a resolution of 1024x768 and the graphics system has been set to a color depth of 8 bits per pixel.

On-Screen Destination for Example Pattern Fill BLT



As shown in the figure above, the rectangular area to be filled has its upper left-hand corner at coordinates (128, 128) and its lower right-hand corner at coordinates (191, 191). These coordinates define a rectangle covering 64 scan lines, each scan line's worth of which is 64 pixels in length -- in other words, an array of 64x64 pixels. Presuming that the pixel at coordinates (0, 0) corresponds to the byte at address 00h in the frame buffer memory, the pixel at (128, 128) corresponds to the byte at address 20080h.

Pattern Data for Example Pattern Fill BLT



As shown in figure above, the pattern data occupies 64 bytes starting at address 100000h. As always, the pattern data represents an 8x8 array of pixels.

The BLT command packet is used to select the features to be used in this BLT operation, and must be programmed carefully. The vertical alignment field should be set to 0 to select the top-most horizontal row of the pattern as the starting row used in drawing the pattern starting with the top-most scan line covered by the destination. The pattern data is in color with a color depth of 8 bits per pixel, so the dynamic color enable should be asserted with the dynamic color depth field should be set to 0. Since this BLT operation does not use per-pixel write-masking (destination transparency mode), this field should be set to 0. Finally, the raster operation field should be programmed with the 8-bit value of F0h to select the bit-wise logical operation in which a simple copy of the pattern data to the destination takes place. Selecting this bit-wise operation in which no source data is used as an input causes the BLT engine to automatically forego either reading source data from the frame buffer.

The Destination Pitch Register must be programmed with number of bytes in the interval from the start of one scan line's worth of destination data to the next. Since the color depth is 8 bits per pixel and the horizontal resolution of the display is 1024, the value to be programmed into these bits is 400h, which is equal to the decimal value of 1024.

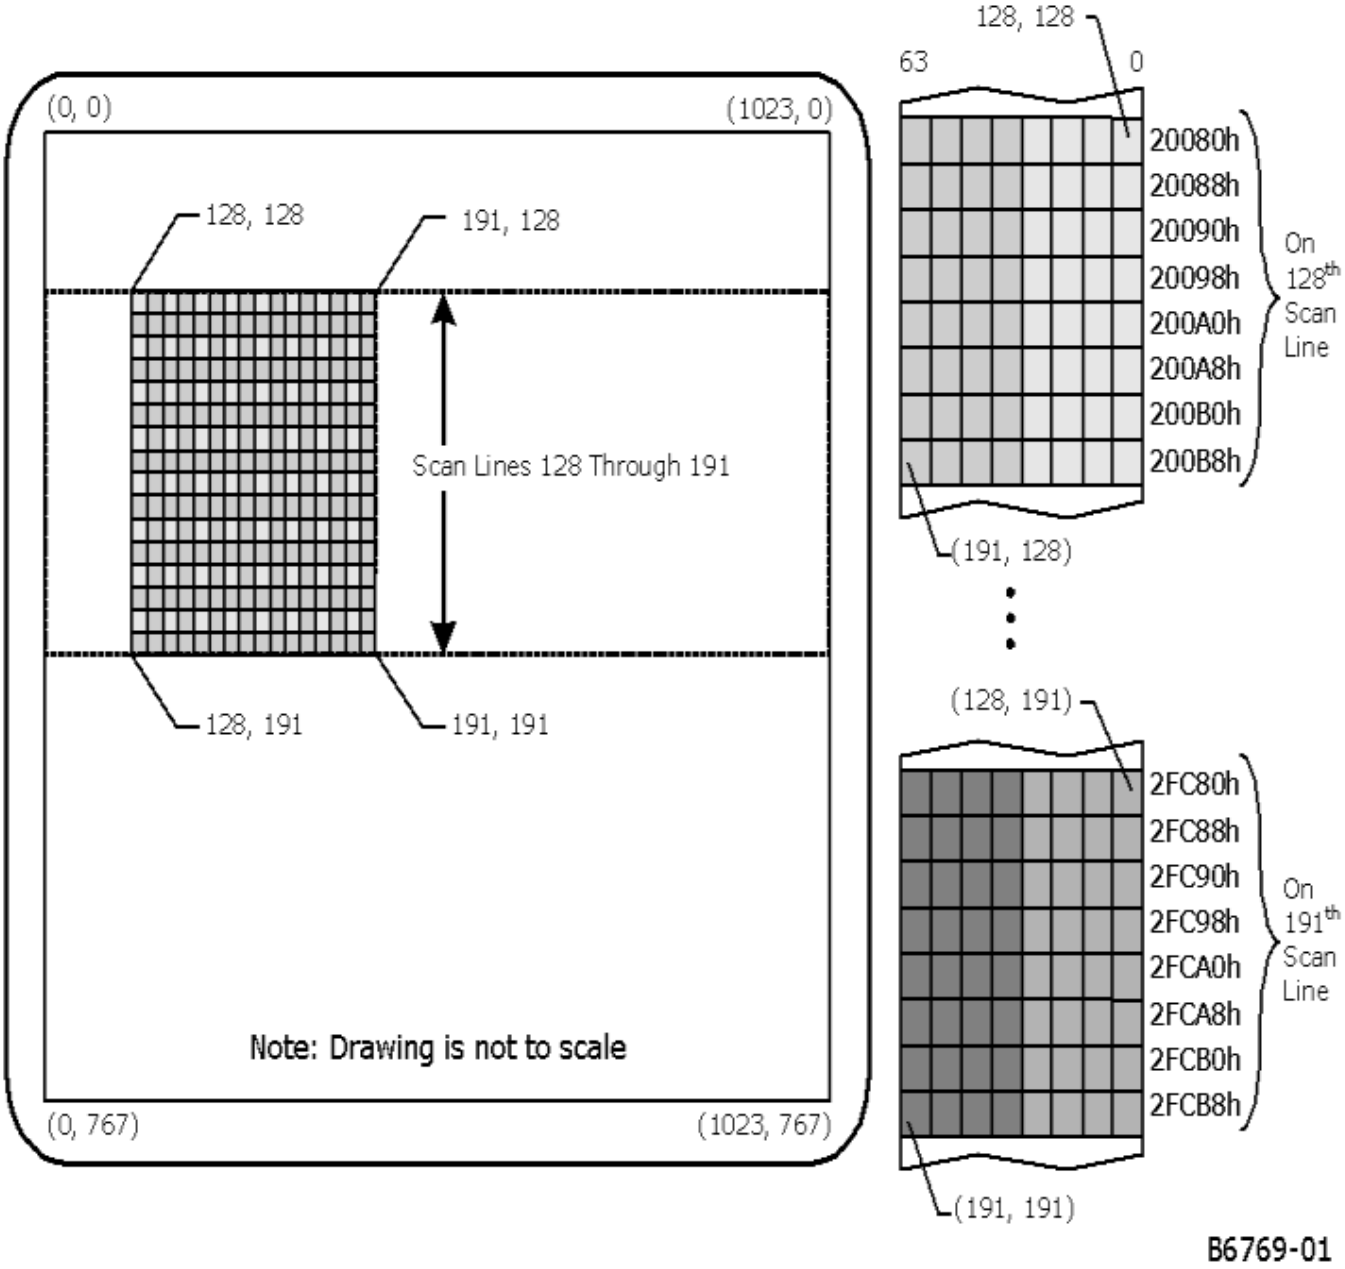
Bits [31:3] of the Pattern Address Register must be programmed with the address of the pattern data.

Similarly, bits [31:0] of the Destination Address Register must be programmed with the byte address at the destination that will be written to first. In this case, the address is 20080h, which corresponds to the byte representing the pixel at coordinates (128, 128).

This BLT operation does not use the values in the Source Address Register or the Source Expansion Background or Foreground Color Registers.

The Destination Width and Height Registers (or the Destination X and Y Coordinates) must be programmed with values that describe to the BLT engine the 64x64 pixel size of the destination location. The height should be set to carry the value of 40h, indicating that the destination location covers 64 scan lines. The width should be set to carry the value of 40h, indicating that each scan line's worth of destination data occupies 64 bytes. All of this information is written to the ring buffer using the PAT_BLT (or XY_PAT_BLT) command packet.

Results of Example Pattern Fill BLT

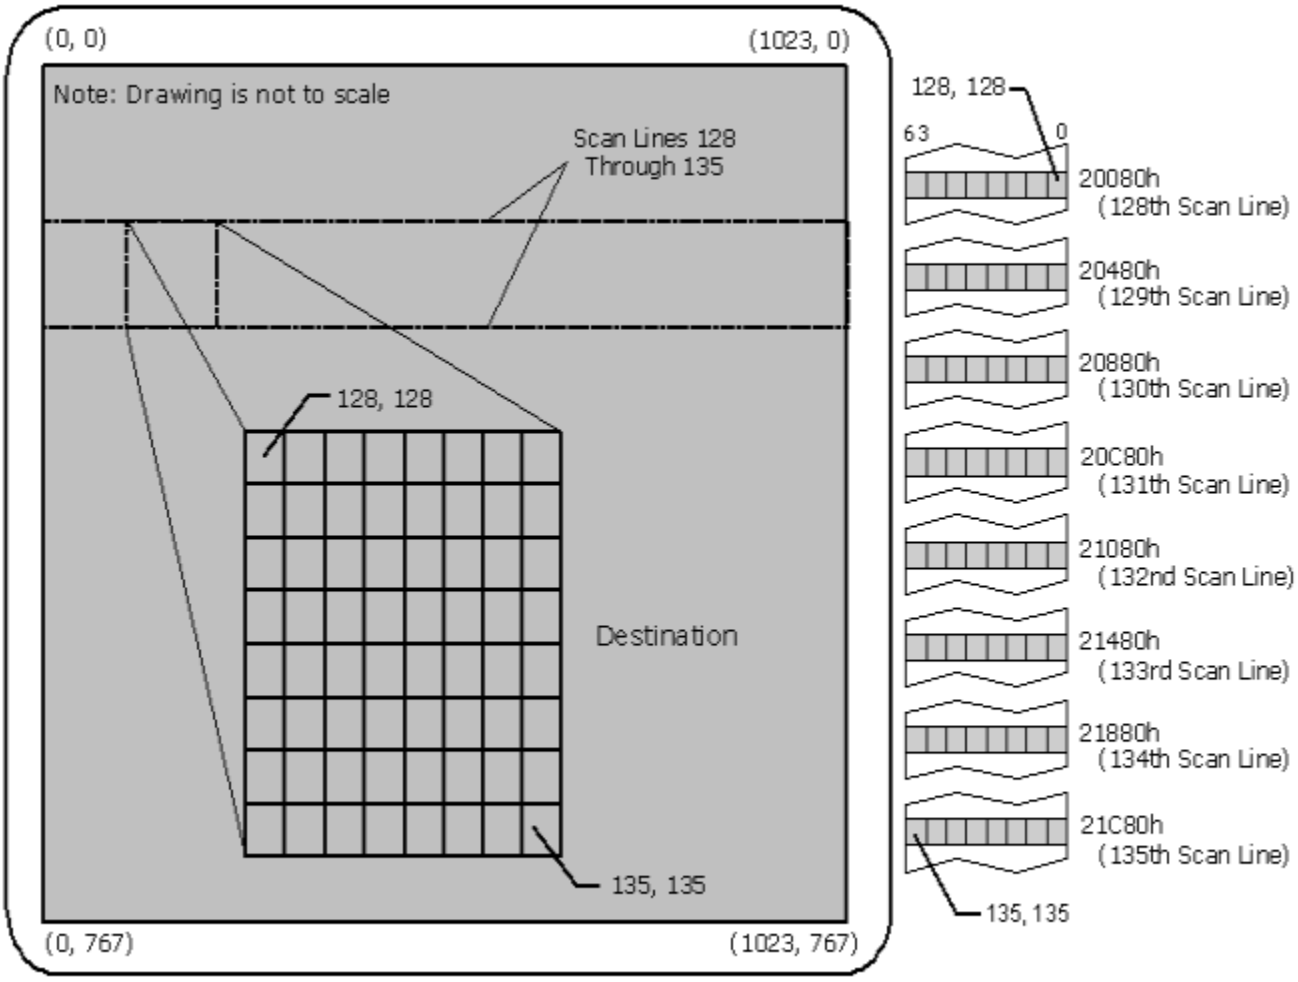


The figure above shows the end result of performing this BLT operation. The 8x8 pattern has been repeatedly copied ("tiled") into the entire 64x64 area at the destination.

Drawing Characters Using a Font Stored in System Memory

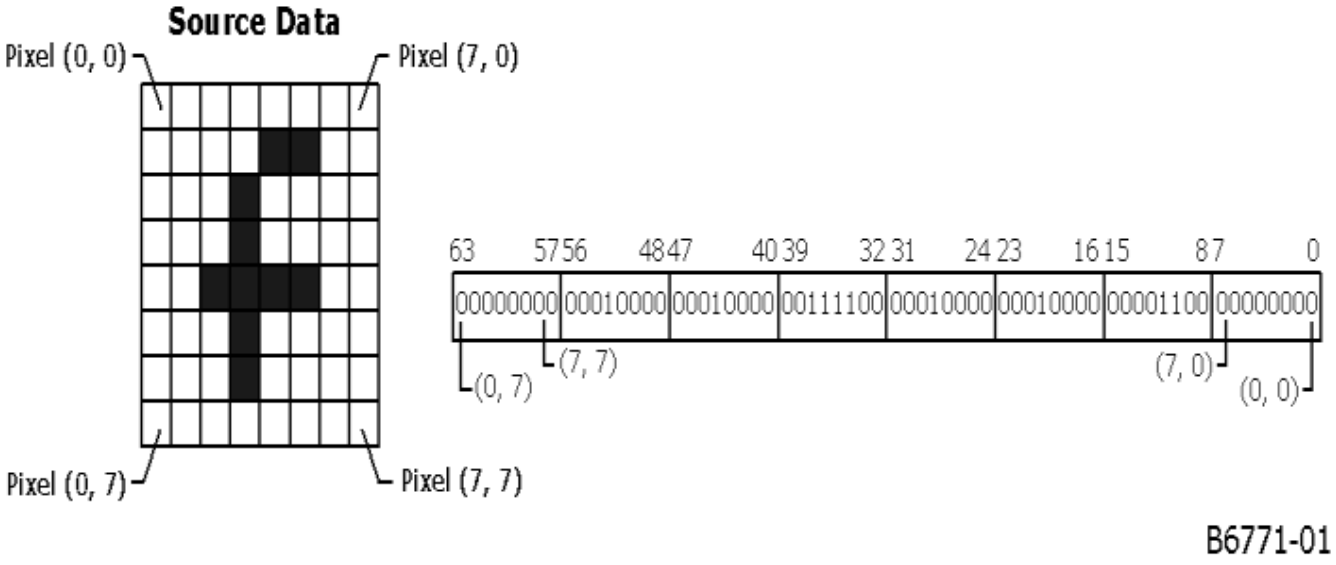
In this example BLT operation, a lowercase letter "f" is to be drawn in black on a display with a gray background. The resolution of the display is 1024x768, and the graphics system has been set to a color depth of 8 bits per pixel.

On-Screen Destination for Example Character Drawing BLT



The figure above shows the display on which this letter "f" is to be drawn. As shown in this figure, the entire display has been filled with a gray color. The letter "f" is to be drawn into an 8x8 region on the display with the upper left-hand corner at the coordinates (128, 128).

Source Data in System Memory for Example Character Drawing BLT



The figure above shows both the 8x8 pattern making up the letter "f" and how it is represented somewhere in the host's system memory -- the actual address in system memory is not important. The letter "f" is represented in system memory by a block of monochrome graphics data that occupies 8 bytes. Each byte carries the 8 bits needed to represent the 8 pixels in each scan line's worth of this graphics data. This type of pattern is often used to store character fonts in system memory.

During this BLT operation, the host CPU will read this representation of the letter "f" from system memory, and write it to the BLT engine by performing memory writes to the ring buffer as an immediate monochrome BLT operand following the BLT_TEXT command. The BLT engine will receive this data through the command stream and use it as the source data for this BLT operation. The BLT engine will be set to the same color depth as the graphics system -- 8 bits per pixel, in this case. Since the source data in this BLT operation is monochrome, color expansion must be used to convert it to an 8 bpp color depth. To ensure that the gray background behind this letter "f" is preserved, per-pixel write masking will be performed, using the monochrome source data as the pixel mask.

The BLT Setup and Text_immediate command packets are used to select the features to be used in this BLT operation. Only the fields required by these two command packets must be programmed carefully. The BLT engine ignores all other registers and fields. The source select field in the Text_immediate command must be set to 1, to indicate that the source data is provided by the host CPU through the command packet. Finally, the raster operation field should be programmed with the 8-bit value CCh to select the bit-wise logical operation that simply copies the source data to the destination. Selecting this bit-wise operation in which no pattern data is used as an input, causes the BLT engine to automatically forego reading pattern data from the frame buffer.

The Setup Pattern/Source Expansion Foreground Color Register to specify the color with which the letter "f" will be drawn. There is no Source address. All scan lines of the glyph are bit packed and the clipping is controlled by the ClipRect registers from the SETUP_BLT command and the Destination Y1, Y2, X1, and

X2 registers in the TEXT_BLT command. Only the pixels that are within (inclusive comparisons) the clip rectangle are written to the destination surface.

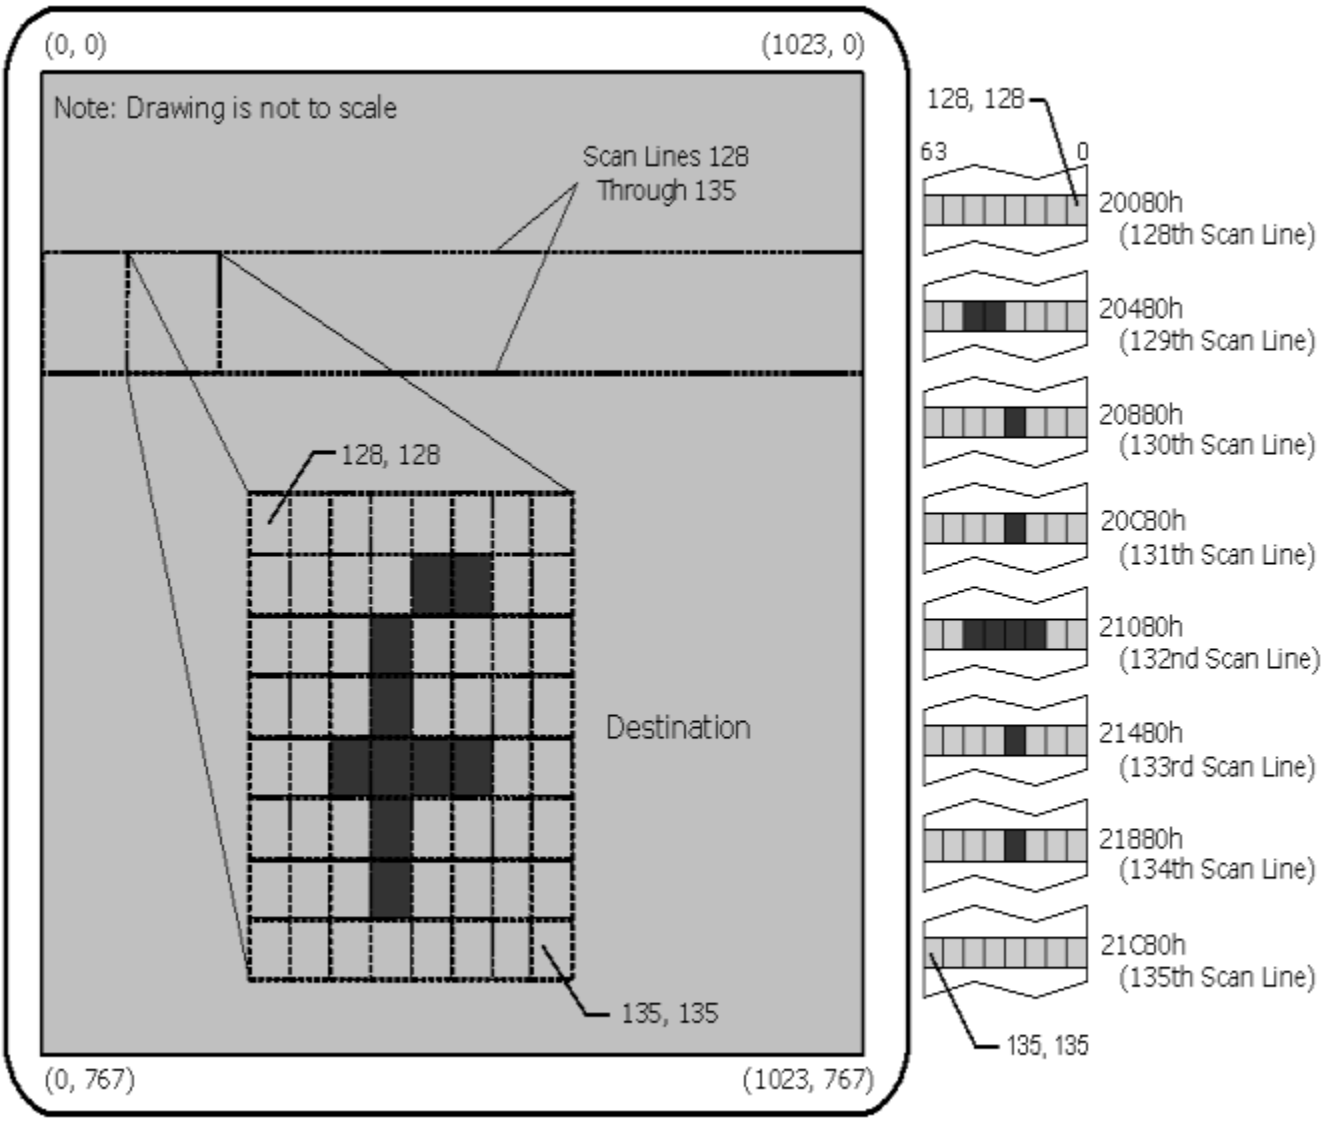
The Destination Pitch Register must be programmed with a value equal to the number of bytes in the interval between the first bytes of each adjacent scan line's worth of destination data. Since the color depth is 8 bits per pixel and the horizontal resolution of the display is 1024 pixels, the value to be programmed into these bits is 400h, which is equal to the decimal value of 1024. Since the source data used in this BLT operation is monochrome, the BLT engine will not use a byte-oriented pitch value for the source data.

Since the source data is monochrome, color expansion is required to convert it to color with a color depth of 8 bits per pixel. Since the Setup Pattern/Source Expansion Foreground Color Register is selected to specify the foreground color of black to be used in drawing the letter "f", this register must be programmed with the value for that color. With the graphics system set for a color depth of 8 bits per pixel, the actual colors are specified in the RAMDAC palette, and the 8 bits stored in the frame buffer for each pixel actually specify the index used to select a color from that palette. This example assumes that the color specified at index 00h in the palette is black, and therefore bits [7:0] of this register should be set to 00h to select black as the foreground color. The BLT engine ignores bits [31:8] of this register because the selected color depth is 8 bits per pixel. Even though the color expansion being performed on the source data normally requires that both the foreground and background colors be specified, the value used to specify the background color is not important in this example. Per-pixel write-masking is being performed with the monochrome source data as the pixel mask, which means that none of the pixels in the source data that will be converted to the background color will ever be written to the destination. Since these pixels will never be seen, the value programmed into the Pattern/Source Expansion Background Color Register to specify a background color is not important.

The Destination Width and Height Registers are not used. The Y1, Y2, X1, and X2 are used to describe to the BLT engine the 8x8 pixel size of the destination location. The Destination Y1 and Y2 address (or coordinate) registers must be programmed with the starting and ending scan line address (or Y coordinates) of the destination data. This address is specified as an offset from the start of the frame buffer of the scan line at the destination that will be written to first. The destination X1 and X2 registers must be programmed with the starting and ending pixel offsets from the beginning of the scan line.

This BLT operation does not use the values in the Pattern Address Register, the Source Expansion Background Color Register, or the Source Expansion Foreground Color Register.

Results of Example Character Drawing BLT



The preceding shows the end result of performing this BLT operation. Only the pixels that form part of the actual letter "f" have been drawn into the 8x8 destination location on the display, leaving the other pixels within the destination with their original gray color.

Fast Copy Engine

Fast Copy Engine is capable of performing sub-resource copy or fill operation saturating the full memory bandwidth. It is a resource processor that can copy from a source of arbitrary format. Fast Copy Engine is capable of understanding the concept of resource and sub-resources. It can support data transfer between overlapping surfaces. It can support state-full compression and decompression. Copy Engine supports both linear as well as tiled memory and operate on both system as well as local memory (when it is not a UMA system). In case of UMA system there is just a single memory.

Fast Copy Engine can be used for paging in or paging out resources to and from GPU. It also supports Fast Clear and regular clear operation of AUX enabled surfaces. It can be used to perform resolve operation on compressed surfaces. Copy Engines can operate on 2D surfaces defined using pixel coordinates as well as linear surfaces defined using virtual addresses.

Fast Copy Engine performance scales with number of memory slices in the system.

Copy workloads are submitted to the appropriate copy engines by the software through copy queues. BLT command streamers parses the commands and submits them to Fast Copy Engine. Copy Engines are split into two parts:

1. Copy Engine Front-end - splits an incoming command/BLIT into smaller commands/sub-blits
2. Copy Engine Back-end - it takes sub-blits and performs actual cachline read/write operations

Performance scaling of the Fast Copy Engine is achieved by increasing the number of copies of Back-end (Sub-copy Engine) attached to the single front-end of the fast copy engine. Fast copy engine can handle sub-blit level dependencies (producer consumer relationship). Software may have to insert appropriate flushes between commands to handle some dependencies not supported by copy engine hardware, as defined at a later section.

BLT Instruction Overview

There are two blitter back-ends behind the single engine viz. Classical Blitter or Legacy Blitter Engine and Fast Copy Engine. Each of which operates on a separate mutually exclusive set of instructions. Commands for both the back-ends can be submitted to the same Blitter Command Streamer and based on the command it is passed on to the appropriate back-end and executed there.

Each instruction consists of multiple dwords, where first dword is the header, which can identify the type of instruction, instruction opcode, length of instruction etc. Header may contain additional instruction fields as well. Fields may sometime need more than one dword.

Most of the instructions can operate independently without state other than some Legacy Blitter commands involving clip rectangles that programs some BRs (Blitter Registers) before executing those commands.

There are specific MMIO based config registers that configures how Legacy Blitter or Fast Copy Engine is expected to operate.

Legacy Blitter uses cache, so unless a flush is inserted after an instruction there is no guarantee of final data reaching the memory.

The flush is common for both the backends. Once a flush is sent command streamer stops sending further commands to the back-ends and back-ends ensure that when the current commands being processed by the back-ends are completed flush dones are sent to blitter command streamer.

The actual commands have been listed out in a later section.

BLT Engine State

Most of the BLT instructions are state-free, which means that all states required to execute the command is within the instruction. If clipping is not used, then there is no shared state for many of the BLT instructions. This allows the BLT Engine to be shared by many drivers with minimal synchronization between the drivers.

Instructions which share state are:

All instructions that are X,Y commands and use the Clipping Rectangle by asserting the Clip Enable field

All XY_Setup Commands (XY_SETUP_BLT and XY_SETUP_MONO_PATTERN_SL_BLT, XY_SETUP_CLIP_BLT) load the shared state for the following commands:

XY_PIXEL_BLT	(Negative Stride (=Pitch) Not Allowed)
XY_SCANLINES_BLT	
XY_TEXT_BLT	(Negative Stride (=Pitch) Not Allowed)
XY_TEXT_IMMEDIATE_BLT	(Negative Stride (=Pitch) Not Allowed)

State registers that are saved & restored in the Logical Context:

BR1+ Setup Control (Solid Pattern Select, Clipping Enable, Mono Source Transparency Mode, Mono Pattern Transparency Mode, Color Depth[1:0], Raster Operation[7:0], & Destination Pitch[15:0]) + 32bpp Channel

Mask[1:0], Mono / Color Pattern

BR05 Setup Background Color

BR06 Setup Foreground Color

BR07 Setup Pattern Base Address

BR09 Setup Destination Base Address

BR20 DW0 for a Monochrome Pattern

BR21 DW1 for a Monochrome Pattern

BR24 ClipRectY1'X1

BR25 ClipRectY2'X2

The definition of each of the above registers which are part of logical context and are saved and restored during context save and restore are found in "BLT Engine Instruction Field Definitions" section.

Device Cache Coherency: Render & Texture Caches

Software must initiate cache flushes to enforce coherency between the render and texture caches, i.e., both the render and texture caches must be flushed before a BLT destination surface can be reused as a texture source. Color sources and destinations use the render cache, while patterns and monochrome sources use the texture cache.

Verbatim Copy operation

Verbatim Copy is the special copy operation defined for compressed surface copy where both the main surface data and the associated CCS data are moved as it is from one location to another. During this operation main surface data copy and CCS data copy are performed sequentially. Driver needs to use two separate commands, XY_FAST_COPY_BLT to copy the main surface data and XY_CTRL_SURF_COPY_BLT to copy the CCS surface, together for verbatim copy. In case of regular compressed data access from Copy Engine, read data from source is always made available to copy engine as fully decompressed data and Copy Engine writes fully decompressed data back to memory and if destination compression is required this data is again compressed and written to memory. The compressed write causes both CCS and main surface write data to be modified. In case of verbatim copy "data read" operation from source the data does not decompressed before sending to Copy Engine. Driver needs to set "Enable Compressed Surface Read" bit in the XY_FAST_COPY_BLT command to enable this special operation. In case of verbatim copy "data write" operation to destination surface this "raw" compressed data is sent out and this flow can be enabled by driver by setting the "Enable Compressed Surface Write" bit in the XY_FAST_COPY_BLT command.

These two commands must be used in a pair and the sequence in which the two commands must be used during verbatim copy operation varies based on whether it is being used for swap-in (moving data from local memory to system memory) or swap-out (moving data from system memory to local memory) operation for compressed data. In case of swap-out operation the sequence required is XY_FAST_COPY_BLT followed by XY_CTRL_SURF_COPY_BLT. In case of swap-in operation the sequence required is XY_CTRL_SURF_COPY_BLT followed by XY_FAST_COPY_BLT.

During verbatim copy the copy rectangles used for XY_CTRL_SURF_COPY_BLT and XY_FAST_COPY_BLT must be same. They must also use same BPP and pitch. Using base address X1, X2, Y1, Y2 from XY_FAST_COPY_BLT command start address and range is calculated.

BLT Engine Instructions

The Instruction Target field is used as an opcode by the BLT Engine state machine to qualify the control bits that are relevant for executing the instruction. The descriptions for each DWord and bit field are contained in the *BLT Engine Instruction Field Definition* section. Each DWord field is described as a register, but none of these registers can be written or read through a memory mapped location; they are internal state only.

BLT Programming Restrictions

Overlapping Source/Destination BLTs:

For all products *negative pitch* programming is allowed only when the source and destination surfaces are of the same type: linear source to linear destination copy, or tiled source to tiled destination copy. This is a must requirement. In such cases:

- Both the pitches must be programmed to be a negative value, if the source and destination surfaces are overlapping.
- Either of the pitches can be programmed to a negative value if required to do mirroring, but only if the complete source and destination surfaces are not overlapping anywhere on the surfaces.

Description
For the XY_FAST_COPY_BLT and XY_BLOCK_COPY_BLT instruction, these restrictions apply: When two sequential fast copy blits have different source surfaces, but their destinations refer to the same destination surface and therefore destinations overlap, a Flush must be inserted between the two blits. For two sequential fast copy blits when the source of the second blit is the destination of the first blit or they overlap a Flush must be inserted between the two blits.
For Tiled surfaces, the pitch length is always Cacheline aligned (64-byte multiple), as Tile surface pitches must be a multiple of Tile widths, which are always cacheline aligned. For XY_FAST_COPY_BLT command (X1, X2) and (Y1, Y2) must be programmed different values so that start pixel/end pixel and start line/end line do not coincide.

Legacy Blits:

The following condition must be avoided when programming the BLT engine: Linear surfaces with a cache line in scan line Y for the source stream overlapping with a cache line in scan line Y-1 for the dest stream (=> non-aligned surface pitches). The cache coherency rules combined with the Blitter data consumption rules result in UNDEFINED operation.

All reserved fields must be programmed to 0s.

When using monosource or text data (bit/byte/word aligned): Do not program pixel widths greater than 32,745 pixels.

The other way to do this is driver should always program a dummy 3D.

NON-PIPELINE state following the BLT commands:

Description
For Monosource and Color Pattern surfaces, and also linear color source and destination surfaces, the start **Base Address** programmed should always be Cache Line (64 byte) aligned.

Programming Note	
Context:	Fast Copy Blitter + Frame Buffer Compression
Fast Copy, Block Copy and Fast Color workloads targeting the Front Buffer with FBC enabled is not supported.	

Programming Note	
Context:	XY_FAST_COPY_BLT command programming restriction
XY_FAST_COPY_BLT command's (X1, Y1), (X2, Y2) must be programmed such way so that neither W nor H of the surface to copy are "0".	

Programming Note	
Context:	Blitter
Support for Tile-Yf format has been removed, so Blitter should not be programmed to support Tile-Yf for source or destination tiling.	

Programming Note	
Project:	
Context:	Blitter (XY_BLOCK_COPY_BLT, XY_FAST_COLOR_BLT commands)
X offset, Y offset and (X1, Y1), (X2, Y2) values must be programmed so that X coordinate values when added to X offset remains within the surface boundary (16384 pixels). Similarly Y coordinate values when added to Y offset must remain within the surface boundary (16384 lines). Copy operation between two overlapping surfaces are supported only when the base address and pitch of both the source and destination surfaces are identical, irrespective of the surface formats.	

2D (XY) BLT Instructions

Most BLT instructions (prefixed with "XY_") use 2D X,Y coordinate specifications vs. lower-level linear addresses These instructions also support simple 2D clipping against a clip rectangle. The top and left Clipping coordinates are inclusive. The bottom and right coordinates are exclusive. The BLT Engine performs a trivial reject for all CLIP BLT instructions before performing any accesses.

Negative destination and source coordinates are supported. In the case of negative source coordinates, the destination X1 and Y1 are modified by the absolute value of the negative source coordinate before the destination clip checking and final drawing coordinates are calculated. The absolute value of the source negative coordinate is added to the corresponding destination coordinate. The BLT engine clipping also checks for (DX2 [or = DX1) or (DY2 [or = DY1) after this calculation and if true, then the BLT is totally rejected.

Source and destination pitches have the additional explanation given next. The below statements are applicable for pitch field in all of the Blit commands:

1. For Linear surfaces, the pitch is programmed in bytes. For Tiled surfaces the pitch programmed is in Dwords count.
2. For Tiled surfaces this pitch is of 512Byte granularity for Tile-X: This means the tiled-x surface pitch can be (512, 1024, 1536, 2048...)/4 (in Dwords).
3. For Tiled surfaces this pitch is of 128B granularity for Tile-Y/Yf and of 512B granularity for Tile-Ys: This means the tiled-y surface pitch can be (128, 256, 384, 512...)/4 (in Dwords).
4. Another way to indicate this is, for tiled surfaces, the pitch is programmed in Dwords and is an integral multiple of the tile width.

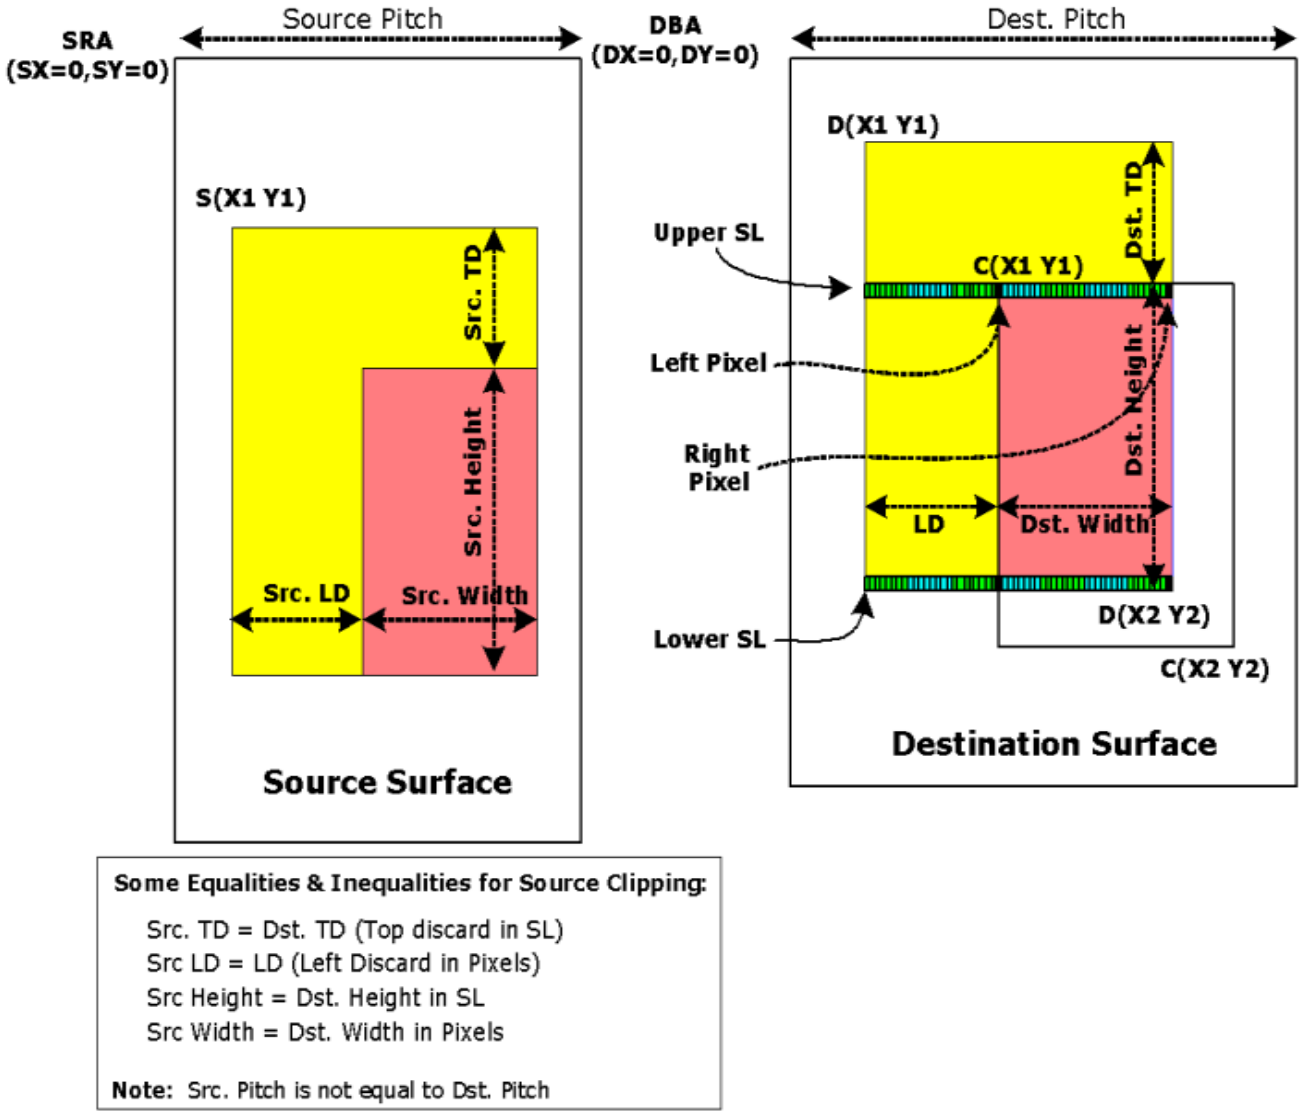
Some Equalities & Inequalities for Source Clipping



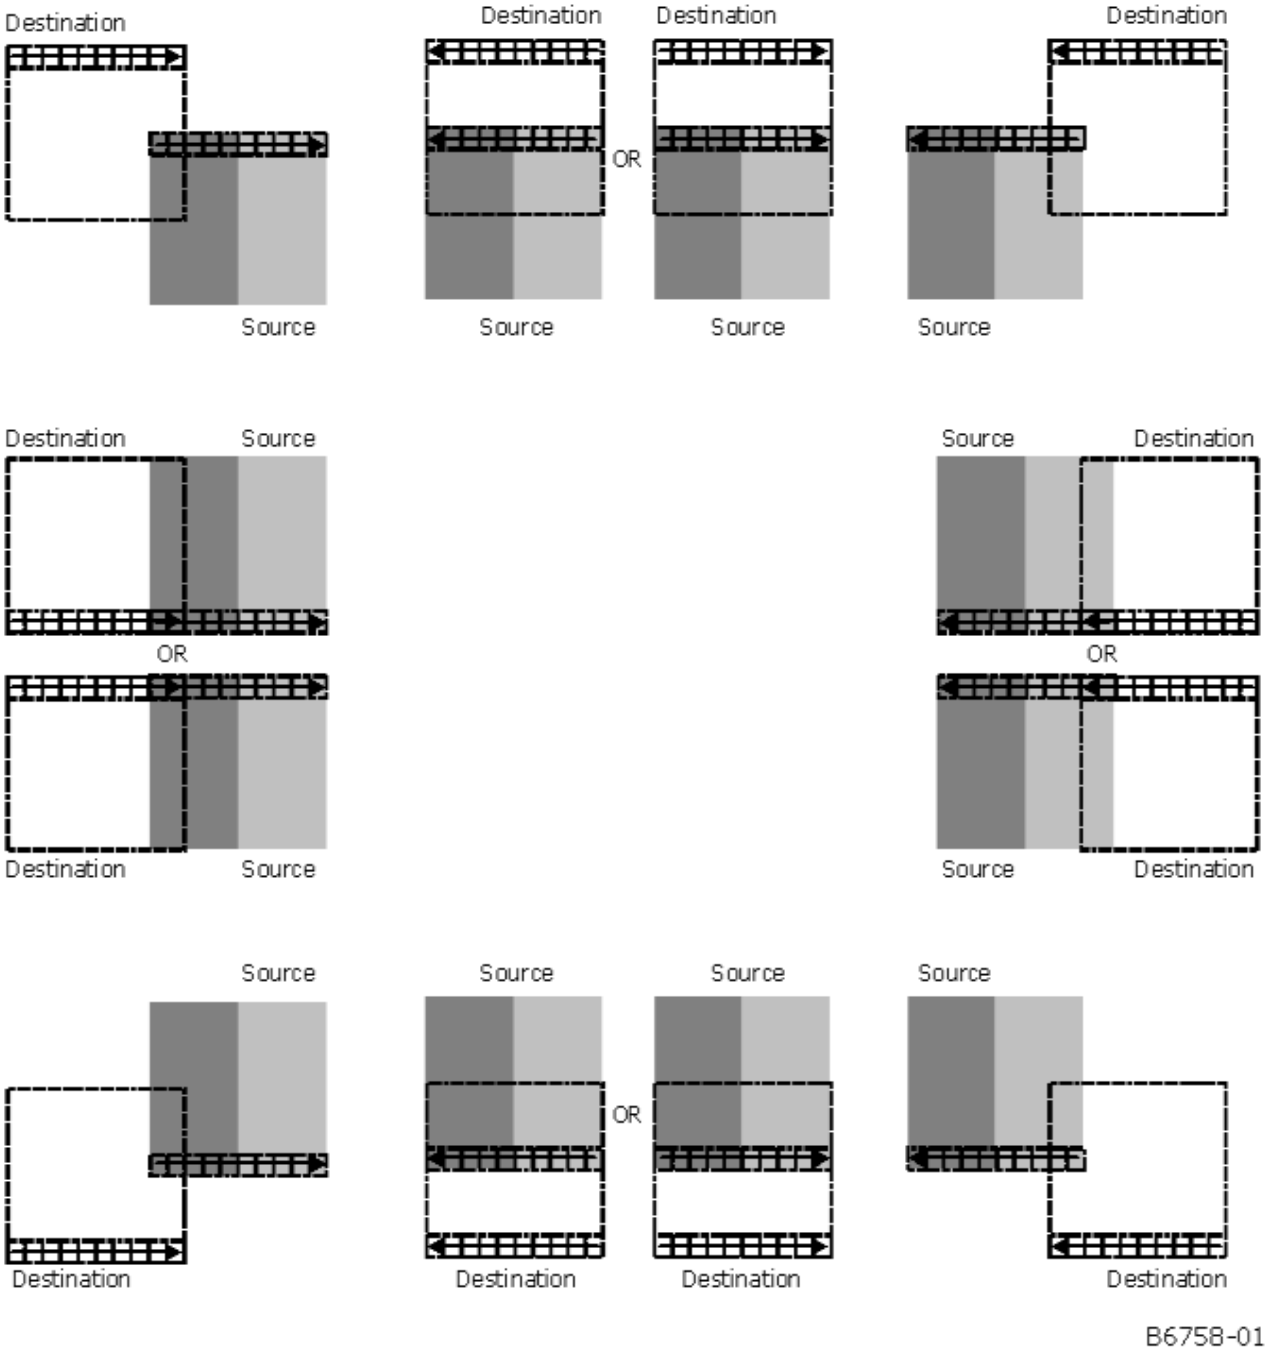
DX1, DY1, CX1, and CY1 are inclusive, while DX2, DY2, CX2, and CY2 are exclusive.

Destination pixel address = (Destination Base Address + (Destination Y coordinate * Destination pitch) + (Destination X coordinate * bytes per pixel)).

Source pixel address = (Source Base Address + (Source Y coordinate * Source pitch) + (Source X coordinate * bytes per pixel)).

Since there is 1 set of Clip Rectangle registers, the Interrupt Ring BLT commands either MUST NEVER enable clipping with these commands and never use the XY_Pixel_BLT, XY_Scanline_BLT, nor XY_Text_BLT commands or it must use context switching. The Interrupt rings can also use the non-clipped, linear address commands specified before this section.

The base addresses plus the X and Y coordinates determine if there is an overlap between the source and destination operands. If the base addresses of the source and destination are the same and the Source X1 is less than Destination X1, then the BLT Engine performs the accesses in the X-backwards access pattern. There is no need to look for an actual overlap. If the base addresses are the same and Source Y1 is less than Destination Y1, then the scan line accesses are performed backwards.



BLT Engine Instruction Field Definitions

This section describes the BLT Engine instruction fields. These descriptions are in the format of register descriptions. These registers are internal and are not readable. Some of these registers are state that is saved and restored for supporting separate software threads.

AVP

The AV1 Codec Pipeline (AVP) is a fixed function hardware video codec responsible for decoding AV1 (AOMedia Video 1) video streams.

AVP Register Definitions

The Message Channel Interface is a read-only bus used to access the AVP status registers. All registers are 32 bits where reserved bits return a value of zero and subtractive-decode is used to return 0x0000 for all register holes.

Register Attributes Description

Host Register Attributes gives the defined register tags and their description.

Host Register Attributes

Tag	Name	Description
R/W	Read/Write	Bit is read and writeable.
R/SW	Read/Special Write	Bit is readable. Write is only allowed once after a reset.
RO	Read Only	Bit is only readable, but writes have no effects.
WO	Write Only	Bit is only writeable, reads return zeros.
RV	Reserved	Bit is reserved and not visible. Reads will return 0, and writes have no effect.
NA	Not Accessible	This bit is not accessible.

AVP Decoder Register Map

This documents all AVP Decoder MMIO Registers.

AVP Decoder Register Descriptions

Reserved.

AVP Command Summary

The AV1 is configured through a set of batch commands defined in the following sections. The software driver builds a frame level workload using these commands and stores these workloads in graphics memory where they are fetched by the Video Command Streamer (VCS) and presented to the AVP for processing. The commands are processed by the Workload Parser within the AVP and the hardware is

configured by the Workload Parser prior to each frame level encode or decode. A workload is defined as a set of commands necessary to encode or decode one frame.

The software driver is required to read the AVP disable fuse to determine if the AVP is enabled. If it is disabled, then the software driver must not enable AVP batch commands to be sent to the AVP or a hang event may occur. Only when the AVP is enabled through the fuse, should the batch commands be sent to the AVP.

AVP Workload Command Model

DWord0 of each command is defined in AVP DWord0 Command Definition. The AVP is selected with the **Media Instruction Opcode "8h**" for all AVP Commands.

HCP DWord0 Command Definition

DWord	Bits	Description
0	31:29	**Command Type** = PARALLEL_VIDEO_PIPE = 3h
	28:27	**Pipeline Type** = 2h
	26:23	**Media Instruction Opcode = Codec/Engine Name** = AVP = 8h
	22:16	**Media Instruction Command** = <*see* HCP Media Instruction Commands (Opcode=7h)>
	15:12	**Reserved: MBZ**
	11:0	**Dword Length** (Excludes Dwords 0, 1) = <*command length*>

Each AVP command has assigned a media instruction command as defined in AVP Media Instruction Commands (Opcode=8h).

AVP Media Instruction Commands (Opcode=8h)

Media Instruction Command	Command DWord0 [22:16]	Mode	Scope
AVP_PIPE_MODE_SELECT	0h	Dec	Picture
AVP_SURFACE_STATE	1h	Dec	Picture
AVP_PIPE_BUF_ADDR_STATE	2h	Dec	Picture

AVP_TILE_CODING	15h	Dec	Tile
Reserved	16h-1Fh		
AVP_BSD_OBJECT_STATE	20h	Dec	Tile
Reserved	21h-31h		
Reserved	33h-7Fh		

AVP Command Sequence

The AV1 is configured for encoding or decoding through a set of batch commands defined in the following sections. The software driver builds a frame level workload using these commands and stores these workloads in graphics memory where they are fetched by the Video Command Streamer (VCS) and presented to the AVP for processing. The commands are processed by the Workload Parser within the AVP and the hardware is configured by the Workload Parser prior to each frame level encode or decode. A workload is defined as a set of commands necessary to encode or decode one frame.

The software driver is required to read the AVP disable fuse to determine if the AVP is enabled. If it is disabled, then the software driver must not enable AVP batch commands to be sent to the AVP or a hang event may occur. Only when the AVP is enabled through the fuse, should the batch commands be sent to the AVP.

AVP Command Sequence Examples for Decoder

AV1 workload is based upon a single tile decode. There are no states saved between tile decodes in the AVP.

The following programming sequence will be used by single pipe decode.

«Start Workload»	
|	

VD_CONTROL (AVP_Pipe_Initialization)	AVP PIpe Reset
|	
AVP_PIPE_MODE_SELECT	AVP Pipe Setup
|	

AVP_SURFACE_STATE (Multiple)	Frame Level Commands
AVP_PIPE_BUF_ADDR_STATE	Frame Level Commands
AVP_IND_OBJ_BASE_ADDR_STATE	Frame Level Commands
AVP_PIC_STATE	Frame Level Commands
AVP_SEGMENT_STATE	Frame Level Commands
AVP_INLOOP_FILTER_STATE	Frame Level Commands
|	
AVP_TILE_CODING	Tile Level Commands
|	

AVP_BSD_OBJECT	Decode Start
|	
« Tile Done »	Decode Finish
|	
VD_CONTROL (AVP_Memory_Implicit_Fush)	HW Data Flush to Memory
|	
«End Workload»	

Each tile should be programmed independently

AVP Buffer Size Requirements

This documents all the Memory Buffer Size Requirement and Media Internal Storage Programming.

The following tables indicate AV1 rowstore size requirement.

The number below indicates is number of cacheline per SB (SB can be 64x64 or 128x128).

The rowstore data can be stored in Internal Media Storage.

To allocate the following: **Total CLs = (#CLs_per_SB * num_of_SB_per_tile_width)**

Surface	8 bits		10 bits		Comments
	SB64	SB128	SB64	SB128	
Bitstream Decoder/~~Encode~~ Line Rowstore (BTDL)	2	4	2	4	**Decoder Only**
Spatial Motion Vector Line Rowstore (SMVL)	4	8	4	8	
Intra Prediction Line Rowstore (IPDL)	2	4	4	8	
Deblocker Filter Line Y Buffer (DFLY)	9	17	11	21	
Deblocker Filter Line U Buffe (DFLU)	3	4	3	5	
Deblocker Filter Line V Buffe (DFLV)	3	4	3	5	

The following rowstore requires extra CL allocation in addition to CL per SB.

To allocate the following: **Total CLs = (#CLs_per_SB * num_of_SB_per_tile_width) + #CLs_extra_per_surface**

Surface	#CLs per SB				#CLs extra per surface			
	8 bit		10 bit		8 bit		10 bit	
	SB64	SB128	SB64	SB128	SB64	SB128	SB64	SB128
CDEF Filter Line Buffer (CDEF)	8	16	10	20	1	1	2	2

The following tables indicate AV1 tile storage. These will NOT be stored in Internal Media Storage.

To allocate the following, use the following equations based on Tile Line Rowstore or Tile Column Rowstore:

Total Tile Line CLs = (#CLs_per_SB * num_of_SB_per_FRAME_width)

Total Tile Column CLs = (#CLs_per_SB * num_of_SB_per_FRAME_height)

[Programming suggestion: The largest tile width is 4096 in pixels. It is recommended to allocate the buffer based on 4096 tile width

and it can be reused for all tiles within the frame]

Surface	8 bit		10 bit		Comments
	SB64	SB128	SB64	SB128	
Bitstream Decode/Encode Tile Line Rowstore	2	4	2	4	**Decode/Encode**
Spatial Motion Vector Tile Line Rowstore	4	8	4	8	
Intra Prediction Tile Line Rowstore Tile Row	2	4	4	8	
Deblocker Filter Tile Line Y Buffer	9	17	11	21	
Deblocker Filter Tile Column Y Buffer	8	16	10	20	
Deblocker Filter Tile Line U Buffer	3	4	3	5	
Deblocker Filter Tile Column U Buffer	2	4	3	5	
Deblocker Filter Tile Line V Buffer	3	4	3	5	
Deblocker Filter Tile Column V Buffer	2	4	3	5	
CDEF Filter Top-Left Corner Buffer	**1 * num_Tile_Horz * num_Tile_Vert**				1 CL per tiles
CDEF Filter Meta Tile Line Buffer	**1 * num_Tile_Horz**				1 CL per horz

		tile
Loop Restoration Tile Line Y Buffer	**7 * num_Tile_Horz**	7 CL per horz tile
Loop Restoration Tile Line U Buffer	**5 * num_Tile_Horz**	5 CL per horz tile
Loop Restoration Tile Line V Buffer	**5 * num_Tile_Horz**	5 CL per horz tile

The following buffer requires extra CLs at the end of frame width/height. These will NOT be stored in Internal Media Storage.

To allocate the following, use the following equations based on Tile Line Rowstore or Tile Column Rowstore:

Total Tile Line CLs = (#CLs_per_SB * num_of_SB_per_FRAME_width) + #CLs_extra_per_surface

Total Tile Column CLs = (#CLs_per_SB * num_of_SB_per_FRAME_height) + #CLs_extra_per_surface

[Programming suggestion: The largest tile width is 4096 in pixels. It is recommended to allocate the buffer based on 4096 tile width

and it can be reused for all tiles within the frame]

Surface	**#CLs per SB**				**#CLs extra per surface**			
	8 bit		**10 bit**		**8 bit**		**10 bit**	
	SB64	**SB128**	**SB64**	**SB128**	**SB64**	**SB128**	**SB64**	**SB128**
CDEF Filter Tile Line Buffer	8	16	10	20	1	1	2	2
CDEF Filter Tile Column Buffer	8	16	10	20	1	1	2	2
CDEF Filter Meta Tile Column Buffer	1	1	1	1	0	0	0	0
Super-Res Tile Column Y Buffer	22	44	29	58	22	44	29	58
Super-Res Tile Column U Buffer	8	16	10	20	8	16	10	20
Super-Res Tile Column V Buffer	8	16	10	20	8	16	10	20
Loop Restoration Filter Tile Column Y Buffer	9	17	11	22	2	2	2	2
Loop Restoration Filter Tile Column U Buffer	5	9	6	12	1	1	1	1
Loop Restoration Filter Tile Column V Buffer	5	9	6	12	1	1	1	1
Loop Restoration Meta Tile Column Buffer	1	1	1	1	1	1	1	1

The following table indicates AV1 frame buffer (except pixel buffer).

Surface	**SB64**	**SB128**	**Comments**
CDF Tables Initialization Buffer	**242** CLs		Intra frame uses 183 CLs; inter frame uses 242 CLs
CDF Tables Backward Adaptation Buffer	**242** CLs		
AV1 Segment ID Read	**2** *	**8** *	

Buffer	Total_Num_SB64_in_Frame	Total_Num_SB128_in_Frame	
AV1 Segment ID Write Buffer	**2** * Total_Num_SB64_in_Frame	**8** * Total_Num_SB128_in_Frame	
Collocated Motion Vector Temporal Buffer	**4** * Total_Num_SB64_in_Frame	**16** * Total_Num_SB128_in_Frame	
Current Frame Motion Vector Write Buffer	**4** * Total_Num_SB64_in_Frame	**16** * Total_Num_SB128_in_Frame	

This section documents the Internal Media Storage Programming for AV1 decoder.

The following table is created for a maximum of 4k tile width.

Since AV1 has a restriction of maximum 4k tile width and each tile is programmed

per tile independently, only 4k tile programming is needed (unlike other codec)

			Address Programming (N/A means disable)							
Format	Bitdepth	TileSize	BTDL	SMVL	IPDL	DFLY	DFLU	DFLV	CDEF	
420	8/10 bit	<= 4k	0	128	384	640	1344	1536	1728	N/A

AVP Common Commands

This documents commands only for AVP codec decoder

Commands
AVP_REF_IDX_STATE
AVP_SEGMENT_STATE
AVP_BSD_OBJECT

AVP Pipe Common Commands

The AVP Pipe Common Commands specify the AVP Decoder pipeline level configuration.

Shared Commands
VD_CONTROL_STATE

AVP Commands
AVP_PIPE_MODE_SELECT
AVP_SURFACE_STATE
AVP_PIC_STATE
AVP_PIPE_BUF_ADDR_STATE
AVP_TILE_CODING
AVP_IND_OBJ_BASE_ADDR_STATE

Video Command Streamer (VCS)

The VCS (Video Command Streamer) unit primarily serves as the software programming interface between the O/S driver and the MFD Engine. It is responsible for fetching, decoding, and dispatching of data packets (Media Commands with the header DWord removed) to the front end interface module of MFX Engine.

Its logic functions include:

- MMIO register programming interface
- DMA action for fetching of execlists and ring data from memory
- Management of the Head pointer for the Ring Buffer
- Decode of ring data and sending it to the appropriate destination: AVC, VC1, or MPEG2 engine
- Handling of user interrupts
- Handling of ring context switch interrupt
- Flushing the MFX Engine
- Handle NOP

The register programming (RM) bus is a DWord interface bus that is driven by the Gx Command Streamer. The VCS unit only claims memory mapped I/O cycles that are targeted to its range of 0x4000 to 0x4FFFF. The Gx and MFX Engines use semaphore to synchronize their operations.

VCS operates completely independent of the Gx CS.

The simple sequence of events is as follows: a ring (say PRB0) is programmed by a memory-mapped register write cycle. The DMA inside VCS is kicked off. The DMA fetches commands from memory based on the starting address and head pointer. The DMA requests cache lines from memory (one cacheline CL at a time). There is guaranteed space in the DMA FIFO (16 CL deep) for data coming back from memory. The DMA control logic has copies of the head pointer and the tail pointer. The DMA increments the head pointer after making requests for ring commands. Once the DMA copy of the head pointer becomes equal to the tail pointer, the DMA stops requesting.

The parser starts executing once the DMA FIFO has valid commands. All the commands have a header DWord packet. Based on the encoding in the header packet, the command may be targeted towards AVC/VC1/MPEG2 engine or the command parser. After execution of every command, the actual head pointer is updated. The ring is considered empty when the head pointer becomes equal to the tail pointer.

Context Management

Video Engine Power Context

This section lists the power context image of Video Engine across generations.

Video Engine Power Context

Table below captures the data from VCS power context save/restored by PM. Address offset in the below table is relative to the starting location of VCS in the overall power context image managed by PM.

Address offsets in this table are relative to the starting location of VCS in the power context image managed by each engine. MMIO offset mentioned for the registers in the below table are offset from the units "MMIO Base Offset" mentiond in the table " Base Offset for all engines in the section Register Access and User Mode Privileges. For Example: VCS has MMIO Base Offset as "0x1C_0000". In the below table GFX_MODE register has 0x0029C as offset against it, actual MMIO Offset of GFX_MODE register for VCS is 0xx1C_029C and for VECS it would be 0x1C_829C.

VCS Power Context Image

Description	MMIO Offset	Unit	# of DW	Address Offset (PWR)	CSFE/CSBE
CSFE Power context without Display		VCS	192	**0**	**CSFE**

MI_BATCH_BUFFER_END		CSEND	1	**00C0**
NOOP		CSEND	127	**00C1**
			DW	320
			K Bytes	1.25

Video Command Formats

MFX Commands

The MFX (MFD for decode and MFC for encode) commands are used to program the multi-format codec engine attached to the Video Codec Command Parser. See the *MFD* and *MFC* chapters for a description of these commands.

MFX state commands support direct state model and indirect state model. Recommended usage of indirect state model is provided here (as a software usage guideline).

Pipeline Type (28:27)	Opcode (26:24)	SubopA (23:21)	SubopB (20:16)	Command	Chapter	Recommended Indirect State Pointer Map	Interruptable?

Watchdog Timer Registers

The following registers are defined as Watchdog Timer registers:

Register
PR_CTR_CTL - Watchdog Counter Control
PR_CTR_THRSH - Watchdog Counter Threshold

Logical Context Support

This section contains the registers for Logical Context Support.

Register
BB_STATE - Batch Buffer State Register
CXT_EL_OFFSET - Exec-List Context Offset
BB_START_ADDR - Batch Buffer Start Head Pointer Register
BB_START_ADDR_UDW - Batch Buffer Start Upper Head Pointer Register
BB_ADDR_DIFF - Batch Address Difference Register
BB_ADDR - Batch Buffer Head Pointer Register
SBB_ADDR - Second Level Batch Buffer Head Pointer Register
SBB_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Register
WAIT_FOR_RC6_EXIT - Control Register for Power Management
SBB_STATE - Second Level Batch Buffer State Register

Register
BB_OFFSET - Batch Offset Register
RING_BUFFER_HEAD_PREEMPT_REG - RING_BUFFER_HEAD_PREEMPT_REG
BB_PREEMPT_ADDR - Batch Buffer Head Pointer Preemption Register
BB_PREEMPT_ADDR_UDW - Batch Buffer Upper Head Pointer Preemption Register
SBB_PREEMPT_ADDR - Second Level Batch Buffer Head Pointer Preemption Register
SBB_PREEMPT_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Preemption Register
MI_PREDICATE_RESULT_1 - Predicate Rendering Data Result 1
MI_PREDICATE_RESULT_2 - Predicate Rendering Data Result 2
FORCE_TO_NONPRIV - FORCE_TO_NONPRIV
INDIRECT_CTX - Indirect Context Pointer
INDIRECT_CTX_OFFSET - Indirect Context Offset Pointer
BB_PER_CTX_PTR - Batch Buffer Per Context Pointer
SYNC_FLIP_STATUS - Wait For Event and Display Flip Flags Register
SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1
SYNC_FLIP_STATUS_2 - Wait For Event and Display Flip Flags Register 2

Mode Registers

The following are Mode Registers:

Mode Register
MI_MODE - Mode Register for Software Interface
INSTPM - Instruction Parser Mode Register
NOPID - NOP Identification Register
IDLEDLY - Idle Switch Delay
RESET_CTRL - Reset Control Register
PREEMPTION_HINT - Preemption Hint
PREEMPTION_HINT_UDW - Preemption Hint Upper DWord
SEMA_WAIT_POLL - Semaphore Polling Interval on Wait

Misc Register
HWS_PGA - Hardware Status Page Address Register

Registers in Media Engine

This topic describes the memory-mapped registers associated with the Memory Interface, including brief descriptions of their use. The functions performed by some of these registers are discussed in more detail in the Memory Interface Functions, Memory Interface Instructions, and Programming Environment chapters.

The registers detailed in this chapter are used across multiple projects and are extensions to previous projects. However, slight changes may be present in some registers (i.e., for features added or removed), or some registers may be removed entirely. These changes are clearly marked within this chapter.

Register
TIMESTAMP - Reported Timestamp Count
CTX_TIMESTAMP - Context Timestamp Count

Memory Interface Commands for Video Codec Engine

This chapter describes the formats of the "Memory Interface" commands, including brief descriptions of their use. The functions performed by these commands are discussed fully in the *Memory Interface Functions* Device Programming Environment chapter.

This chapter describes MI Commands for the Video Codec Engine.

The commands detailed in this chapter are used across product families. However, slight changes may be present in some commands (i.e., for features added or removed), or some commands may be removed entirely. Refer to the *Preface* chapter for details.

MI Commands
MI_BATCH_BUFFER_END
MI_CONDITIONAL_BATCH_BUFFER_END
MI_BATCH_BUFFER_START
MI_FLUSH_DW
MI_COPY_MEM_MEM
MI_LOAD_REGISTER_REG
MI_MATH
MI_NOOP
MI_REPORT_HEAD
MI_SEMAPHORE_SIGNAL
MI_SEMAPHORE_WAIT
MI_STORE_REGISTER_MEM
MI_STORE_DATA_IMM
MI_SUSPEND_FLUSH
MI_USER_INTERRUPT
MI_LOAD_REGISTER_MEM
MI_ATOMIC
MI_FORCE_WAKEUP

HCP

HCP HW Codec Pipeline Introduction

The HEVC/VP9 Codec Pipeline (HCP) is a fixed function hardware video codec responsible for decoding and encoding HEVC/VP9 (High Efficiency Video Coding) video streams.

Scope

The primary scope of the HCP BSpec document is to provide a description of the HCP commands processed by the Video Command Streamer (VCS). The secondary scope is to provide a description of the status registers on the Message Channel Interface to support encoding and decoding of the HEVC and VP9 video formats.

The BSpec sections include:

- Summary of Features
- Architecture Overview
- Commands
- Register Definitions

Acronyms and Applicable Standards

Summary of Features

The following sections define the general features of the HCP HW Decoder and Encoder pipeline, and the features specific to HEVC and VP9 decoding and encoding, respectively.

VP9 Decoder Features

• Support full-featured VP9 Profile 1 and part of Profile 2 (444 only), up to 8K.

• All headers (uncompressed and compressed header) are parsed and decoded outside the HCP HW pipeline. They are then fed to the HW through a set of HCP (with VP9 specific) state commands.

• Supports inner-loop decode part of the VP9 encoder implementation.

VP9 Encoder Features

- Supports ENC-PAK architecture
- Supports multiple pass BRC rate control operation flow
- Supports the VP9 Main Profile standard
- VP9 PAK Only mode is not supported.

HCP Hardware Pipeline Features

- Supports both decoder and encoder functions, setup on a per picture basis:
  - Hardware acceleration provides Ctb/CU level decode and encode.
  - No context switch is supported within a frame process.

- Supports Video Command Streamer (VCS):
  - Shared with MFX HW pipeline, and at any one time, only one pipeline (MFX or HCP) and one operation (decoding or encoding) can be active.
- Supports Message Channel Interface:

Feature
Supports Tile-YS and Tile-YF.
Supports Tile-Y Legacy.

- Supports NV12 video buffer plane:
  - Supports 4:2:0, 8-bit per pixel component (Y, Cb and Cr) video.
- Supports 8Kx8K frame size.

HEVC Decoder Features

- Supports full-featured HEVC Main Profile standard, up to Level 6.2.
- Supports the long format HW decoding interface:
  - All headers (SPS, PPS, Slice Header) are parsed and decoded outside the HCP HW pipeline. They are then fed to the HW through a set of HCP state commands.
- Supports inner-loop decode with hardware entry points for Encoder.
- Error detection/resiliency down to the Ctb/CU level.

All 41 HEVC profiles:

- Yellow colored profiles have explicit GUID assigned
- Pink colored profiles are subset of Yellow colored profiles, and do not have their own GUID.
- Grey colored profiles are not supported by Intel HW at all.

No.	Version	HEVC Profiles	Spec. Description	Intel HW Decoder
1	Base	Main	8b 4:2:0 only	
2	Base	Main 10	8/9/10b 4:2:0 only	
3	Base	Main Still Picture	8b 4:2:0, 1 frame only	
7	RExt	Main 12	8 to 12b 400/420	-Mono
8	RExt	Main 4:2:2 10	8/9/10b 400/420/422	-Mono

HEVC Encoder Features

- Supports ENC-PAK architecture
- Supports multiple pass BRC rate control operation flow
- Supports the HEVC Main Profile standard, with certain restrictions on the feature set and coding parameters, listed in the following table:

HEVC Encoder Features and Restrictions

Note that there is a difference between what PAK supported and what ENC supported. A feature/function that is supported in the PAK, does not necessary being supported by ENC and MediaSDK and the like.

Coding Tool	Support	Restriction	Comments
LCU Size	Yes (spec)		Support all 3 sizes: 16x16, 32x32, 64x64.
CU Size	Yes (spec)		Support 8x8, 16x16, 32x32, 64x64. Max 64 CU per LCU; min. CU size intel supported is 8x8 for all LCU size.
PU Partition	Yes (spec)		Support all inter symmetric (square) and asymmetric (non-square) PU partitioning, according to HEVC spec. PU Size for inter : Smallest allowed is 4x8 and 8x4, and they cannot be bidirectional. Inter 4x4 PU is not allowed in Main Profile.
TU QuadTree		Partial (intel) max depth is set to 3	Max depth is 3 (64x64 CU with 4x4 TU). Decoder supports this depth, but probably no need to search this for encode. Better to just split CU. HM common conditions set the max to 2 for both inter and intra. Intel Encoder only supports 2 levels of quad-tree. That is, max_transform_hierarchy_depth_inter/intra <= 2. Max num of TUs per CU is 16.
AMP	Yes (spec)		Asymmetric Motion Partition (rectangular PU partitioning - 2NxnU, 2NxnD, nLx2N or nRx2N). Available only for 64x64 to 16x16 CU.
AMVP	Yes (spec)		Adaptive/Advanced Motion Vector Prediction : spatial and PU-based temporal co-located MV candidates with scaling. Logic available from decoder. HW PAK is supporting temporal MV candidates.
Merge	Yes (spec)		Merge Skip and Regular Merge. Max. 5 MV Merge candidates (4 spatial + 1 temporal co-located) with scaling. Logic available from decoder. [merge_flag, merge_index, skip_flag]
Parallel Motion Merge		No (intel)	Tool for parallel decode of MVs. Since this isn't constrained by Main Profile, the decoder has to meet performance targets in the worst case anyway.
MC Interpolation Filter	Yes (spec)		1/4-pel Luma MV precision, 1/8-pel Chroma MV precision. 8-tap Luma filtering for both 1/2-pel and 1/4-pel locations (1-pass). 4-tap Chroma filtering. Use separable (first horizontal then vertical 1-D filtering) filter coefficients. Not all filter kernels are symmetrical and can map into simple arithmetic. It is a DCT-IF based filter. All operations are within 16-bit data.
Weighted Prediction	Yes (spec)		Free for PAK since decoder already has it.
Combined Reference Frame List		No (intel)	Combine List0 and List1 into a single list to remove uni-prediction signaling overhead.
Intra modes	Yes (spec)		33 directions and DC/Planar modes, with adaptive pre-filtering on reference pixels and boundary smoothing.

Coding Tool	Support	Restriction	Comments
IPCM (intra)		No (intel)	Can be disabled completely by SPS, or only allowed at certain CU sizes. No bit maximum on CUs in any profile/level (yet), so as of today there's no mandate to support this for encode.
Constrained Intra		No (intel)	Allow only intra neighboring blocks for current block intra-prediction. Enabling this is a coding loss and does not result in a performance improvement in HW designs.
2D DCT Transform	Yes (spec)		Square shape only; 32x32, 16x16, 8x8 and 4x4.
Transform Skip Evaluation		No (intel) ENC will estimate the use of transform skip	Significant coding gains for screen content (PowerPoint etc.). This tool is disabled in the common conditions but isn't explicitly disallowed by Main Profile. FQ is not bypass.
Sign bit hiding		No (intel)	Coding gain by removing one bypass bin per TU. Requires some smarts in the PAK.
Trellis		No (intel)	Trellis Quantization
SAO		No (intel)	Difficult to implement in single pass, performance impact in 2-pass or with previous frame search. Needs investigation. Decoder will support it.
Loop Filter across tiles/slices boundary		No (intel)	Can be disabled for tiles and or slices in SPS, so that filter across all tiles and slices boundaries. Main profile doesn't constrain.
Scaling List	Yes (spec)		This uses the default (or custom) qp adjustment on a per-frequency basis within a TU. Good coding improvement over flat scaling.
dQP		Partial (intel) Yes for LCU; No for CU	Being able to change QP per LCU or even up to once per 8x8 CU can lead to significant coding gains.
Chroma QP offset		No (intel)	No ROI.
Dependent slices		No (intel)	It is now part of Main Profile, but Intel will not support it. SW can perform the slice repackaging without re-encoding.
Tiles		No (intel)	Although in Main Profile, it results in coding loss and doesn't improve performance on HW. SW parallel processing (multithreaded) tool
Wavefront (aka WPP)		No (intel)	Latest Main Profile spec has included Wavefront. We got a feedback that this feature is highly desirable to support high performance multithreading HEVC decoder.
Lossless coding		No (intel)	Note: this is not the same as IPCM. Also details of this are in flux.
Interlaced Video		No (intel)	Only progressive video encoding is supported.
LM mode	No (spec)		Chroma-from-luma intra prediction (Linear Mode) is not allowed in Main Profile (yet).

Coding Tool	Support	Restriction	Comments
NSQT	No (spec)		Non square transform is not allowed in the Main Profile
ALF	No (spec)		Expensive and not in Main Profile currently. If decoder is going to support it, may consider for encoder as well.
Entropy slices	No (spec)		Not allowed in Main Profile, it is a SW parallel processing (multithreaded) tool.
Slice granularity != 0	No (spec)		Not allowed by Main Profile, and highly likely to be removed from the standard completely.

Architecture Overview

HCP HW pipeline is designed to support two codec standards: HEVC and VP9. It implements the complete decoder process, but does not handle header (sequence header, frame/picture header, slice header and tile header) parsing which is to be done by application/driver at software level. It also implements the bitstream coding, residual generation and frame reconstruction part of the encoding process (namely PAK), whereas the bit rate control, motion estimation and the block coding decision are done either in software and/or in a separate HW modules.

For decoder, both HEVC and VP9 are fully compliant to the standards, while for PAK, only a subset of coding tools are implemented.

The HCP can be programmed to function as either VP9 or HEVC at frame level at a time. The command sequence for each codec is frame based.

HEVC/VP9 Encoder

The HEVC/VP9 encoder architecture consists of 2 major HW components: VDENC and PAK. In addition, the HEVC architecture also supports a 3 HW components mode: Media ENC (EUs/Kernels+VME), and PAK. Media EUs/Kernels implement the ENC portion of the encoding process. It communicates with the VME to determine the best inter and intra coding modes for each block based on a set of cost functions and algorithms. It also responsible for setting up multiple encoding passes to meet the target coding efficiency. For both modes, the PAK is used to generate the final compressed bitstream on a per LCU basis with coding parameters received from the ENC. It also provides feedback information for BRC rate control purpose. As part of the PAK operation, it invokes the decoder in the reconstruction process.

HCP Command Summary

The HCP is configured for encoding or decoding through a set of batch commands defined in the following sections. The software driver builds a frame level workload using these commands and stores these workloads in graphics memory where they are fetched by the Video Command Streamer (VCS) and presented to the HCP for processing. The commands are processed by the Workload Parser within the HCP and the hardware is configured by the Workload Parser prior to each frame level encode or decode. A workload is defined as a set of commands necessary to encode or decode one frame.

The software driver is required to read the HCP disable fuse to determine if the HCP is enabled. If it is disabled, then the software driver must not enable HCP batch commands to be sent to the HCP or a hang event may occur. Only when the HCP is enabled through the fuse, should the batch commands be sent to the HCP.

Workload Command Model

DWord0 of each command is defined in HCP DWord0 Command Definition. The HCP is selected with the **Media Instruction Opcode "7h**" for all HCP Commands.

HCP DWord0 Command Definition

DWord	Bits	Description
0	31:29	**Command Type** = PARALLEL_VIDEO_PIPE = 3h
	28:27	**Pipeline Type** = 2h
	26:23	**Media Instruction Opcode = Codec/Engine Name** = HCP = 7h
	22:16	**Media Instruction Command** = <*see* HCP Media Instruction Commands (Opcode=7h)>
	15:12	**Reserved: MBZ**
	11:0	**Dword Length** (Excludes Dwords 0, 1) = <*command length*>

Each HCP command has assigned a media instruction command as defined in HCP Media Instruction Commands (Opcode=7h).

HCP Media Instruction Commands (Opcode=7h)

Media Instruction Command	Command DWord0 [22:16]	Mode	Scope
HCP_PIPE_MODE_SELECT	0h	Enc/Dec	Picture
HCP_SURFACE_STATE	1h	Enc/Dec	Picture
HCP_PIPE_BUF_ADDR_STATE	2h	Enc/Dec	Picture
HCP_IND_OBJ_BASE_ADDR_STATE	3h	Enc/Dec	Picture
HCP_QM_STATE	4h	Enc/Dec	Picture
HCP_FQM_STATE (encoder only)	5h	Enc	Picture
Reserved	8h-Fh		

Media Instruction Command	Command DWord0 [22:16]	Mode	Scope
HCP_PIC_STATE	10h	Enc/Dec	Picture
HCP_TILE_STATE	11h	Dec	Picture
HCP_REF_IDX_STATE	12h	Enc/Dec	Slice
HCP_WEIGHTOFFSET_STATE	13h	Enc/Dec	Slice
HCP_SLICE_STATE	14h	Enc/Dec	Slice
HCP_TILE_CODING	15h	Enc/Dec	Tile
Reserved	16h-1Fh		
HCP_BSD_OBJECT_STATE (decoder only)	20h	Dec	Slice
HCP_PAK_OBJECT (encoder only)	21h	Enc	LCU
HCP_INSERT_PAK_OBJECT (encoder only)	22h	Enc	Bitstream
Reserved	23h-2Fh		
HCP_VP9_PIC_STATE	30h	Dec	Picture
HCP_VP9_SEGMENT_STATE	32h	Dec	Picture
HCP_VP9_PAK_STATE	35h	Enc	LCU
HCP_VP9_RDOQ_STATE	3Ch	Enc	LCU
Reserved	3Dh-7Fh		

HCP Command Sequence Examples

VP9 Encoder Command Sequence

For a single frame encoding process the command sequence is listed below. There are no states saved between frame encoded in the HCP. There should be no other commands or context switch within a group of PAK OBJECT Commands. HCP and MFX share the same VCS, but there is no common encoding and decoding command that can be executed in both pipes, mi_flush and MMIO commands.

------ Per Frame Level Commands

HCP_PIPE_MODE_SELECT

HCP_SURFACE_STATE

HCP_PIPE_BUF_ADDR_STATE

HCP_IND_OBJ_BASE_ADDR_STATE

HCP_VP9_PIC_STATE

HCP_VP9_SEGMENT_STATE

HCP_VP9_QUANT_LOOKUP_TABLES

HCP_PAK_INSERT_OBJECT - if header present at the beginning of frame

------- A group of LCUs

HCP_PAK_OBJECT

...

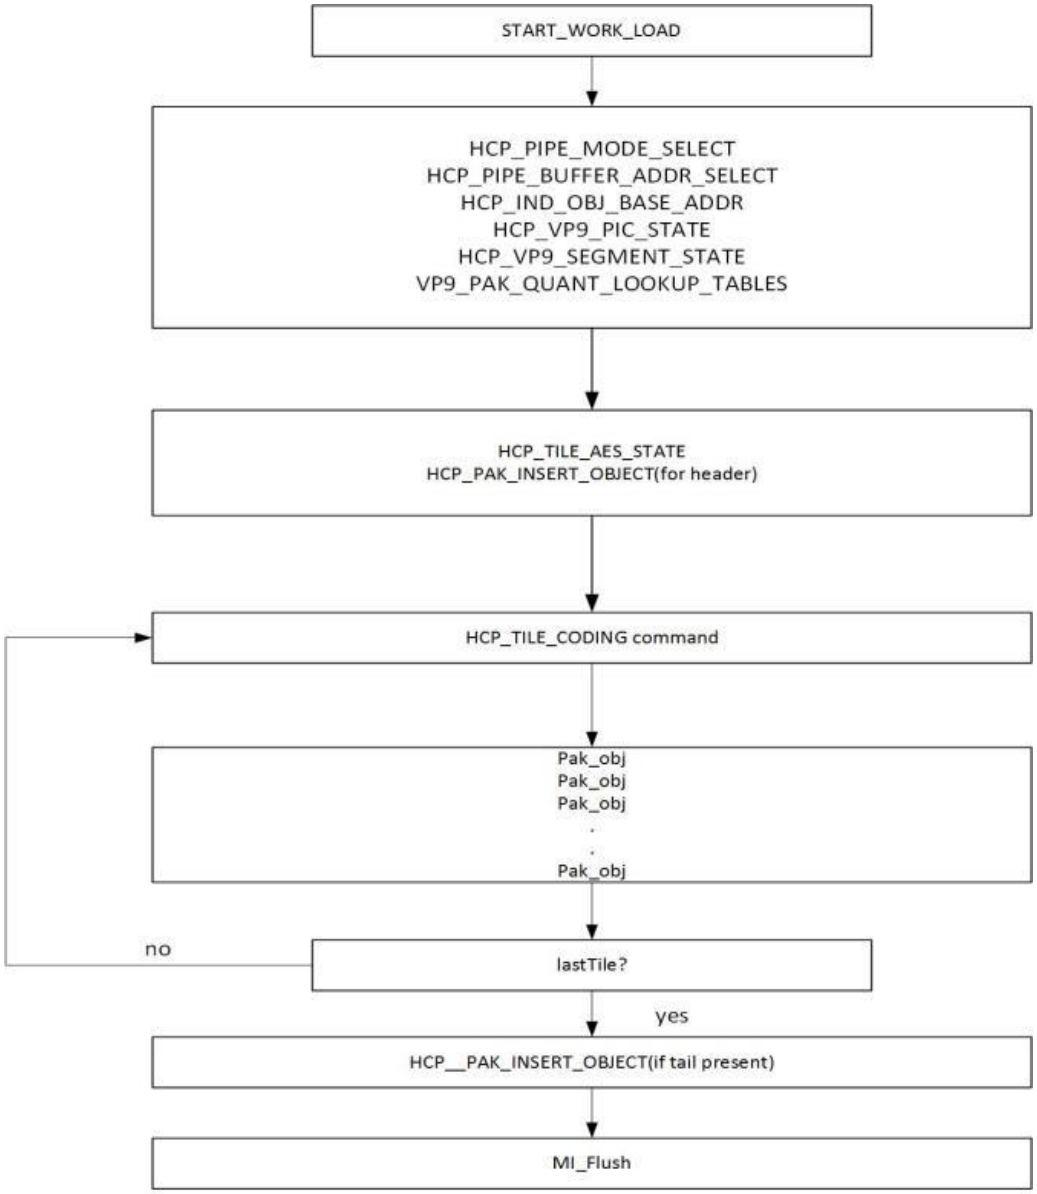
HCP_PAK_INSERT_OBJECT - if tail present at frame end

MI_FLUSH - when the frame is done

Command Sequence in Single Pipe Mode

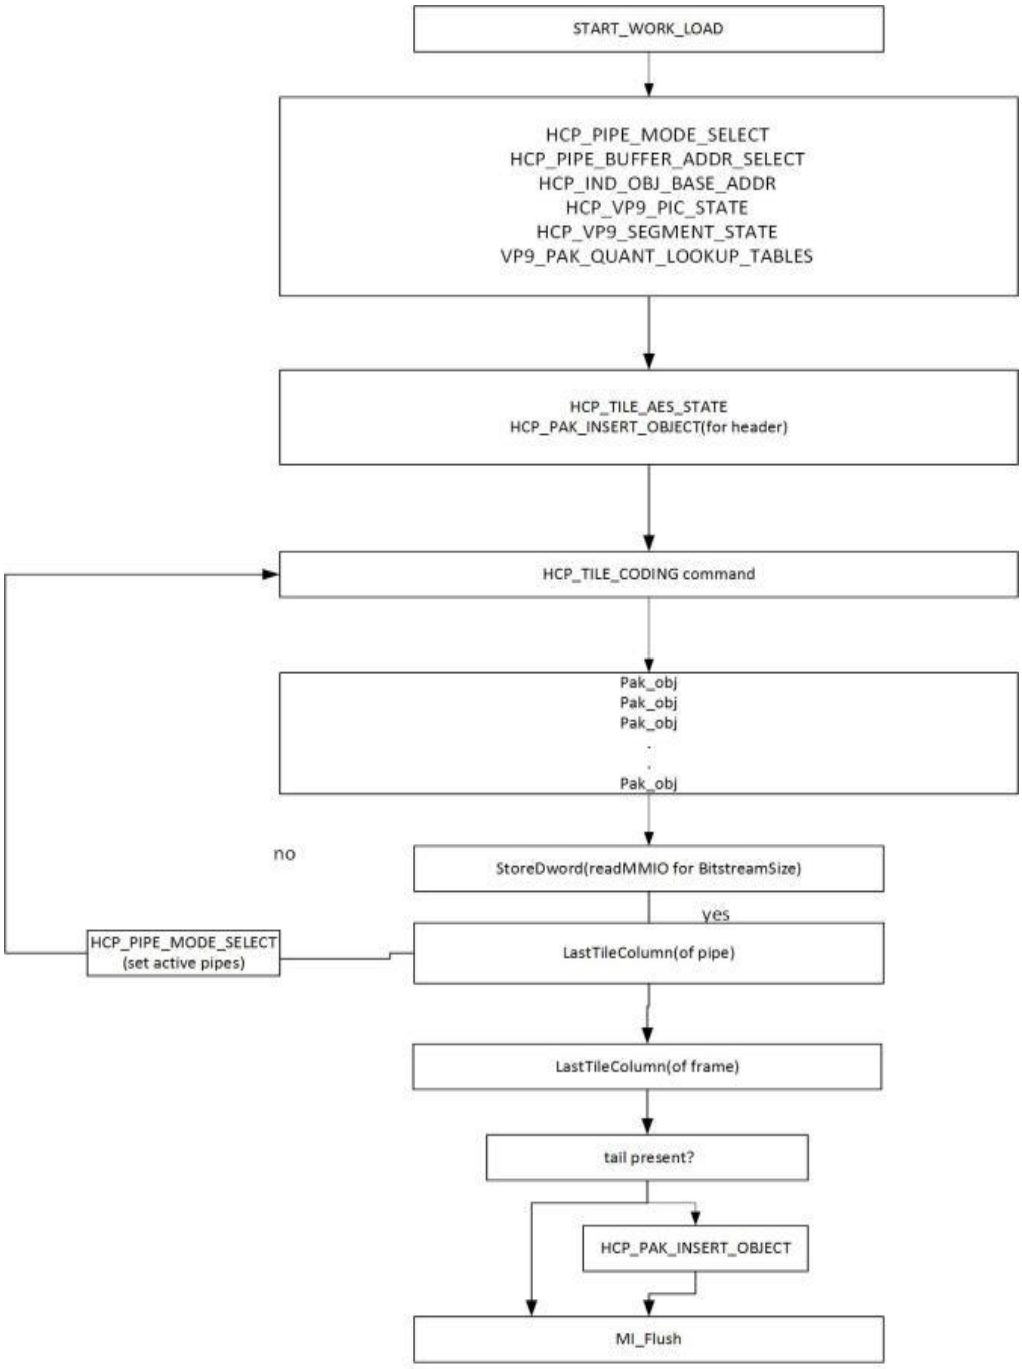
Command Sequences with Tile Support

Single Pipe Mode- Following flow chart shows the command sequence when encoding frame using a single pipe(VDbox).



VP9 encode command sequence for Single Pipe mode

Multiple Pipe Mode- When encoding a frame using multiple pipes, each pipe gets a single Tile Column or multiple Tile columns depending upon Number of tile columns to encode. Following flow chart shows commands sequence in a pipe (VDbox) when multiple pipes are used for encoding.



VP9 encode command sequence in Multiple Pipes mode

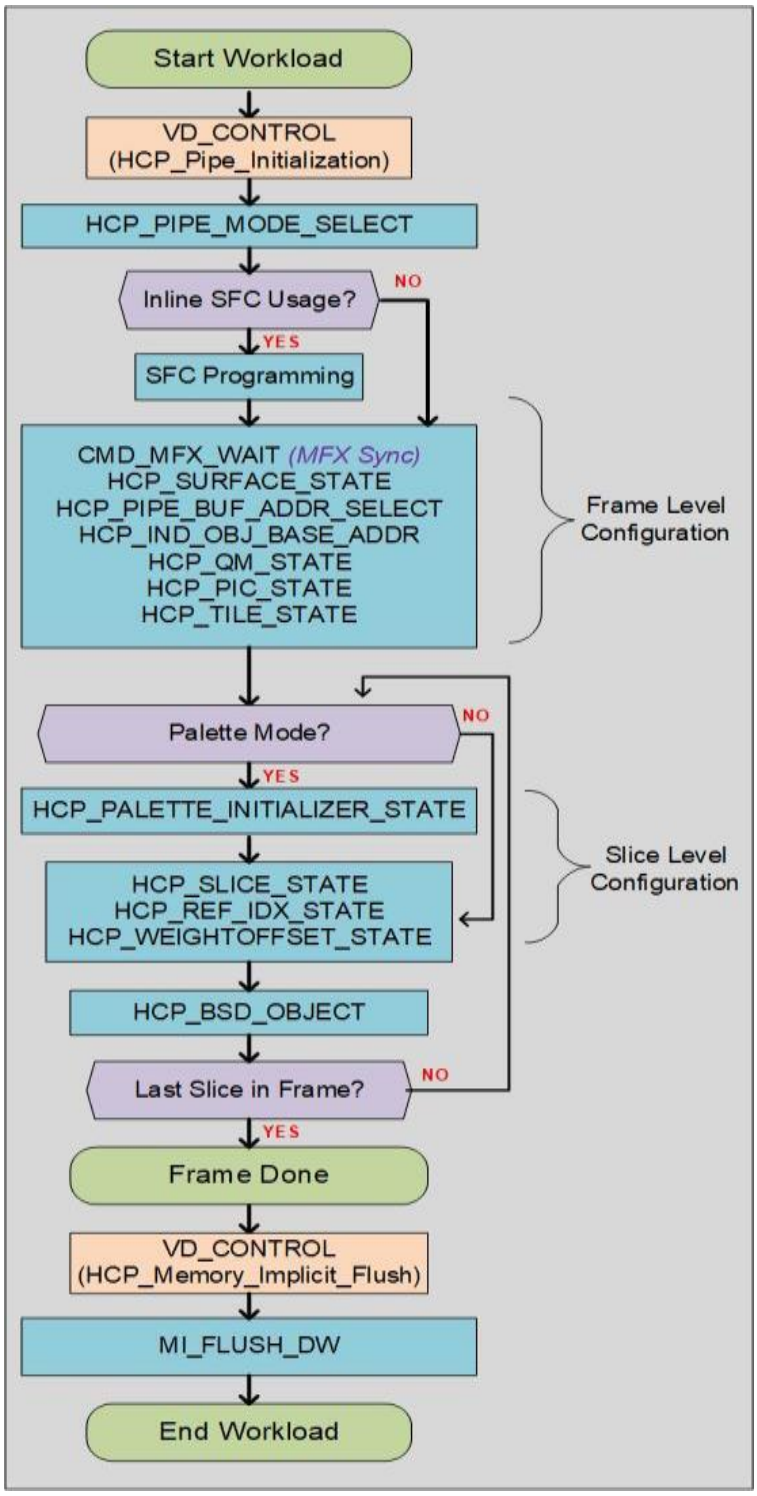
HCP Decoder Command Sequence

The long format workload for the HCP is based upon a single frame decode. There are no states saved between frame decodes in the HCP. Once the bit stream DMA is configured with the HCP_BSD_OBJECT command, and the bit stream is presented to the HCP, the frame decode will begin.

HCP Long Format Decode Workload Chart

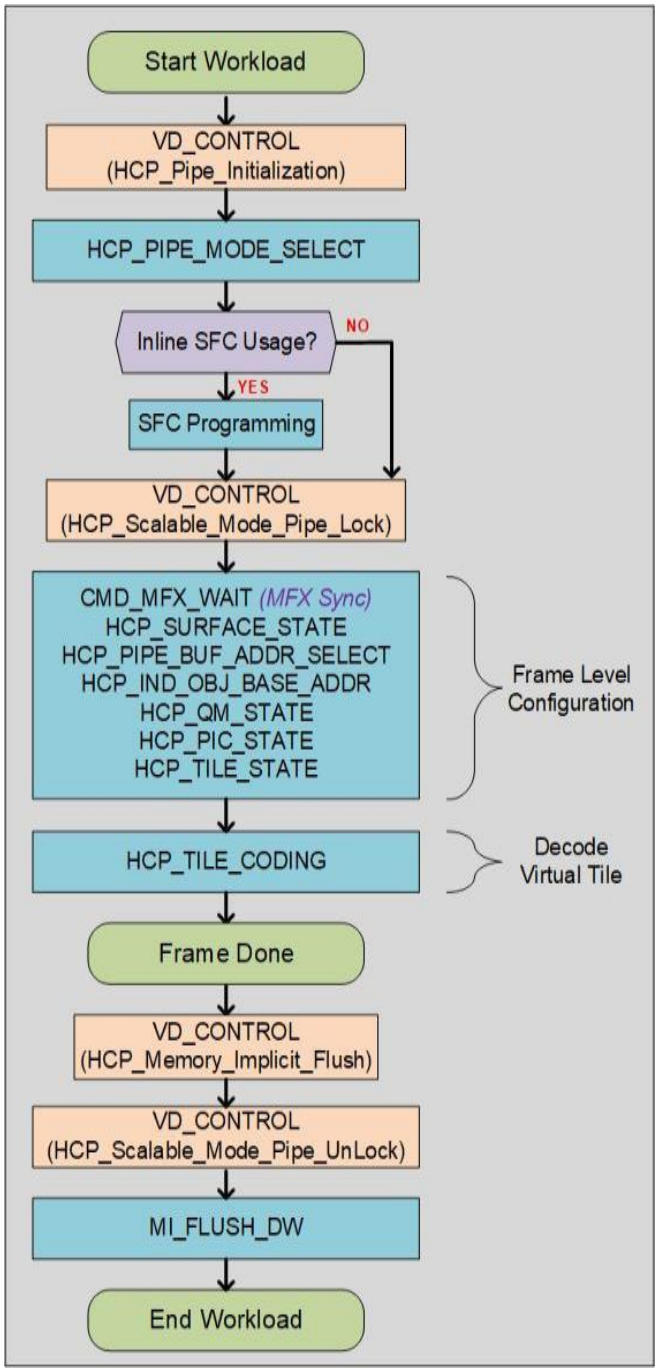
The following programming sequence will be used by single pipe decode (CABAC+BE reconstruction).

This is also used in scalable CABAC only decode mode.



HCP Scalabe Backend Only Workload Chart

The scalable decoder workload for the HCP backend pipe is based upon a single frame decode using multiple backend pipes. The frame is split into multple "virtual" vertical (column) tiles and they are processed by multple linked backend pipes. [NOTE: the above command sequence is still used for HCP CABAC decode and the decoded syntax elements are streamed to memory.]

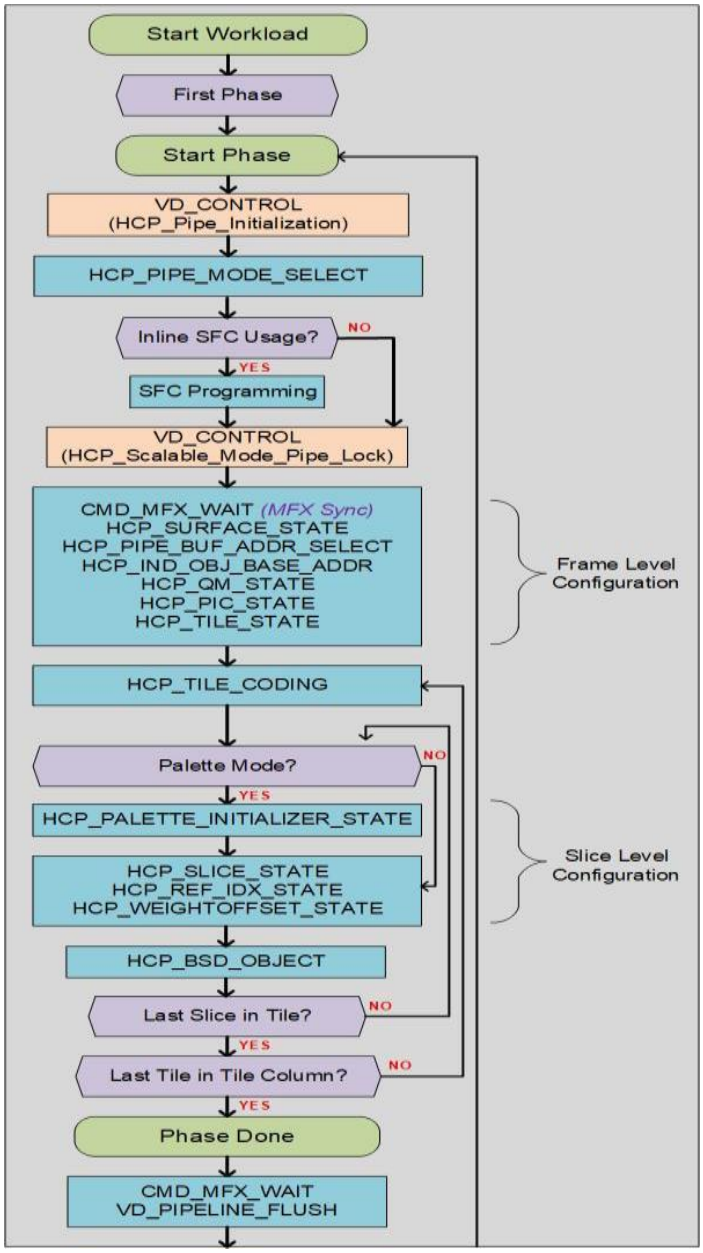


The scalable decoder with CABAC in real tiles allows frame with tiles to be decodes by multiple pipes. Each pipes will decode separate tile columns.

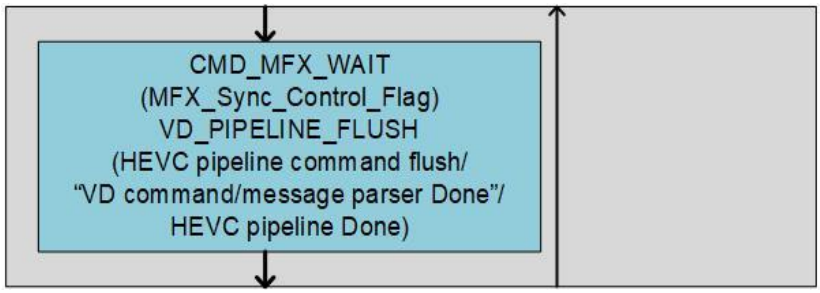
In this mode, the CABAC and BE will link and decode together. The following is the programming sequence.

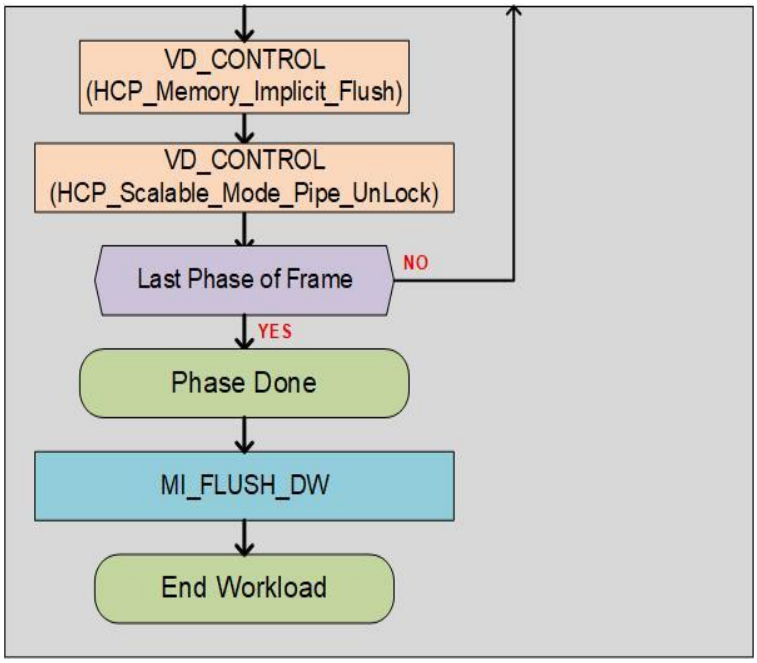
Also, the number of tiles may be greater than the number of pipes used to decode the frame. In this case, multiple phases will be introduced in the programming. For example, if N number of pipes are used to decode the frame. The first phases will decode 0 to (N-1) tile column. The next phase will decode N to (2N -1). This will continue till all the tile columns are processed.

[NOTE: The last phases may have fewer than N tile columns. In this case, only the needed pipes will be programmed and used.



This needs to be added between tiles.





HCP Encoder Command Sequence

For a single frame encoding process (w/o multiple slices per frame), the command sequence is listed below. There are no states saved between frame encoded in the HCP. There should be no other commands or context switch within a group of PAK OBJECT Commands, representing a complete slice. HCP and MFX share the same VCS, but there is no common encoding and decoding command that can be executed in both pipes, mi_flush and MMIO commands.

------ Per Frame Level Commands

HCP_PIPE_MODE_SELECT

HCP_SURFACE_STATE

HCP_PIPE_BUF_ADDR_STATE

HCP_IND_OBJ_BASE_ADDR_STATE

HCP_FQM_STATE - issue n number of times

HCP_QM_STATE - issue n number of times

HCP_PIC_STATE

------- Per Slice Level Commands (2 cases)

------- A Frame with only 1 Slice:

HCP_REF_IDX_STATE - set to provide L0 list for a P or B-Slice

HCP_REF_IDX_STATE - set to provide L1 list for a B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L0 of a P or B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L1 of a B-Slice

HCP_SLICE_STATE

HCP_PAK_INSERT_OBJECT - if header present at 1st slice start

    ------- A group of LCUs Per Slice

    HCP_PAK_OBJECT

    ...

HCP_PAK_INSERT_OBJECT - if tail present at frame end

MI_FLUSH - when the frame is done

------ A Frame with Multiple Slices:

HCP_REF_IDX_STATE - set to provide L0 list for a P or B-Slice

HCP_REF_IDX_STATE - set to provide L1 list for a B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L0 of a P or B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L1 of a B-Slice

HCP_SLICE_STATE

HCP_PAK_INSERT_OBJECT - if header present at 1st slice start of a frame

    HCP_PAK_OBJECT - a group of LCUs for a slice or a frame

    ...

HCP_PAK_INSERT_OBJECT - if tail present at slice or frame end

HCP_REF_IDX_STATE - set to provide L0 list for a P or B-Slice

HCP_REF_IDX_STATE - set to provide L1 list for a B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L0 of a P or B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L1 of a B-Slice

HCP_SLICE_STATE

HCP_PAK_INSERT_OBJECT - if header present at slice start

    HCP_PAK_OBJECT - a group of LCUs for a slice or a frame

...

HCP_PAK_INSERT_OBJECT - if tail present at last slice end (frame end)

MI_FLUSH - when the frame is done

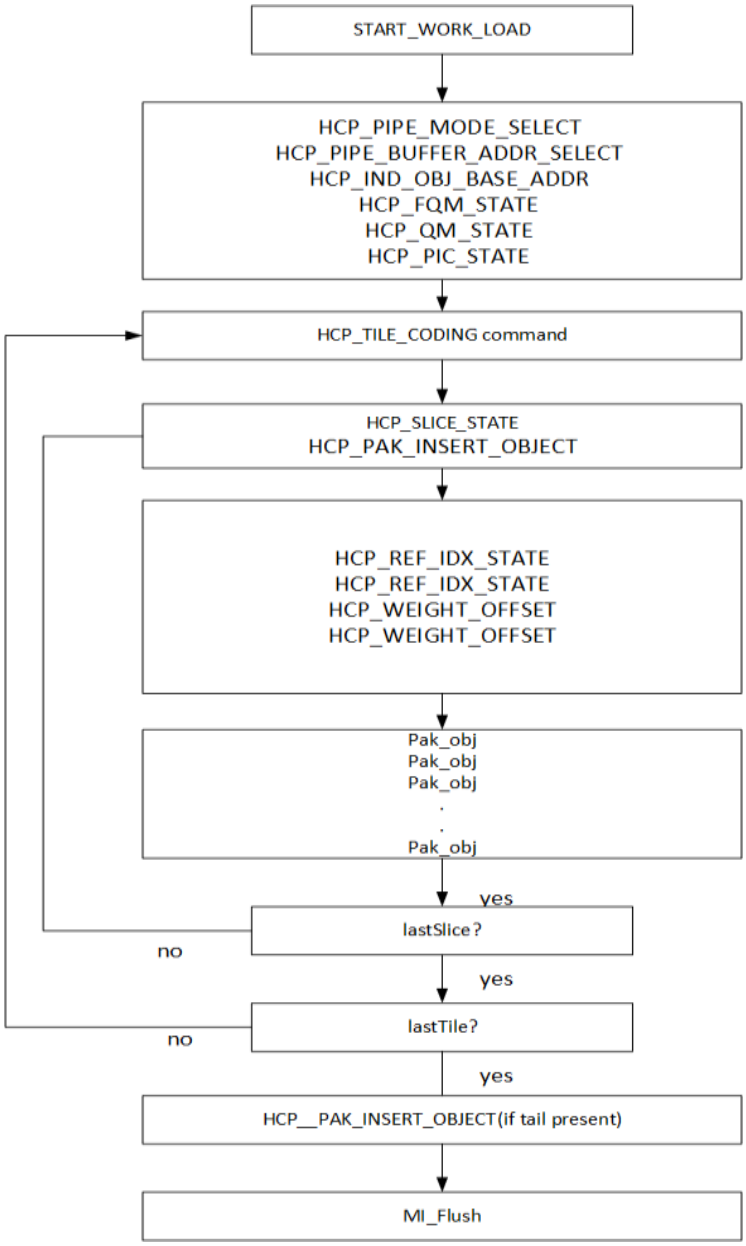
MFX_STITCH_OBJECT - a generic bitstream stitching command from MFX pipe

MI_FLUSH

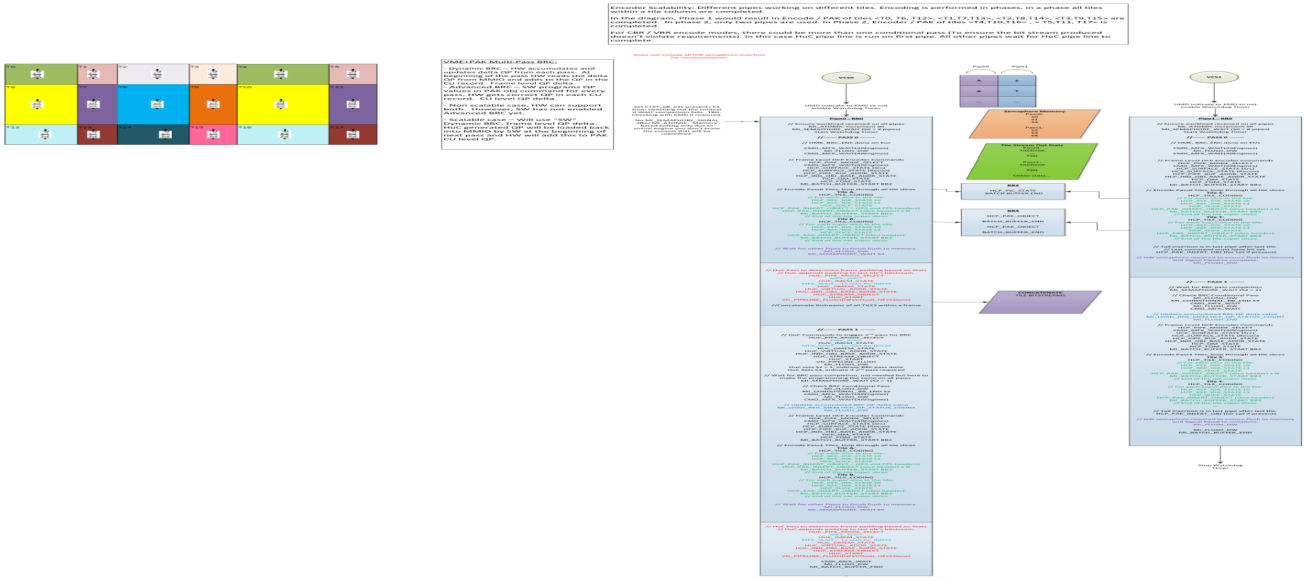
MI_FLUSH is not allowed between Slices. HEVC CABAC has simplified its operation from AVC. There is no longer a BSP_BUF_BASE_ADDR_STATE Command, as only a small local internal buffer is needed for BSP/BSE row store. THE HCP PAK_INSERT_OBJECT has been designed to support both inline and indirectly payload. Nevertheless, the MFX_STITCH_OBJECT command can still be used to stitch HEVC bitstreams together, and is run in the MFX pipe. No HEVC specific STITCH command is implemented. The SURFACE_STATE command for HEVC is redesigned and much simplified from that of MFX pipe.

Command Sequences with Tile Support

Single Pipe Mode- Following flow chart shows the command sequence when encoding frame using a single pipe(VDbox).



Multiple Pipe Mode- When encoding a frame using multiple pipes, each pipe gets a single Tile Column or multiple Tile columns depending upon Number of tile columns to encode. Following flow chart shows commands sequence in a pipe (VDbox) when multiple pipes are used for encoding.



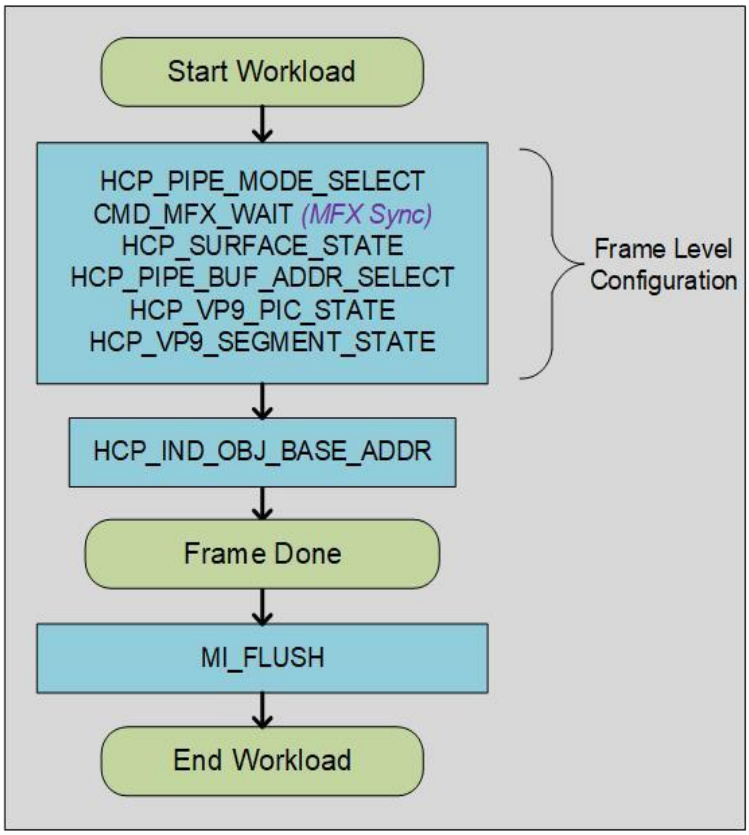
VP9 Decoder Command Sequence

VP9 decode programming is based upon a single frame decode. There are no states saved between frame decodes in the HCP. Once the bit stream DMA is configured with the HCP_IND_OBJ_BSD_OBJECT command, and the bit stream is presented to the HCP, the frame decode will begin.

VP9 Long Format Workflow Chart

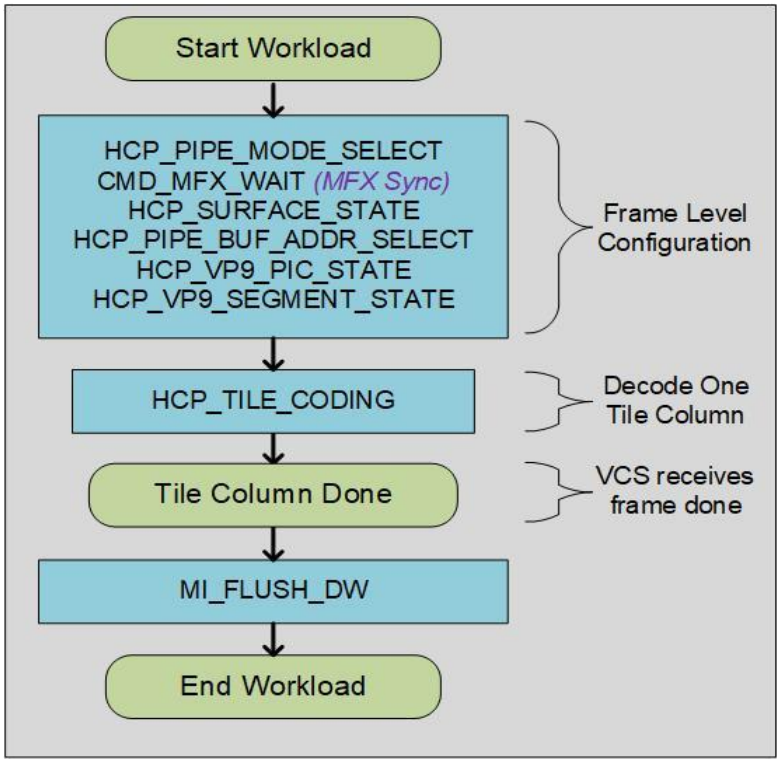
The following is the programming for single pipe decode.

The following programming also for scalable mode CABAC FE decode pass. There will be only one bitstream programming even if there are multiple tiles in the frame.



VP9 Scalable BE Only Workflow Chart

The following is the programming for scalable mode BE reconstruction pass (with multiple pipes). The following will be programmed on all the pipes.



Memory Address Attributes

This section defines the memory address attributes for the third DWord of the HCP command buffer address.

NOTE: The first DWord defines the lower address range and the second Dword defines the upper address range in the HCP command buffer address.

MemoryAddressAttributes

HCP Pipe Common Commands

The HCP Pipe Common Commands specify the HEVC Decoder pipeline level configuration.

Commands
HCP_PIPE_MODE_SELECT_VideoCS
HCP_SURFACE_STATE_VideoCS
HCP_PIPE_BUF_ADDR_STATE_VideoCS
HCP_IND_OBJ_BASE_ADDR_STATE_VideoCS
HCP_QM_STATE_VideoCS
HCP_FQM_STATE_VideoCS
HCP_TILE_CODING
VD_CONTROL_STATE

Buffer Size Requirements

HEVC Buffer Requirement

The following table indicates the buffer size in CLs per LCU. For memory allocation, the size will be the CLs per LCU * the number of LCU horizontally (if it is line) or vertically (if is column)

Mode	HEVC					
Lcu_y_size in pixels (64 for 64x64)						
Lcu_size is in number of 4x4 in the LCU per column (16 for 64x64)	8 bit			>8 bit		
	4:2:0	4:2:2	4:4:4	4:2:0	4:2:2	4:4:4

Motion Vector Temporal Buffer	num_height_in_SB) * 9	num_height_in_SB) * 9	num_height_in_SB) * 9	num_height_in_SB) * 9	num_height_in_SB) * 9	num_height_in_SB) * 9
VP9 Probability Buffer	32	32	32	32	32	32
VP9 Segment ID buffer (per frame)	(frame_width_in_sb64 * frame_height_in_sb64	(frame_width_in_sb64 * frame_height_in_sb64	(frame_width_in_sb64 * frame_height_in_sb64	(frame_width_in_sb64 * frame_height_in_sb64	(frame_width_in_sb64 * frame_height_in_sb64	(frame_width_in_sb64 * frame_height_in_sb64

Internal Media Rowstore table - If the internal Media Rowstore exists, driver should use the storage as the following table indicates.

This is for HEVC VMM setting. FrameWidth means frame width in picture width in decode/encode mode.

HEVC				Enable Setting					Addr Setting				
ArrayType	Bitdepth	LCU Size	FrameWidth	Meta/MV	Deblock	SAO	HSAO	VDEnc	DAT	DF	SAO	HSAO	VDEnc
420/422	8/10/12	16	<= 4096	Y	Y	Y	Y	N	0	256	1280	2048	N/A
		32/64	<= 4096	Y	Y	Y	Y	Y	0	256	1280	1792	1824
	8/10/12	16	4097 - 8192	Y	Y	N	N	N	0	512	N/A	N/A	N/A

HCP_PAK_OBJECT
HCP_PAK_INSERT_OBJECT
HCP_PALETTE_INITIALIZER_STATE

HCP and VP9 Commands

HCP_BSD_OBJECT (triggers HW start)

HCP_VP9_PAK_OBJECT

Tile Size and CU Stream-out Records

HEVC: Streamout0 cacheline is composed of 4 quarter cachelines, each containing information on CU skip flag, coding block flag for the TUs in a PU, residual/coefficient bit count for a PU, total bit count for CU, SB exceed limit flag. A typical streamout0 cacheline, therefore, has information on statistics for 4 PUs and Super Block exceed limit flag.

Pak pipeline streamout enable bit, set by HCP_PIPE_MODE_SELECT command, enables or disables the streamout.

Programming Note				
Context:		CU level statistics		
Level	**Field**	**Width**	**Cacheline**	**Comment**
PU	PU Skip Flag	1	qcacheline[0]	Packed in Quarter Cacheline in PU format
SB	SB exceed limit	1	qcacheline[1]	Packed in Quarter Cacheline in PU format (valid on last PU of SB)
	Reserved	14	qcacheline[15:2	Reserved
PU	TU CBF Y/U/V	48	qcacheline[63:16]	Packed in Quarter Cacheline in PU format
PU	PU Coefficient Bit Count (Only residual)	18	qcacheline[81:64]	Packed in Quarter Cacheline in PU format
PU	PU Bit Count (all PU Syntax)	18	qcacheline[113:96]	Packed in Quarter Cacheline in PU format
	Reserved	14	qcacheline[127:114]	Reserved

Programming Note

HEVC Streamout 1: Per Tile Quarter Cacheline

Level	Field	Width	Cacheline	Comment
Tile	Tile Bit Count (header + data + tail)	32	cacheline[31:0]	
	Reserved(MBZ)	32	cacheline[63:32]	
	TilePositionX[15:0]	16	cacheline[79:64]	
	TilePositionY[15:0]	16	cacheline[95:80]	
	Reserved(MBZ)	32	cacheline[127:96]	

VP9: CU statistics record (individual PUs per record down to 8x8 only)

Fields	Bits	
Skip	3:0	Indicates Skip flag Group 4 4x4s -> 4 bits
InterMode	11:4	InterMode: 0 NEARESTMV, 1 NEARMV, 2 ZEROMV, 3NEWMV Group 4 4x4s total 8 bits
Reserved	15:12	
NZ coeff count	28:16	Number of non-zero coeffs; sum of YUV, 13bits
Reserved	31:29	
NumBitsforCoeffs	47:32	Number of Bits for coefficients per block, 16bits
NumBitsforBlock	63:48	Number of Bits in block

Stream-in Probability Table

In Encoder mode, two sets of this table will be streamed out: one for the current frame probability update and one for future frame.

Alignment	New Offset	# Bytes	Description	Keyframe defaults	Inter frame defaults				Capture At DV_CNT		State counter EBB Address	Coefficient counter EBB Address

Stream-in formats for creating compressed header

The following memory surfaces are input to PAK for Compressed Header coding

i. Prob Diff Surface

In Probability Diff Surface, there are 1805 8-bit Probability Diffs. Each of them corresponding to a Probability Diff in Compressed Header syntax. Although, for a given compressed header, not all the Probability Diff would be coded (depends on update flag), Probability Diff Surface is fully populated with 1805 entries (1805*8 / 512 = 29 cachelines). The 1805 8-bit Probability Diffs are expected to follow Compressed Header syntax order and fully packed.

ii. Compressed Header Syntax Surface

Each of the Compressed header Coding element (described in (2)) is represented by a 4-bit field. These 4-bit fields follows Compressed Header Syntax. Each of the field has a valid, Bin_probDiff_select, Prob_select, Bin as described in the table below.

	Description
Valid	Set to 1 if this is a valid Bin OR ProbabilityDiff field to code; Set to 0 to skip coding this field
Bin_ProbDiff_select	Set to 1 if Current field is a Bin (corresponding Prob, Bin are indicated by next 2 bits); Set to 0 if Current field is Probability Diff (probability diff to be coded is located in probability surface - ReMap)
Prob_Select	If current field is Bin, set to 1 if prob is 252; set to 0 if prob is 128
Bin	if current field is Bin, this is Bin value to be encoded

Compressed Header Syntax Surface is a fixed length surface. For syntax that should not be coded, valid bit should be set to 0. Total length of Compressed Header syntax Surface has 4033 Coding elements (16132 bits in 32 cachelines):

1805 Prob Diff and Prob Update flag

4 is_coeff_updated flag (per 4x4, 8x8, 16x16, 32x32)

5 control fields (MIN (tx_mode, ALLOW_32x32), tx_mode == TX_MODE_SELECT, use_compound_pred, use_hybrid_pred)

Quant Scale and Filter Level Table

	Decode mode	Encode BRC first pass, or no BRC	Encode HW multi-pass BRC - Subsequent Passes
Determination of base qindex	N/A	Directly from PIC_STATE, base_qindex	`final_base_qindex = clip(0,255, base_qindex (from PIC_STATE) + accumulated delta from previous passes)`
Determination of inverse quant scale of each block	Directly from SEGMENT_STATE	`final_qindex = clip(0,255, clip(0, 255, base_qindex + // from PIC_STATE segment_q_delta) + // from SEGMENT_STATE chroma or AC delta // from PIC_STATE) iq_lookup_table[final_qindex];`	`final_qindex = clip(0,255, clip(0, 255, final_base_qindex + // from above segment_q_delta) + // from SEGMENT_STATE chroma or AC delta // from PIC_STATE) iq_lookup_table[final_qindex];`
Determination of forward quant scale and shift of each block	N/A	`fq_lookup_table[final_qindex];`	`fq_lookup_table[final_qindex];`
Determination of base filter level	N/A	Directly from PIC_STATE (filter_level) `final_base_filter_level = filter_level (from PIC_STATE)`	`final_base_filter_level = clip(0, 63, filter_level (from PIC_STATE) + accumulated delta from previous passes)`
Determination of final filter level of each block	Directly from SEGMENT_STATE	`mask = final_base_filter_level > 31 ? -2 : -1; final_filter_level = clip(0,63, clip(0,63, base_filter_level + // from PIC_STATE segment_lf_delta) + // from SEGMENT_STATE) (ref_delta & mask) + // from PIC_STATE (mode_delta & mask) // from PIC_STATE );`	`mask = final_base_filter_level > 31 ? -2 : -1; final_filter_level = clip(0,63, clip(0,63, final_base_filter_level + // from above segment_lf_delta) + // from SEGMENT_STATE) (ref_delta & mask) + // from PIC_STATE (mode_delta & mask) // from PIC_STATE );`

When SW writes the uncompressed header for an encoded frame, it must downshift the mode_delta and ref_delta by 1, if the final_base_filter_level > 31.

VP9 Allowed SB Size Encoder Only

The following table details the SB size allowed and the number of records per SB for the encoder.

Allowed SB Size - Encoder Only

VP9 SB Size Allowed	Number of Records per SB
64x64	64

Note: HW will support partial SBs within a frame boundary to a minimum CU8x8 granularity

HCP PAK Data Structure

The following documents HCP PAK Data Structure.

Tile Size and CU Stream-out Records

HEVC: Streamout0 cacheline is composed of 4 quarter cachelines, each containing information on CU skip flag, coding block flag for the TUs in a PU, residual/coefficient bit count for a PU, total bit count for CU, SB exceed limit flag. A typical streamout0 cacheline, therefore, has information on statistics for 4 PUs and Super Block exceed limit flag.

Pak pipeline streamout enable bit, set by HCP_PIPE_MODE_SELECT command, enables or disables the streamout.

Programming Note				
Context:		CU level statistics		
Level	**Field**	**Width**	**Cacheline**	**Comment**
PU	PU Skip Flag	1	qcacheline[0]	Packed in Quarter Cacheline in PU format
SB	SB exceed limit	1	qcacheline[1]	Packed in Quarter Cacheline in PU format (valid on last PU of SB)
	Reserved	14	qcacheline[15:2	Reserved
PU	TU CBF Y/U/V	48	qcacheline[63:16]	Packed in Quarter Cacheline in PU format
PU	PU Coefficient Bit Count (Only residual)	18	qcacheline[81:64]	Packed in Quarter Cacheline in PU format
PU	PU Bit Count (all PU Syntax)	18	qcacheline[113:96]	Packed in Quarter Cacheline in PU format
	Reserved	14	qcacheline[127:114]	Reserved

HEVC Streamout 1: Per Tile Quarter Cacheline

Level	Field	Width	Cacheline	Comment
Tile	Tile Bit Count (header + data + tail)	32	cacheline[31:0]	
	Reserved(MBZ)	32	cacheline[63:32]	
	TilePositionX[15:0]	16	cacheline[79:64]	
	TilePositionY[15:0]	16	cacheline[95:80]	
	Reserved(MBZ)	32	cacheline[127:96]	

VP9: CU statistics record (individual PUs per record down to 8x8 only)

Fields	Bits	
Skip	3:0	Indicates Skip flag Group 4 4x4s -> 4 bits
InterMode	11:4	InterMode: 0 NEARESTMV, 1 NEARMV, 2 ZEROMV, 3NEWMV Group 4 4x4s total 8 bits
Reserved	15:12	
NZ coeff count	28:16	Number of non-zero coeffs; sum of YUV, 13bits
Reserved	31:29	
NumBitsforCoeffs	47:32	Number of Bits for coefficients per block, 16bits
NumBitsforBlock	63:48	Number of Bits in block

Definition of the CU Record Structure- Encoder Only

The following table defines the CU record structure as indirect data to the PAK Object Command. Entries are DW based (4 bytes) and cache aligned. This memory surface is pointed to by the HCP Indirect CU Object Base Address in the HCP_IND_OBJ_BASE_ADDR_STATE Command.

CU Record Structure Definition

Intel restriction max 16 TU per CU, max 256 TUs in a CU.

Definition of the CU Record Structure for VME Interface - Encoder Only

DWord	Bitfield	Definition
R0.7	31	**CU_qp sign** Indicates sign bit for QP. Must be zero for 8bit mode
	30:24	**CU_qp** Note: HPM will set this to zero. This is a pass through for FBR and SRM. Kernel needs to populate this field before calling PAK. Magnitue of CU level QP. Valid range: 0 to 51 for 8bit mode -12 to 51 for 10bit mode -24 to 51 for 12bit mode

DWord	Bitfield	Definition
		QP can change at CU level Restriction: diff_cu_qp_delta_depth must be equal to either 0 or (lcu_size - min_cu_size)
	23	**zero_out_coefficients** 0: Do not force coefficients to zero for entire CU 1: Force coefficients to zero for entire CU *This bit must be zero in VDenc mode*
	23	**zero_out_coefficients_Y** 0: Do not force coefficients to zero in Luma block 1: Force coefficients to zero in Luma block
	22	IPCM_enable If IPCM is enabled, then entire CU is IPCM predicted. Both PU and TU sizes should be same as CU size. Cu_pred_mode is ignored when IPCM is enbled. 1- enable IPCM *0-disable IPCM* Note: Supports 8b only Note: Supports 8, 10 and 12bits. Note: HW ignores this bit for RhoDomain calculations so the statics will be slightly inaccurate.
	21	**Last CU of LCU Flag** Set to 1, if the current CU is the last one inside the current LCU (for VDENC only).
	20	**Modified Flag (should not be used by HW)**
	19:18	**InterPred_IDC_ MV1**
	17:16	**InterPred_IDC_ MV0**
	15	**cu_pred_mode**
	14:12	**CU_part_mode** **Note:** NxN CU_part_mode is used by RPM only in VME. It is used to generate predicted pixels using different prediction modes per 4x4 sub-block. i.e each 4x4 sub-block can have its own prediction mode. **Note:** 2NxN and N2XN intra is only valid for VP9. VP9 supports 32x16, 16x32, 16x8 and 8x16 Intra parititions. Luma Intra Mode indicates the intra prediction mode for 4x4_0. The additional prediction modes are overloaded on R0.6 [23:0] in this case.
	11	**CU_transquant_bypass_flag**
	10:8	**Chroma Intra Mode** 0: DM (use Luma mode, from block 0 if NxN) 1 : Reserved (supposedly to be defined for LM mode) 2: Planar

		allowed for 8x8 inter CU)

Note: In an 8x8 Inter CU NxN isn't allowed if the SPS parameter disable_inter_4x4 is 1. In Main profile currently this flag is always 1.

U.D, L and R (Up, Down, Left and Right)

n = 1/4 or 3/4 .

HEVC TU Partitioning for a Given CU

CU size	TU size	TU Depth	Max Depth=TU Depth+1	PAK supported TU sizes and corresponding number of TUs in CU
64x64	64x64	0	1	no 64x64 transform, so automatically breakdown into 4 32x32 TUs.
	32x32	1	2	number of TUs in CU = 4
	16x16	2	3	number of TUs in CU = 16
	8x8	3	4	this configuration is currently not supported.
	4x4	4	5	this configuration is currently not supported.
32x32	32x32	0	1	number of TUs in CU = 1
	16x16	1	2	number of TUs in CU = 4
	8x8	2	3	number of TUs in CU = 16
	4x4	3	4	this configuration is currently not supported.
16x16	16x16	0	1	number of TUs in CU = 1
	8x8	1	2	number of TUs in CU = 4
	4x4	2	3	number of TUs in CU = 16
8x8	8x8	0	1	number of TUs in CU = 1
	4x4	1	2	number of TUs in CU = 4

The actual level of partitioning is governed by

- MaxTUSize and MinTUSize in Pic State.
- max_transform_hierarchy_depth_inter <= 2 (intel restriction) DW4 bit 3:2 Pic State
- max_transform_hierarchy_depth_intra <= 2 (intel restriction) DW4 bit 1:0 Pic State

Allowed LCU Size - Encoder Only

The following table details the LCU size allowed and the number of records per LCU for the encoder.

LCU Size Allowed	Fixed Number of Records per LCU
64x64	64
32x32	16
16x16	4

Note: 0.5 CL per CU record in VME mode and 1 CL per CU record in extENC mode.

HEVC/VP9 PAK Frame Statistics

PAK outputs frame level statistics for RhoDomain, SSE, slice size conformance features and LCU statistics. The RhoDomain and Slice Size conformance parameters are exclusive only to HEVC. The SSE and LCU statistics are for both HEVC and VP9.

HEVC Frame Statistics

SliceSizeConformance

DWord	Bit	Description
0	31:17	**Reserved: MBZ**
	16	**Slice Overflow Occured** Format: Enable This field indicates that one or more slices in the current frame exceeded the Target size. When the actual slice size exceeds "Target slice size in Bytes", HW sets "Slice Overflow Occurred" bit in the PAK Frame Statistics.
	15:8	**MaxFrameQP** This parameter indicates the maximum CU QP in the frame. Format: U8 Valid Range is 0-63 for 10bit and 0-51 for 8bit hevc
	7:0	**MinFrameQP** This parameter indicates the minimum CU QP in the frame. Format: U8 Valid Range is 0-63 for 10bit and 0-51 for 8bit hevc
1	31:0	**Max Slice Size in Bytes** Format: U32 This parameter indicates the largest Slice in Bytes in the current frame.
2..3	31:0	**Reserved: MBZ**

VP9 Frame statistics

SSE Statistics

..33	63:48	**Reserved: MBZ**
	47:0	**Frame Luma SSE** MSB word of the Sum square Error statistics for the luma pixels in the current frame. The internal 4x4 subblock SSE is 24-bits. This is accumulated across the frame for all 4x4s and clamped to 48-bits. Format: U48
34..35	63:48	**Reserved: MBZ**
	47:0	**Frame Chroma Cb SSE** Sum square Error statistics for Cb pixels in the current frame. The internal 4x4 subblock SSE is 24-bits. This is accumulated across the frame for all 4x4s and clamped to 48-bits. Format: U48
36..37	63:48	**Reserved: MBZ**
	47:0	**Frame Chroma Cr SSE** Sum square Error statistics for Cr pixels in the current frame. The internal 4x4 subblock SSE is 24-bits. This is accumulated across the frame for all 4x4s and clamped to 48-bits. Format: U48
38	31:16	**Class0 Zone1 4X4 SUBBLKS SSE Count** This parameter indicates the count of the nu4x4 subblkser of macro-blocks in the current frame whose Sum square Error (SSE) met the Class0 Zone1 SSE threshold requirements. The output count is a multiple of 16. The value is internally » 4. Format: U16
	15:0	**Class0 Zone0 4X4 SUBBLKS SSE Count** This parameter indicates the count of the nu4x4 subblkser of macro-blocks in the current frame whose Sum square Error (SSE) met the Class0 Zone0 SSE threshold requirements. The output count is a multiple of 16. The value is internally » 4. Format: U16
39	31:16	**Max Class0 4X4 SUBBLKS SSE** The maximum macro-block sum square error for the Y+U+V pixels for the macro-blocks that were in Class 0.

		This is clamped to 16-bits. The internal 4x4 subblock SSE is 24-bits. It is » 4 before the threshold check for zone classification and Max 4x4 SSE clamping. Format: U16
	15:0	**Class0 Zone2 4X4 SUBBLKS SSE Count** This parameter indicates the count of the nu4x4 subblkser of macro-blocks in the current frame whose Sum square Error (SSE) met the Class0 Zone2 SSE threshold requirements. The output count is a multiple of 16. The value is internally » 4. Format: U16
40-55	31:0 (Each)	**SSE Statistics for Class1-8.** **Class1-8 Zone0 4X4 SUBBLKS SSE Count** **Class1-8 Zone0 4X4 SUBBLKS SSE Count** **Class1-8 Zone0 4X4 SUBBLKS SSE Count** **Max Class1-8 4X4 SUBBLKS SSE** SSE statistics for Class 1-8, see DW SSE Class 0 statistics for format.
56-63	31:0	**Reserved: MBZ**

HEVC Error Concealment

The HCP implements an error concealment policy, which is always enabled and cannot be disabled. The objective is that the HCP will always complete a frame/field workload by either decoding the bit stream normally until it finishes the workload or by concealing blocks until the slice or workload is completed. It should never be allowed to hang.

Error concealment, implemented by the HCP hardware, is configured for each slice in the HCP_BSD_OBJECT command. The following information in the HCP_BSD_OBJECT command is utilized for error concealment.

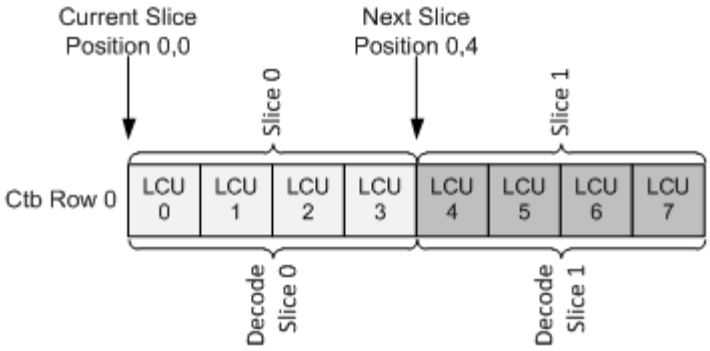
- **SliceStartCtbY, SliceStartCtbX:** The current slice position specified in Ctb coordinates.
- **NextSliceStartCtbY, NextSliceStartCtbX:** The next slice position specified in Ctb coordinates. If the current slice is the last slice in the picture, the next slice values are set to (0,0).
- **LastSliceofPic:** Indicates that the current slice is the last slice in the picture.
- **slice_type:** Indicates the picture type: I, P or B.

The host software will remove all extra slices in the picture. The HCP will not be given a workload that includes extra slices beyond the picture. The last slice in the picture will always be marked by the host software.

The host software will remove any overlapping slices in the picture. The HCP will not be given a workload that includes overlapping slices in the picture.

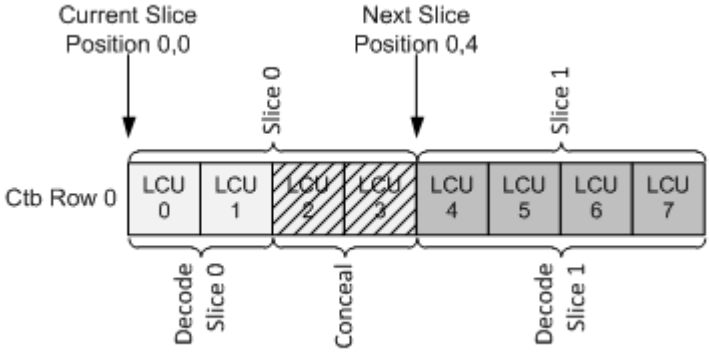
A HCP_BSD_OBJECT command will include the current slice position and the next slice position. For non-errored streams, it is guaranteed that the slice bit stream will be decoded by the HCP starting from the current slice position through to the Ctb (inclusive) adjacent to the Ctb indicated by the next slice position. HEVC Slice Decode for Non-errored Stream Cases illustrates the example of a non-errored stream decode starting with XXX.

HEVC Slice Decode for Non-errored Stream Cases



For error stream cases where the next slice position does not align itself with the last successfully decoded Ctb in the current slice, the HCP will conceal Ctbs from the last decoded Ctb in the current slice through to the last Ctb prior to the Ctb indicated by the next slice position. If the error occurs such that the current decoded Ctb cannot be decoded, the HCP will ensure that the current Ctb is written out by any means before writing out concealed Ctbs for the remaining Ctbs in the current slice. In the case of the last slice in a picture, the HCP will conceal Ctbs from the last decoded Ctb in the current slice through to the last Ctb position in the picture indicated by the resolution of the picture in the HCP_PICT_STATE command. HEVC Slice Decode for Missing Blocks in a Slice illustrates the case described.

HEVC Slice Decode for Missing Blocks in a Slice



Since the host software removes overlapping slices, the next slice position will never be equal to or less than the current slice position.

A concealed Ctb for an I-slice is constructed by the HCP specifying the Intra_Planar prediction mode for the Ctb.

A concealed Ctb for a P-slice is constructed by the HCP specifying the skip_flag.

A concealed Ctb for a B-slice is constructed by the HCP specifying the skip_flag.

HEVC Register Definitions

The Message Channel Interface is a read-only bus used to access the HCP status registers. All registers are 32 bits where reserved bits return a value of zero and subtractive-decode is used to return 0x0000 for all register holes. The Unit ID is 28h. For HCP, the address range is 0x0001E900h to 0001E9FFh.

HCP Encoder Register Read/Write

Register Name	Address	Tile-Based Engine OFF (Reads at FRAME boundary)	Tile-Based Engine ON (Reads at TILE ROW boundary)
HCP_BITSTREAM_BYTECOUNT_FRAME	8'hA0	Frame Byte Count per frame	Accumulated Frame Byte Count until current tile
HCP_BITSTREAM_BYTECOUNT_FRAME_NO_HDR	8'hA4	Frame Byte Count without header per frame	Accumulated Frame Byte Count without header until current tile
HCP_BITSTREAM_SE_BITCOUNT_FRAME	8'hA8	Syntax element bit count per frame	Accumulated Syntax element bit count until current tile
HCP_CABAC_BINCOUNT_FRAME	8'hAC	Bin count per frame	Accumulated Bin count until current tile
HCP_CABAC_INSERTION_COUNT	8'hB0	Cabac Zero Word insertion byte count per frame	Cabac Zero Word insertion byte count per frame. (only available at the last tile of the frame)
HCP_MIN_FRAME_PADDING_COUNT	8'hB4	Min Frame Padding byte count per frame	>Min Frame Padding byte count per frame. (only available at the last tile of the frame)
HCP_IMAGE_STATUS_MASK	8'hB8	Frame level Mask bits (BRC Min, BRC Max, LCU Max mask bits)	>Frame level Mask bits (BRC Min, BRC Max, LCU Max mask bits). Updates every HCP_PIC_STATE i.e. per tile
HCP_IMAGE_STATUS_CONTROL	8'hBC	Frame level Status Control bits. Cumulative Delta Qp, Frame Underflow/Overflow, LCU size exceed flag are reflected per frame level.	>Some bits are updated tile/frame level. Driver updates Cumulative Delta Qp at the start of every tile row. LCU size exceed flag updates every tile. Frame Underflow/Overflow updates only at last tile in a frame.
HCP_QP_STATUS_COUNT0	8'hC0	Min and Max Qp from HFQ per frame	Min and Max Qp per tile. (if read at TILE ROW then last TILE of the row's update will be available)
HCP_QP_STATUS_COUNT1	8'hC4	Cumulative Qp from HFQ per frame	Cumulative Qp per tile. (if read at TILE ROW then last TILE of

Register Name	Address	Tile-Based Engine OFF (Reads at FRAME boundary)	Tile-Based Engine ON (Reads at TILE ROW boundary)
			the row's update will be available)
HCP_SLICE_COUNT	8'hC8	Slice count per frame	Slice count in a frame until current tile
HCP_BITSTREAM_BYTECOUNT_TILE	8'hCC	Tile Byte Count. Since read happens at frame boundary, it will reflect tile size of the last tile in a frame	Current Tile Byte Count per tile. (if read at TILE ROW then last TILE of the row's update will be available)

Register Attributes Description

Host Register Attributes gives the defined register tags and their description.

Host Register Attributes

Tag	Name	Description
R/W	Read/Write	Bit is read and writeable.
R/SW	Read/Special Write	Bit is readable. Write is only allowed once after a reset.
RO	Read Only	Bit is only readable, but writes have no effects.
WO	Write Only	Bit is only writeable, reads return zeros.
RV	Reserved	Bit is reserved and not visible. Reads will return 0, and writes have no effect.
NA	Not Accessible	This bit is not accessible.

HCP Decoder Register Map

This documents all HEVC Decoder MMIO Registers.

HCP Decoder Register Descriptions

The HCP implements the following MMIO registers. A description of the register including its address and DWord descriptions are provided.

Registers
HCP Decode Status
HCP_CABAC_Status
HCP Last Position
HCP PMU Status
HCP Picture Checksum cIdx0
HCP Picture Checksum cIdx1

Registers
HCP Picture Checksum cIdx2

HCP Encoder Register Descriptions

Register
HCP_BIN_CT - HCP Frame BitStream BIN Count
HCP_BITSTREAM_BYTECOUNT_FRAME_NO_HEADER - Reported Bitstream Output Byte Count without header per Frame Register
HCP_BITSTREAMSE_BITCOUNT_FRAME - Reported Bitstream Output Bit Count for Syntax Elements Only
HCP_CABAC_BIN_COUNT_FRAME - Reported Bitstream Output CABAC Bin Count Register
HCP_CABAC_INSERTION_COUNT - Reported Bitstream Output CABAC Insertion Count
HCP_MINSIZE_PADDING_COUNT - Bitstream Output Minimal Size Padding Count Report Register
HCP_IMAGE_STATUS_CONTROL - HCP Image Status Control
HCP_QP_STATUS_COUNT - HCP Qp Status Count
HCP_UNIT_DONE - HCP Unit Done
HCP_IMAGE_STATUS_MASK - HCP Image Status Mask
HCP_SLICE_COUNT
Reported Bitstream Output Byte Count per Tile

Acronyms and Applicable Standards

Acronyms and Abbreviations

The table below defines acronyms and abbreviations used in this document.

Acronyms

Acronym	Meaning
AAC	Advanced Audio Coding -- part of the MPEG specification, AAC is the latest development in audio compression. It provides higher-quality audio reproduction than MPEG-1 Layer 3 (MP3), while requiring nearly 50% less data. It is defined in ISO/IEC 13818-7.
ADSL	Asymmetrical Digital Subscriber Line -- an asymmetrical DSL technology that takes advantage of the one-way nature of most multimedia communication, and provides much faster data rates for downstream (to the subscriber) then the upstream.
API	Application Programming Interface -- a set of routines used by an application program to request and carry out low-level services performed by the operating system.
ARGB	Alpha Red Green Blue -- color channel components.
ARIB	Association of Radio Industries and Business -- designated by the Ministry of Public Management, Home Affairs, Posts and Telecommunications (MPHPT) in Japan. ARIB members include broadcasters, radio equipment manufacturers, telecommunication operators, and related organizations.
ASP	Advanced Simple Profile - MPEG4-2

Acronym	Meaning
ATSC	ATSC Advanced Television Systems Committee - an organization in US that establishes and promotes technical standards for advanced television systems, such as digital television (DTV).
BDU	Bit-stream Data Unit
BIST	Built In Self Test
BPP	Bits Per Pixel
BSD	Byte Stream Decoder
CA, CAM	Conditional Access, Conditional Access Module - the removable descrambling module implemented in digital cable or satellite television system. The data flows through the module, which can have any proprietary scrambling algorithm implemented, yet maintaining system interface compatibility. The CAMs are usually provided by the operators in the TV network.
CPU	Central Processing Unit
DAA	Direct Access Arrangement
DAC	Digital-to-Analog Converter
DDA	Digital Difference Analyzer
DDS	Direct Digital Synthesizer
DPB	Decoded Picture Buffer. This buffer holds the decoded pictures for reference and for output along with the currently decoding picture. This differs from the DPB in the standard, which only holds the decoded pictures for reference.
DVB	Digital Video Broadcasting -- a set of open worldwide standards that define digital broadcasting using existing satellite, cable, and terrestrial infrastructures. It uses MPEG-2 specification as a universal foundation and expands it with DVB data structures and processes DVB-compliant digital broadcasting and equipment is widely available to consumers and is indicated with the DVB logo.
DVB-S	Satellite television DVB standards, based on QPSK and 8-DPSK modulation.
DVB-T	Terrestrial television DVB standards, based on 2k and 8k OFDM modulation.
DVD	Digital Versatile Disc
DVD-R	Recordable DVD. Since different disk formats are currently in use, including DVD-R,DVD+R, they are collectively mentioned as DVD-R in this document
DVI	Digital Visual Interface standard (EIA/CEA-861A). The standard defines a method for sending digital video signals over DVI and OpenLDI interface specifications. The standard is fully backward compatible with earlier DVI standards. New features include carrying auxiliary video information, such as aspect ratio and native video format information.
DVO	Digital Video Output - the parallel, low voltage signaling interface defined for Intel(R) video chipsets
DSL xDSL	Digital Subscriber Line - transmission of data over copper telephone lines capable of bringing high-bandwidth to subscribers. Many flavors of DSL are currently in use, which are collectively called xDSL throughout the document.
DSP	Digital Signal Processor
DST	Destination
DWord	A 32-bit word
ES	Elementary Streams -- the raw output of an encoder, containing only what is necessary for a

Acronym	Meaning
	decoder to approximate the original picture or audio.
FIFO	First in First Out
FIR	Finite Impulse Response
FPU	Floating Point Unit
FW	Firmware running on the decoder controller, as used in Volume 4 of the *Olo River Plus Silicon EAS*
IDR	Instantaneous Decoding Refresh
IEEE 1394 1394	IEEE 1394 or iLink* or FireWire* An IEEE electronics industry standard for connecting multimedia and computing Up to 63 devices can be attached to your PC via a single plug-and-socket connection.
IEEE 802.11 802.11	The Institute for Electronics and Electrical Engineers (IEEE) wireless network specification. 802.11g and 802.11a networks can transmit payload at the rates in excess 34Mbits/s and allow for the wireless transmission at distances from several dozen to several hundred feet indoors.
IF	Intermediate Frequency -- the fixed, relatively low-frequency carrier to which current programs are ported by the tuner.
GMCH	Graphics and Memory Control Hub -- a chip that connects the IA processor to memory and other components in PC.
HDD	Hard Disk Drive -- magnetic mass storage device used in media centers for audiovisual program recording.
HDMI	High Definition Multimedia Interface (HDMI). This interface is used between any audio/video source, such as a set-top box, DVD player, or A/V receiver, and an audio or video monitor, such as a DTV. HDMI supports standard, enhanced or high-definition video, plus multi-channel digital audio on a single cable. The format transmits all ATSC HDTV standards and supports eight-channel digital audio (at up to a 192kHz sampling rate), with bandwidth to spare for future enhancements.
HDTV	High-Definition Television -- HDTV specifically refers to the highest-resolution formats of the 18 total DTV formats, true HDTV is generally considered to be 1,080-line interlaced (1080i) or 720-line progressive (720p).
HSR	Hidden Surface Removal
HW	Hardware
I/F	Interface
IEEE	IEEE 32-bit Floating Point number format representation
ISP	Image Synthesis Processor -- A collective term to describe all components of the hidden surface removal operation within the PowerVR architecture.
LOD	Level Of Detail -- used in texturing calculations.
LSB	Least Significant Bit
LUT	Look-up table
MBAFF	Block Adaptive Field Frame mode
MFD	Multi-Format Decoder
MMU	Memory Management Unit
MMMC	Multi-port, Multi-channel Memory Controller
MSA	Intel Micro Signal Architecture -- microprocessor architecture combining the features of

Acronym	Meaning
	microcontroller and digital signal processor. MSA is used here as a synonym of the processor core used in Olo River Plus
MSB	Most Significant Bit
MPEG	Motion Picture Experts Group - Organization that develops standards for digital video and digital audio compression.
MPR	Inter Prediction Module
NAL	Network Abstraction Layer
NAL unit	Syntax structure in a H.264 stream
NTSC	National Television System Committee, North American 525-line analog broadcast TV standard.
NIM	Network Interface Module - the integrated tuner and digital demodulator in the (satellite) TV systems. The DVB NIMs output MPEG transport stream.
NOP	No operation
OEM	Original Equipment Manufacturer
OGL/OpenGL	Open GL application programming interface
PAL	Phase Alternation Line - TV standard used in Europe. PAL uses 625 lines per frame, a 25 frames per second update rate and YUV color encoding. The number of visible pixels for PAL video is 768 x 576.
PCI	Peripheral Component Interconnect bus, a bi-directional bus defined in PCI 2.x specification
PES	Packetized Elementary Streams -- packetized streams are the ES streams arranged in data packets with PES header starting every packet. The syntax of the ES and PES is defined in MPEG. See definition for ES.
PIP	Picture In Picture display mode
POD	Point of Deployment conditional access module -- the removable conditional access module defined in the OpenCable* specification in US.
PPS	Picture Parameter set
PTS	Presentation time stamp
PVR	Personal Video Recorder, also PDR or personal digital recorder -- an interactive TV-recording device that records programs in digital format and allows users to search for/record shows based on type (for instance all basketball games or all episodes of a particular program). Users can also pause, rewind, stop, or fast-forward live programs with only a small time lag.
PWL	Piece-wise Linear
PXD	Pixel Decoder Module
RF	Radio Frequency - usually, modulated carriers which can be directly received by the tuners of TVs or radio receivers
RISC	Reduced Instruction Set Computer
RHW	Reciprocal Homogenous W -- W is a 3-D coordinate representation like X Y Z
RSB	Row Store Buffer
RTL	Register Transfer Language/Level
SEI	Supplementary Enhancement Information

Acronym	Meaning
SIF	Semaphore Interface Module
SIMD	Single Instruction Multiple Data
SMPTE	Society of Motion Picture and Television Engineers
SOC	System on chip
SP	Simple Profile - MPEG4-2
SPS	Sequence Parameter set
SRC	Source
SDTV	Standard-Definition Television -- a digital television system that is similar to current analog TV standards in picture resolution and aspect ratio. Typical SDTV resolution is 480i or 480p.
STB	Set Top Box -- a device that effectively turns a television set into an interactive Internet device and/or allows the television to receive and decode digital television (DTV) broadcasts.
TA	Tile Accelerator
TS	MPEG-2 Transport Stream -- a sequence of 188-byte packets carrying the multi-program audiovisual data
TSP	Texture Shading Processor -- a collective term to describe all components of the texture, shading and pixel blending operations within the PowerVR architecture.
VCL	Video Coded Layer
VCXO	Voltage Controlled Crystal Oscillator
VGP/ VGP Lite	Vertex Geometry Processor
VLC	Variable length coded. This refers to the collection of coding techniques that are used in VC1, and include CABAC, CAVLC and Exp-Golomb.
VOL	Video Object Layer
VOP	Video Object Plane
WAN	Wide Area Network
WSS	Wide Screen Signaling
XDS	Extended Data Services -- data services sending data in line 21/283 of the analog NTSC TV signal
XSI	Intel(R) XScale(R) System Interconnect
X, Y, Z, W	3-D coordinate representations
YUV	YUV texture format, primarily for video formats

VP9 Register Definitions

This section describes the VP9 Register Definitions as follows:

- Register Attributes Description
- VP9 Register Map
- VP9 Encoder Register Descriptions

Register Attributes Description

Host Register Attributes gives the defined register tags and their description.

Host Register Attributes

Tag	Name	Description
R/W	Read/Write	Bit is read and writeable.
R/SW	Read/Special Write	Bit is readable. Write is only allowed once after a reset.
RO	Read Only	Bit is only readable, but writes have no effects.
WO	Write Only	Bit is only writeable, reads return zeroes.
RV	Reserved	Bit is reserved and not visible. Reads will return 0, and writes have no effect.
NA	Not Accessible	This bit is not accessible.

VP9 Encoder Register Descriptions

HCP_IMAGE_STATUS_MASK - HCP Image Status Mask

HCP_IMAGE_STATUS_CONTROL - HCP Image Status Control

HCP_UNIT_DONE - HCP Unit Done

MFX Pipe

MFC_AVC_PAK_OBJECT Command

PAK Object Inline Data Description

The Inline Data includes all the required MB encoding states, constitute part of the Slice Data syntax elements, MB Header syntax elements and their derivatives. It provides information for the following operations:

1. Forward and Inverse Transform
2. Forward and Inverse Quantization
3. Advanced Rate Control (QRC)
4. MB Parameter Construction (MPC)
5. CABAC/CAVLC encoding
6. Bit stream packing
7. Intra and inter-Prediction decoding loop
8. Internal error handling

These state/parameter values may subject to change on a per-MB basis, and must be provided in each MFC_AVC_PAK_OBJECT command. The values set for these variables are retained internally, until they are reset by hardware Asynchronous Reset or changed by the next MFC_AVC_PAK_OBJECT command.

The inline data has been designed to match the DXVA 2.0, with the exception of the starting byte (DW0:0-7) and the ending dword (DW7:0-31).

The Deblocker Filter Control flags (FilterInternalEdgesFlag, FilterTopMbEdgeFlag and FilterLeftMbEdgesFlag) are generated by H/W, which are depending on MbaffFrameFlag, CurrMbAddr, PicWidthInMbs and disable_deblocking_filter_idc states.

Current MB [x,y] address is not sent, it is assumed that the H/W will keep track of the MB count and current MB position internally.

DWord	Bit	Description
3	31	**ExtendedForm** This field specifies that **LumaIntraMode** and **RefPicSelect** are fully replicated in 4x4 and 8x8 sub-blocks respectively. This non-DXVA form is used for optimal kernel performance.
	30	Reserved: MBZ
	29:24	Reserved
	23	Reserved : MBZ (reserved for future use as ExternalMvBufFlag)
	22:20	MvFormat (Motion Vector Size). This field specifies the size and format of the output motion vectors. This field is reserved (MBZ) when the IntraMbFlag = 1. The valid encodings are: 000 = 0: No motion vector 100 = 8MV: Four 8x8 motion vector pairs 110 = 32MV: 16 4x4 motion vector pairs Others are reserved. (The following encodings are intended for future usages: 001 = 1MV: one 16x16 motion vector 010 = 2MV: One 16x16 motion vector pair 011 = 4MV: Four 8x8 motion vectors 101 = 16MV: 16 4x4 motion vectors 111 = Packed, number of MVs is given by PackedMvNum.)
	19	CbpDcY. This field specifies if the Luma DC sub-block is coded. Setting it to 0 will force PAK to zero out the Luma sub-block. Otherwise, whether the sub-block is coded will be determined by the quantization process. 1 – the 4x4 DC-only Luma sub-block of the Intra16x16 coded MB is present; it is still possible that all DC coefficients are zero.

DWord	Bit	Description
		0 – no 4x4 DC-only Luma sub-block is present; either not in Intra16x16 MB mode or all DC coefficients are zero.
	18	CbpDcU. This field specifies if the Chroma Cb DC sub-block is coded. Setting it to 0 will force PAK to zero out the Luma sub-block. Otherwise, whether the sub-block is coded will be determined by the quantization process. 1 – the 2x2 DC-only Chroma Cb sub-block of all coded MB (any type) is present; it is still possible that all DC coefficients are zero. 0 – no 2x2 DC-only Chroma Cb sub-block is present; all DC coefficients are zero.
	17	CbpDcV. This field specifies if the Chroma Cb DC sub-block is coded. Setting it to 0 will force PAK to zero out the Luma sub-block. Otherwise, whether the sub-block is coded will be determined by the quantization process. 1 – the 2x2 DC-only Chroma Cr sub-block of all coded MB (any type) is present; it is still possible that all DC coefficients are zero. 0 – no 2x2 DC-only Chroma Cr sub-block is present; all DC coefficients are zero.
	16	Reserved: MBZ (reserved for future use as ExternalResidBufFlag for turbo mode)
	15	Transform8x8Flag This field indicates that 8x8 transform is used for the macroblock. When it is set to 0, the current MB uses 4x4 transform. When it is set to 1, the current MB uses 8x8 transform. The transform_size_8x8_flag syntax element, if present in the output bitstream, is the same as this field. However, whether transform_szie_8x8_flag is present or not in the output bitstream depends on several other conditions. This field is only allowed to be set to 1 for two conditions: It must be 1 if IntraMbFlag = INTRA and IntraMbMode = INTRA_8x8 It may be 1 if IntraMbFlag = INTER and there is no sub partition size less than 8x8 Otherwise, this field must be set to 0. 0: 4x4 integer transform 1: 8x8 integer transform
	14	FieldMbFlag This field specifies the field polarity of the current macroblock, as the mb_field_decoding_flag syntax element in AVC spec. This field specifies whether current macroblock is coded as a field or frame macroblock in MBAFF mode. It is exactly the same as FIELD_PIC_FLAG syntax element in non-MBAFF mode.

DWord	Bit	Description
		0 = Frame macroblock 1 = Field macroblock
	13	IntraMbFlag This field specifies whether the current macroblock is an Intra (I) macroblock. I_PCM is considered as Intra MB. For I-picture MB (IntraPicFlag =1), this field must be set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes). 0: INTER (inter macroblock) 1: INTRA (intra macroblock)
	12:8	MbType5Bits This field is encoded to match with the best macroblock mode determined as described in the next section. It follows an unified encoding for inter and intra macroblocks according to AVC Spec.
	7	FieldMbPolarityFlag This field indicates the field polarity of the current macroblock. Within an MbAff frame picture, this field may be different per macroblock and is set to 1 only for the second macroblock in a MbAff pair if FieldMbFlag is set. Otherwise, it is set to 0. Within a field picture, this field is set to 1 if the current picture is the bottom field picture. Otherwise, it is set to 0. It is a constant for the whole field picture. This field is reserved and MBZ for a progressive frame picture. 0 = Current macroblock is a field macroblock from the top field 1 = Current macroblock is a field macroblock from the bottom field Programming Note: Here bits [26:24] (MbAffFieldFlag and FiedlMbPolarityFlag) match with bits [10:8] of the Media Block Read message descriptor, simplifying the programming for message generation, as when MbAffFieldFlag is “1”, kernels need to override the original “frame” surface state set for MBAFF frame picture.
	6	Reserved: MBZ
	5:4	IntraMbMode This field is provided to carry information partially overlapped with MbType. This field is only valid if IntraMbFlag = INTRA, otherwise, it is ignored by hardware..
	3	Reserved: MBZ
	2	SkipMbFlag By setting it to 1, this field forces an inter macroblock to be encoded as a skipped macroblock. It is equivalent to mb_skip_flag in AVS spec, indicating that a macroblock is inferred as a P_Skip (or

DWord	Bit	Description
		B_Skip) in a P Slice (or B Slice). Hardware honors input MVs for motion prediction and forces CBP to zero. By setting it to 0, an inter macroblock will be coded as a normal inter macroblock. The macroblock may still be coded as a skipped macroblock, according to the macroblock type conversion rules described in the later sub sections. This field can only be set to 1 for certain values of MbType. See details later. This field is only valid for an inter macroblock. Hardware ignores this field for an intra macroblock. 0 = not a skipped macroblock 1 = is coded as a skipped macroblock
	1:0	InterMbMode This field is provided to carry redundant information as that encoded in MbType. This field is only valid if IntraMbFlag =0, otherwise, it is ignored by hardware.
4	31:24	Reserved for future MbYCnt expansion.
	23:16	MbYCnt (Vertical Origin). This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
	15:8	Reserved for future MbXCnt expansion.
	7:0	MbXCnt (Horizontal Origin). This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
5	31:24	Reserved for future CbpAcUV exopansion for 4.2.2. and 4.4.4 For 4.2.2, [23:16] for U(Cb), and [31:24] for C(Cr). For 4.4.4, the field [31:16] is interpreted as CbpAdJ|CbpAcV for 16 sub-blocks.
	31:16	Cbp4x4V (Coded Block Pattern Cr) Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cr sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpCr bit assignment is cbpCr bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding).

DWord	Bit	Description
		For monochrome, this field is ignored. For 4.2.2, [23:16] for U(Cb), and [31:24] ignored. For 4.4.4, the definition is the same as for luma component: 1bit per 4x4 block.
	23:20	CbpAcV (Coded Block Pattern Cr) Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cr sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpCr bit assignment is cbpCr bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored.
	19:16	Cbp4x4U (Coded Block Pattern Cb) Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cb sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpCb bit assignment is cbpCb bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored.
	15:0	Cbp4x4Y[bit 15:0] (Coded Block Pattern Y) For 4x4 sub-block (when Transform8x8flag = 0 or in intra16x16) : 16-bit cbp, one bit for each 4x4 Luma sub-block (not including the DC 4x4 Luma block in intra16x16) in a MB. The 4x4 Luma sub-blocks are numbered as blk0 1 4 5 bit15 14 11 10 blk2 3 6 7 bit13 12 9 8 blk8 9 12 13 bit7 6 3 2

DWord	Bit	Description
		blk10 11 14 15 bit5 4 1 0 The cbpY bit assignment is cbpY bit [15 - X] for sub-block_num X. For 8x8 block (when Transform8x8flag = 1) Only the lower 4 bits [3:0] are valid; the remaining upper bits [15:4] are ignored. The 8x8 Luma blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpY bit assignment is cbpY bit [3 - X] for block_num X. 0 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding).
	15:0	Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cb sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpCb bit assignment is cbpCb bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored. For 4.2.2, [7:0] for U(Cb), and [15:8] ignored. For 4.4.4, the definition is the same as for luma component: 1bit per 4x4 block.
6	31:28	Skip8x8Pattern This field indicates whether each of the four 8x8 sub macroblocks is using the predicted MVs and will not be explicitly coded in the bitstream (the sub macroblock will be coded as direct mode). It contains four 1-bit subfields, corresponding to the 4 sub macroblocks in sequential order. The whole macroblock may be actually coded as B_Direct_16x16 or B_Skip, according to the macroblock type conversion rules described in a later sub section. This field is only valid for a B slice. It is ignored by hardware for a P slice. Hardware also ignores this field for an intra macroblock. 0 in a bit – Corresponding MVs are sent in the bitstream 1 in a bit – Corresponding MVs are not sent in the bitstream
	27	EnableCoeffClamp 1 = the magnitude of coefficients of the current MB will be clamped based on the clamping matrix

DWord	Bit	Description
		after quantization 0 = no clamping
	26	LastMbFlag 1 – the current MB is the last MB in the current Slice 0 – the current MB is not the last MB in the current SliceReserved MBZ.
	25	SkipMbConvDisable This is a per-MB level control to enable and disable skip conversion. This field is ORed with SkipConvDisable field. This field is only valid for a P or B slice. It must be zero for other slice types. Rules are provided in Section Macroblock Type Conversion Rules 0 - Enable skip type conversion for the current macroblock 1 - Disable skip type conversion for the current macroblock
	24	Reserved MBZ.
	23:16	Reserved. Ignored by HW, this field will be re-derived internally. (was QpPrimeV. For 8-bit pixel data, QpCr is the same as QpPrimeCr, and it takes on a value in the range of 0 to 51, positive integer.)
	15:8	Reserved. IIgnored by HW, this field will be re-derived internally. (Was QpPrimeU. For 8-bit pixel data, QpCb is the same as QpPrimeCb, and it takes on a value in the range of 0 to 51, positive integer.)
	7:0	QpPrimeY This is the per-MB QP value specified for the current MB. For 8-bit pixel data, QpY is the same as QpPrimeY, and it takes on a value in the range of 0 to 51, positive integer. Note: This value may differ from the actual codes, when HW QRC is on
7 to 9	31:0 Each	For intra macroblocks, definition of these fields are specified in Inline data subfields for an Intra Macroblock. For inter macroblocks, definition of these fields are specified in Inline data subfields for an Inter Macroblock .
10	31:24	MaxSizeInWord PAK should not exceed this budget accumulatively, otherwise it will trickle the PANIC mode.
	23:16	TargetSizeInWord PAK should use this budget accumulatively to decide if it needs to limit the number of non-zero

<table>
<tr><th>DWord</th><th>Bit</th><th>Description</th></tr>
<tr><td></td><td></td><td>coefficients.</td></tr>
<tr><td></td><td>15:0</td><td>Lambda_Or_RoundingOffset

When TQEnb=1, this 16-bit unsigned value multiplied by 2 is used as a lambda for the rate-distortion cost estimation in Trellis quantization (TQ). If the upper 4 bits are all set to 1 (0xFXXX), TQ is disabled and the regular quantizer is used. Thus, the valid range is 0~0xEFFF.

When TQEnb=0 or the upper 4 bits are all set to 1, the lower 4-bit value indicates the rounding precision (offset) for the regular quantizer

The inline data content of Dwords 4 to 6 is defined either for intra prediction or for inter prediction, but not both.

Inline data subfields for an Intra Macroblock

Dword	Bit	Description
7	31:16	LumaIntraMode[1] Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment table later in this section.
	15:0	LumaIntraMode[0] Specifies the Luma Intra Prediction mode for four 4x4 sub-block, four 8x8 block or one intra16x16 of a MB. 4-bit per 4x4 sub-block (Transform8x8Flag=0, Mbtype=0 and intraMbFlag=1) or 8x8 block (Transform8x8Flag=1, Mbtype=0, MbFlag=1), since there are 9 intra modes. 4-bit for intra16x16 MB (Transform8x8Flag=0, Mbtype=1 to 24 and intraMbFlag=1), but only the LSBit[1:0] is valid, since there are only 4 intra modes. See the bit assignment table later in this section.
8	31:16	LumaIntraMode[3] Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment table later in this section.
	15:0	LumaIntraMode[2] Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment later in this section.
9	31:8	Reserved : MBZ (Reserved for encocder turbo mode IntraResidueDataSize, when this is not 0, optional residue data are provided to the PAK; Reserved for decoder)
	7:0	IntraStruct This field contains 6 bits for IntraPredAvailFlags[5:0] and 2 bits for ChromaIntraPredMode. The IntraPredAvailFlags[4:0] (the lower 5 bits) have already included the effect of the constrained_intra_pred_flag. See the diagram later for the definition of neighbor position around the current MB or MB pair (in MBAFF mode). 1 – IntraPredAvailFlagY, indicates the values of samples of neighbor Y can be used in intra prediction for the current MB. 0 – IntraPredAvailFlagY, indicates the values of samples of neighbor Y is not available for intra prediction of the current MB. IntraPredAvailFlag-A and -E can only be different from each other when constrained_intra_pred_flag is equal to 1 and mb_field_decoding_flag is equal to 1 and the value of the mb_field_decoding_flag for the macroblock pair to the left of the current macroblock is equal to 0 (which can only occur

Dword	Bit	Description
		when MbaffFrameFlag is equal to 1). IntraPredAvailFlag-F is used only if it is in MBAFF mode, i.e. MbaffFrameFlag = 1, the current macroblock is of frame type, i.e. MbFieldFag = 0, and the current macroblock type is Intra8x8, i.e. IntraMbFlag = INTRA, IntraMbMode = INTRA_8x8, and Transform8x8Flag = 1. In any other cases IntraPredAvailFlag-A shall be used instead.

Bits	IntraPredAvailFlags Definition
7	IntraPredAvailFlagF – F (Left 8th row (-1,7) neighbor)
6	IntraPredAvailFlagA – A (Left neighbor top half)
5	IntraPredAvailFlagE – E (Left neighbor bottom half)
4	IntraPredAvailFlagB – B (Top neighbor)
3	IntraPredAvailFlagC – C (Top right neighbor)
2	IntraPredAvailFlagD – D (Top left corner neighbor)
1:0	ChromaIntraPredMode – 2 bits to specify 1 of 4 chroma intra prediction modes, see the table in later section.

Inline data subfields for an Inter Macroblock

DWord	Bit	Description
7	31:16	Reserved : MBZ
	15:8	SubMbPredMode (Sub-Macroblock Prediction Mode): If InterMbMode is INTER8x8, this field describes the prediction mode of the sub-partitions in the four 8x8 sub-macroblock. It contains four subfields each with 2-bits, corresponding to the four 8x8 sub-macroblocks in sequential order. This field is derived from sub_mb_type for a BP_8x8 macroblock. This field is derived from MbType for a non-BP_8x8 inter macroblock, and carries redundant information as MbType). If InterMbMode is INTER16x16, INTER16x8 or INTER8x16, this field carries the prediction modes of the sub macroblock (one 16x16, two 16x8 or two 8x16). The unused bits are set to zero. Bits [1:0]: SubMbPredMode[0] Bits [3:2]: SubMbPredMode[1] Bits [5:4]: SubMbPredMode[2] Bits [7:6]: SubMbPredMode[3]
	7:0	SubMbShape (Sub Macroblock Shape) This field describes the sub-block partitioning of each sub macroblocks (four 8x8 blocks). It contains

DWord	Bit	Description
		four subfields each with 2-bits, corresponding to the 4 fixed size 8x8 sub macroblocks in sequential order. This field is provided for MB with sub_mb_type equal to BP_8x8 only (B_8x8 and P_8x8 as defined in DXVA). Otherwise, this field is ignored by hardware Bits [1:0]: SubMbShape[0] – for 8x8 Block 0 Bits [3:2]: SubMbShape[1] – for 8x8 Block 1 Bits [5:4]: SubMbShape[2] – for 8x8 Block 2 Bits [7:6]: SubMbShape[3] – for 8x8 Block 3 Blocks of the MB is numbered as follows : 01 23 Each 2-bit value [1:0] is defined as : 00 – SubMbPartWidth=8, SubMbPartHeight=8 01 – SubMbPartWidth=8, SubMbPartHeight=4 10 – SubMbPartWidth=4, SubMbPartHeight=8 11 – SubMbPartWidth=4, SubMbPartHeight=4
8	31:24	RefPicSelect[0][3] Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	23:16	RefPicSelect[0][2] Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	15:8	RefPicSelect[0][1] Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	7:0	RefPicSelect[0][0] Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
9	31:24	RefPicSelect[1] [3] Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table.

DWord	Bit	Description
	23:16	RefPicSelect[1][2] Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table.
	15:8	RefPicSelect[1][1] Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table.
	7:0	RefPicSelect[1][0] Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table.

Luma Intra Prediction Modes

Luma Intra Prediction Modes (LumaIntraPredModes) is defined in Definition of LumaIntraPredModes. It is further categorized as Intra16x16PredMode (Definition of Intra16x16PredMode), Intra8x8PredMode (Definition of Intra8x8PredMode) and Intra4x4PredMode (Definition of Intra4x4PredMode), operating on 16x16, 8x8 and 4x4 block sizes, respectively. The Figure illustrates the intra prediction directions geometrically for the Intra4x4 prediction. When a macroblock is subdivided, the intra prediction is performed for the subdivision in a predetermined order. For example, Numbers of Block4x4 in a 16x16 region shows the block order for Intra4x4 prediction. And Numbers of Block4x4 in an 8x8 region or numbers of Block8x8 in a 16x16 region shows the block order of Block8x8 in a 16x16 region or Block4x4 in an 8x8 region.

Definition of LumaIntraPredModes

LumaIntraPredModes [index]		Intra16x16PredMode	Intra8x8PredMode	Intra4x4PredMode
Index	Bit	MbType = [1...24] Transform8x8Flag = 0	MbType = 0 Transform8x8Flag = 1	MbType = 0 Transform8x8Flag = 0
0	15:12	MBZ	Block8x8 3	Block4x4 3 (0_0)
	11:8	MBZ	Block8x8 2	Block4x4 2 (0_1)
	7:4	MBZ	Block8x8 1	Block4x4 1 (0_2)
	3:0	Block16x16	Block8x8 0	Block4x4 0 (0_3)

RefIdxL0/1[3]	x	x	x	blk3	Bit 31:24

MB Neighbor Availability in Intra-Prediction Modes (IntraPredAvailFlags)

Current MB is labelled as X. For non-MBAFF mode, 4 neighbors, A, B, C, D, are depicted in the following picture and are defined as the following.

- MB D: top left neighbor of current MB X
- MB C: top right neighbor of current MB X
- MB B: top neighbor of current MB X

- MB A: left neighbor of the current MB X

mbAddrD D (top-left)	**mbAddrB** **B** (top)	**mbAddrC** **C** (top-right)
mbAddrA A (left)	**X** **CurrMbAddrX**	**N/A**
N/A	**N/A**	**N/A**

For MBAFF mode, the current MB is labelled as X0 or X1, 4 neighbor pairs, A0/A1, B0/B1, C0/C1, D0/D1, are depicted in the following picture and are defined as the following.

- MB D0: first MB of top left neighbor MB pair of current MB pair X0/X1
- MB D1: second MB of top left neighbor MB pair of current MB pair X0/X1
- MB C0: first MB of top right neighbor MB pair of current MB pair X0/X1
- MB C1: second MB of top right neighbor MB pair of current MB pair X0/X1
- MB B0: first MB of top neighbor MB pair of current MB pari X0/X1
- MB B1: second MB of top neighbor MB pair of current MB pari X0/X1
- MB A0: first MB of left neighbor MB pair of the current MB pair X0/X1
- MB A1: second MB of left neighbor MB pair of the current MB pair X0/X1

mbAddrD D0	mbAddrB B0	mbAddrC C0
mbAddrD+1 D1	mbAddrB+1 B1	mbAddrC+1 C1
mbAddrA A0	CurrMbAddrX X0 or	N/A
mbAddrA+1 A1	CurrMbAddrX X1	N/A

For a given macroblock X (or X0/X1), the 6 neighbor availability signals, namely, A, B, C, D, E, F, are defined as the following.

- IntraPredAvailFlagF – F: (Single neighbor pixel at the left 8th row (-1,7)
- IntraPredAvailFlagA – A (Left neighbor top half pixel group)
- IntraPredAvailFlagE – E (Left neighbor bottom half pixel group)
- IntraPredAvailFlagB – B (Top neighbor pixel group)
- IntraPredAvailFlagC – C (Top right neighbor pixel group)
- IntraPredAvailFlagD – D (Top left corner neighbor pixel)

The following table depicts the generation of IntraPredAvailFlags[5:0] signals in a condensed form. It should note that for most cases only one input neighbor signal is assigned for each condition. The exception is in the four places for deriving left neighbor A and E where the neighbor is only available if left neighbors (A0 and A1) are both available (A0&A1). Also note that F takes output value very similar to that for A except the two "AND" conditions, where F is assigned to A1 instead of (A0&A1).

Definition of intra-prediction neighbor availability calculation in MBAFF mode

Output è		D		B		C		A		E		F		
Current X \ Neighbor Y		Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	
X_0 (Top)	X-Frame	D_1	D_1	B_1	B_1	C_1	C_1	A_0	A_0 & A_1	A_0	A_0 & A_1	A_0	A_1	
	X-Field	D_1	D_0	B_1	B_0	C_1	C_0	A_0	A_0	A_1	A_0	A_0	A_0	
X_1 (Bottom)	X-Frame	A_0	A_1	X_0	N/A	0	0	A_1	A_0 & A_1	A_1	A_0 & A_1	A_1	A_1	
	X-Field	D_1	D_1	B_1	B_1	C_1	C_1	A_0	A_1	A_1	A_1	A_0	A_1	

In Definition of intra-prediction neighbor availability calculation in MBAFF mode, X-Frame or X-Field indicates the frame/field mode of the current MB; and Y-Frame or Y-Field indicates the corresponding neighbor MB for the given neighbor location, being upper left (D) or left (A) for example. Therefore, "Y-" takes the selected neighbor MB name as in the output cell in the same column. For example, for output D, if X1 is a frame MB, Y = A, if X1 is a field MB, Y = D.

For non-MBAFF mode, as A0=A1, B0=B1, C0=C1 and D0=D1, the neighbor assignment is degenerated into the following simple table. Here, E is assigned to the same as A and F is forced to 0.

Definition of intra-prediction neighbor availability calculation in non-MBAFF mode

Output è	D	B	C	A	E	F
X	D0	B0	C0	A0	A0	0

To further explain the neighbor assignment rules in Definition of intra-prediction neighbor availability calculation in MBAFF mode, the following table provides description for each condition. Please note that

this table is informative as it provides redundant information as in Definition of intra-prediction neighbor availability calculation in MBAFF mode.

Detailed explanation of intra-prediction neighbor availability calculation in MBAFF mode

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
				D	
X0	X-Frame	Y-Frame	D	D1	Top Frame MB uses [-1,-1] = D_31, thus D1 only, regardless D frame or field pair
(Top)	X-Frame	Y-Field	D	D1	
	X-Field	Y-Frame	D	D1	Top Field MB uses [-1,-2] = D_30, thus if D is frame pair, takes D1 (D1_14 pixel), and if D is field pair, takes D0 (D0_15 pixel)
	X-Field	Y-Field	D	D0	
X1	X-Frame	Y-Frame	A	A0	Bottom Frame MB uses [-1,15] = A_15, thus A0 (A0_15 pixel) if A is a frame pair, or A1 (A1_7 pixel), if A is a field pair
(Bottom)	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	D	D1	Bottom Field MB uses [-1,-1] = D_31, thus D1 only, regardless D frame or field pair
	X-Field	Y-Field	D	D1	
				B	
X0	X-Frame	Y-Frame	B	B1	Top Frame MB uses [0…15,-1] = B_31, thus B1 only, regardless B frame or field pair
(Top)	X-Frame	Y-Field	B	B1	
	X-Field	Y-Frame	B	B1	Top Field MB uses [0…15,-2] = B_30, thus if B is frame pair, takes B1 (B1_14 row), and if B is field pair, takes B0 (B0_15 row)
	X-Field	Y-Field	B	B0	
X1	X-Frame	Y-Frame	X	X0	Bottom Frame MB uses [0…15,15], thus X0 (X0_15 row)
(Bottom)	X-Frame	Y-Field	X	n/a	Note: X0 and X1 must have the same field type, this row is n/a.
	X-Field	Y-Frame	B	B1	Bottom Field MB uses [0…15,-1] = B_31, thus B1 only, regardless B frame or field pair
	X-Field	Y-Field	B	B1	
				C	
X0	X-Frame	Y-Frame	C	C1	Top Frame MB uses [16…23,-1] = C_31, thus C1 only, regardless C frame or field pair
(Top)	X-Frame	Y-Field	C	C1	
	X-Field	Y-Frame	C	C1	Top Field MB uses [16…23,-2] = C_30, thus if C is frame pair, takes C1 (C1_14 row), and if C is field pair, takes C0 (C0_15 row)
	X-Field	Y-Field	C	C0	
X1	X-Frame	Y-Frame	n/a	0	Bottom Frame MB doesn't have left-top

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
				D	
(Bottom)	X-Frame	Y-Field	n/a	0	neighbor by definition, thus forced to 0
	X-Field	Y-Frame	C	C1	Bottom Field MB uses [16…23,-1] = C_31, thus C1 only, regardless C frame or field pair
	X-Field	Y-Field	C	C1	
				A	
X0	X-Frame	Y-Frame	A	A0	First Half of Top Frame MB uses [-1,0…7], thus A0 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
(Top)	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A0	First Half of Top Field MB uses [-1,0..2..4..14], thus take A0 (if A is frame pair, takes A0 even lines, and if A is field pair, takes A0 first half)
	X-Field	Y-Field	A	A0	
X1	X-Frame	Y-Frame	A	A1	First Half of Bottom Frame MB uses [-1,16…23], thus A1 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
(Bottom)	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A0	First Half of Bottom Field MB uses [-1,1..3..15], thus take A0 (if A is frame pair, takes A0 odd lines, and if A is field pair, takes A1 first half)
	X-Field	Y-Field	A	A1	
				E	
X0	X-Frame	Y-Frame	A	A0	Second Half of Top Frame MB uses [-1,8…15], thus A0 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
(Top)	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A1	Second Half of Top Field MB uses [-1,16..18..30], thus take A1 (if A is frame pair, takes A1 even lines, and if A is field pair, takes A0 second half)
	X-Field	Y-Field	A	A0	
X1	X-Frame	Y-Frame	A	A1	Second Half of Bottom Frame MB uses [-1,24…31], thus A1 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
(Bottom)	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A1	Second Half of Bottom Field MB uses [-1,17..19..31], thus takes A1 (if A is frame pair, takes A1 odd lines, and if A is field pair, takes A1 second half)
	X-Field	Y-Field	A	A1	
				F	
X0	X-Frame	Y-Frame	A	A0	Top Frame MB uses [-1,7] = A_7 (odd location), thus A0 if A is frame pair and A1 if field pair
(Top)	X-Frame	Y-Field	A	A1	

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
				D	
	X-Field	Y-Frame	A	A0	Top Field MB uses [-1,14] = A_14 (even location), thus A0 regardless A frame or field pair
	X-Field	Y-Field	A	A0	
X1	X-Frame	Y-Frame	A	A1	Bottom Frame MB uses [-1,23] = A_23 (odd location), thus A1 regardless A frame or field pair
(Bottom)	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	A	A0	Bottom Field MB uses [-1,15] = A_15 (odd location), thus A0 if A is frame pair and A1 if A is field pair
	X-Field	Y-Field	A	A1	

Macroblock Type for Intra Cases

MbType follows two different tables according to whether the macroblock is an inter or intra macroblock according to IntraMbFlag.

For an intra macroblock, MbType, as defined in MbType definition for Intra Macroblock, carries redundant information as IntraMbMode. The notation I_16x16_x_y_z used in the table, 'x' is Intra16x16LumaPredMode, 'y' is ChromaCbpInd, and 'z' is LumaCbpInd, as defined in Sub field definition used by MbType for a macroblock with Intra16x16 prediction.

MbType definition for Intra Macroblock

Macroblock Type	MbType
I_4x4	0
I_8x8	0
I_16x16_0_0_0	1
I_16x16_1_0_0	2
I_16x16_2_0_0	3
I_16x16_3_0_0	4
I_16x16_0_1_0	5
I_16x16_1_1_0	6
I_16x16_2_1_0	7
I_16x16_3_1_0	8
I_16x16_0_2_0	9
I_16x16_1_2_0	Ah
I_16x16_2_2_0	Bh
I_16x16_3_2_0	Ch
I_16x16_0_0_1	Dh
I_16x16_1_0_1	Eh

I_16x16_2_0_1	Fh
I_16x16_3_0_1	10h
I_16x16_0_1_1	11h
I_16x16_1_1_1	12h
I_16x16_2_1_1	13h
I_16x16_3_1_1	14h
I_16x16_0_2_1	15h
I_16x16_1_2_1	16h
I_16x16_2_2_1	17h
I_16x16_3_2_1	18h
I_PCM	19h (used by HW)

Note: MbType here is identical as specified in DXVA 2.0.

For Intra_16x16 modes, the 5 bits of value (MbType – 1) have the following meanings.

Sub field definition used by MbType for a macroblock with Intra16x16 prediction

Bits	Description
4	LumaCbpInd – Luma Coded Block Pattern Indicator 0 means none of the luma blocks are coded. 1 means that at least one luma block is coded. 0 = SUBMODE_I16_L_0 1 = SUBMODE_I16_L_NZ In VME output, this field is forced to be 1 before adding 1 in Intra_16x16 mode.
3:2	ChromaCbpInd – Chroma Coded Block Pattern Indicator 00 means none of chroma blocks are coded. 01 means that only the chroma DC block is coded, but all AC blocks are not coded. 10 means that at least one AC chroma block is coded. 00 = SUBMODE_I16_C_0 01 = SUBMODE_I16_C_DC 10 = SUBMODE_I16_C_NZ 11 = Reserved In VME output, this field is forced to be 10 before adding 1 in Intra_16x16 mode. Programming Note: Adding 1 to MbType by VME hardware may have carry into this field. But as '11' is reserved, the carry-in doesn't propagate into bit 4 or higher. This allows software to update MbType, if desired, using the redundant LumaIntraPredModes information.
1:0	Intra16x16PredMode – Intra16x16 Prediction Mode These two bits carries redundant (identical) information as that in LumaIntraPredModes[0][0]. 0 = SUBMODE_I16_VER

Bits	Description
	1 = SUBMODE_I16_HOR 2 = SUBMODE_I16_DC 3 = SUBMODE_I16_PLANE

IntraMbMode definition

IntraMbMode [1:0]	Description	Supported by VME?	Used by PAK?
0	INTRA_16x16 (redundant with MbType)	Yes	Ignored
1	INTRA_8x8	Yes	Yes
2	INTRA_4x4	Yes	Yes
3	IPCM (redundant with MbType)	No	Ignored

As an alternative representation, MbType is logically the same as the following, except the I_PCM and I_NxN (i.e. I_4x4 and I_8x8) cases:

- 24 types of 16x16 intra modes: A+B+C+D:(1h – 18h)

MBTYPE_INTRA_16x16 1hA

- 4 Intra16x16 modes:

SUBMODE_I16_VER 0B

SUBMODE_I16_HOR 1B

SUBMODE_I16_DC 2B

SUBMODE_I16_PLN 3B

- 3 Chroma Cbp indices:

SUBMODE_I16_C_0 0C

SUBMODE_I16_C_DC 4C

SUBMODE_I16_C_NZ 8C

- 2 Luma Cbp indices:

SUBMODE_I16_L_0 0D

SUBMODE_I16_L_NZ ChD

Macroblock Type for Inter Cases

Sub-Macroblock Prediction Mode, SubMbPredMode, indicates the prediction mode for the sub-partitions. Prediction mode specifies prediction direction being forward (from L0), backward (from L1) or bi-directional (from both L0 and L1). Its meaning depends on InterMbMode. Definition of SubMbPredMode[i] provides the definition of the field.

- If InterMbMode is INTER16x16, only SubMbPredMode[0] is valid, it describes the prediction mode of the 16x16 macroblock. The other entries are set to zero by hardware.
- For AVC, SubMbPredMode[0] contains redundant information as encoded in MbType parameter.
- Note: SubMbPredMode[1]-[3] are intentionally set to zero to allow a simple LUT to derive MbType as described later.
- If InterMbMode is INTER16x8, and INTER8x16, only the first two entries SubMbPredMode[0] and SubMbPredMode[1] are valid, describing the sub-macroblock prediction mode.
- For AVC, SubMbPredMode[0]/[1] contains redundant information as encoded in MbType parameter.
- Note: SubMbPredMode[2]-[3] are intentionally set to zero to allow a simple LUT to derive MbType as described later.
- If InterMbMode is INTER8x8, each entry of SubMbPredMode describes the prediction mode of the sub-partition of an 8x8 sub-macroblock.
- For AVC, SubMbPredMode can be derived from sub_mb_type field for BP_8x8 macroblocks as defined in AVC spec.
- Note on Direct Sub-macroblock Prediction Mode: Direct prediction is not conveyed through SubMbPredMode, instead, it is carried through Direct8x8Pattern.

InterMbMode definition

MbSkipFlag	InterMbMode	Description
0	0	INTER16x16
0	1	INTER16x8
0	2	INTER8x16
0	3	INTER8x8
1	0	PSKIP/BSKIP16x16*
1	3	BSKIP
1	1, 2	Reserved
Used by PAK	Ignored by PAK	

* BSKIP16x16 is an optional non-standard but equivalent optimization.

Definition of SubMbPredMode based on InterMbMode

SubMbPredMode	INTER16x16	INTER16x8	INTER8x16	INTER8x8
Bit	MbType = [1...3]	MbType = [16h]	MbType = [4...15h]	MbType = [16h]
7:6	MBZ	MBZ	MBZ	Block8x8 3
5:4	MBZ	MBZ	MBZ	Block8x8 2
3:2	MBZ	Block16x8 1	Block8x16 1	Block8x8 1
1:0	Block16x16	Block16x8 0	Block8x16 0	Block8x8 0
	Ignored by PAK	Ignored by PAK	Ignored by PAK	Used by PAK

Definition of SubMbPredMode[i]

SubMbPredMode	Description	InterMbMode	VME Output	MvCountPred	Notes
0	Pred_L0	All	Yes	1	P or B Slice
1	Pred_L1	All	Yes	1	B Slice Only
2	BiPred	All	Yes	2	B Slice Only
3	Reserved	Reserved	Reserved	Reserved	Reserved

Sub-Macroblock Shape, SubMbShape[i], for i = 0…3, describes the shape of the sub partitions of the 8x8 sub-macroblock of a BP_8x8 macroblock. This field is only valid if InterMBMode is INTER8x8. They are defined in Definition of SubMbShape for an 8x8 region of a BP_8x8 macroblock (including BSKIP, BDIRECT). The parameters can be derived from sub_mb_type field as defined in AVC spec.

Note: These fields must be correctly set even for Direct or Skip 8x8 cases, the individual B_Direct_8x8 block is flagged by the Direct8x8Pattern variable.

Definition of SubMbShape for an 8x8 region of a BP_8x8 macroblock (including BSKIP, BDIRECT)

	Description			
SubMbShape	NumSubMbPart	SubMbPartWidth	SubMbPartHeight	MvCountShape
0	1	8	8	1
1	2	8	4	2
2	2	4	8	2
3	4	4	4	4

For an inter macroblock, MbType, carries redundant information as InterMbMode and SubMbPredMode. The next table provides the typical inter macroblock types and the following table Additional MbType definition with Direct/Skip for Inter Macroblock provides that with skip and direct modes. The definition of MbType for both P slice and B slice is the same and is equivalent to that for mb_type of a B slice in the AVC spec. As direct mode is indicated using a separate field Direct8x8Pattern, 0 is reserved for MbType.

Here, MVCount is the number of motion vectors actually encoded in the bitstream. It is informative. For a BP_8x8 or equivalent Skip/Direct macroblock, MVCount is the sum of the following term for the four 8x8 sub macroblock (with i = 0…3):

MvCountShape[i] * MvCountPred[i] * MvCountDirect[i]

where MvCountShape[i] is block count for sub macroblock [i], MvCountPred[i] is the motion vector count for each block of sub macroblock[i], and MvCountDirect[i] is the multiplier for direct mode for B Slice, indicating whether motion vectors are coded or not. It must be set to 1 for P slice. For B Slice, MvCountDirect[i] = !Direct8x8Pattern[i], which is 0 for a sub macroblock coded as direct mode and 1 otherwise.

In the tables, “DC” stands for “Don’t Care” as PAK hardware ignores these fields.

MbType definition for Inter Macroblock (and MbSkipflag = 0)

Additional MbType definition with Direct/Skip for Inter Macroblock

Macroblock Type	MbType	Xfrm 8x8	MbSkipFlag	Direct8x8Pattern	SubMbShape	SubMbPredMode	MvCount	Notes
P_Skip_16x16	1	-	1	DC	DC	DC	0	Skipped macroblock. Motion compensation like P_L0_16x16
B_Skip_16x16_4MVPair	16h	Vary	1	Fh	0	vary	0	Skipped macroblock. Motion compensation like B_8x8 with 8x8 subblocks, when direct_8x8_inference_flag is set to 1
B_Skip_16x16_16MVPair	16h	0	1	Fh	FFh	vary	0	Skipped macroblock. Motion compensation like B_8x8 with 4x4 subblocks, when direct_8x8_inference_flag is set to 0
B_Direct_16x16_4MVPair	16h	vary	0	Fh	0	vary	0	MbType coded as B_Direct_16x16. Motion compensation like B_8x8 with 8x8 subblocks, when direct_8x8_inference_flag is set to 1
B_Direct_16x16_16MVPair	16h	0	0	Fh	FFh	vary	0	MbType coded as B_Direct_16x16. Motion compensation like B_8x8 with 4x4 subblocks, when direct_8x8_inference_flag is set to 0

People might notice that B_DIRECT_16x16 and B_SKIP are mapped on BP_8x8 for AVC decoding interface in IT mode as the motion compensation operation for both modes are the same as BP_8x8. According to AVC Spec, motion vectors for B_DIRECT_16x16 and B_SKIP are derived from temporally co-located macroblock on an 8x8 sub macroblock basis if direct_8x8_inference_flag is set to 1 or on a 4x4 block basis if it is set to 0. For each sub macroblock or block, SubMbPredMode is derived, thus can any of the valid numbers. Motion vectors may also be different. In spatial direct mode, the motion vectors are subject to spatial neighbor macroblocks as well as co-located macroblock. The spatial prediction is based on the neighbor macroblocks, so the same spatial predicted motion vector applies to all sub macroblocks or blocks. However, under certain conditions, temporal predictor may replace (colZeroFlag) the spatial predictor for a given sub macroblock or block. Thus the motion vectors may differ.

In MbType definition for Inter Macroblock (and MbSkipflag = 0), the macroblock type names for major partitions nicely follow forms BP_MbPredMode_MbShape (like BP_L0_16x16) and B_MbPredMode0_MbPredMode1_MbShape (like B_L0_Bi_16x8). For minor partitions it is fixed as BP_MbShape as BP_8x8.

However, in Additional MbType definition with Direct/Skip for Inter Macroblock the macroblock types for Skip and Direct modes does not follow the same rule. The third field in P_Skip_16x16 or B_Direct_16x16_x indicates that “Skip” or “Direct” applies to the entire 16x16 macroblock, even though MbShape is 8x8 as

that in BP_8x8. In order to distinguish the SubMbShape being 8x8 or 4x4 for B_Skip and B_Direct, the fourth field is added. 4MVPair indicates up to 4 MV pairs are presented with SubMbShape equals to 0; and 16MVPair indicates up to 16 MV pairs are presented with SubMbShape equals to FFh. Also note that P_8x8ref0 is not specified in PAK input interface, it is up to hardware to detect and choose its packing format based on number of reference indices and reference index for the given macroblock.

Macroblock Type Conversion Rules

For improved coding efficiency the PAK hardware has the capability to convert macroblock types to use more efficiency coding modes such as DIRECT and SKIP. For an inter macroblock or a sub macroblock coded as DIRECT, no motion vector is needed in the bitstream for the macroblock or sub macroblock. If a macroblock is coded as SKIP, it only consumes one SKIP bit (no motion vector, no coefficients are coded). And infomaton about the macroblock is 'inferred' according to the rules stated in the AVC Spec.

As the input to PAK, the following signals can convey the information regarding DIRECT and SKIP:

- MbSkipFlag
- Direct8x8Pattern
- CodecBlockPattern (CbpY, CbpCb, CbpCr)

Such conversion can be enabled or disabled through the SLICE_STATE fields DirectConvDisable and SkipConvDisable as well as the in line command field MbSkipConvDisable.

A P slice doesn't support direct mode, it only supports P_Skip, which is equivalent to a 16_16_L0 prediction. Other prediction types cannot be converted to P_Skip. The following table describes the macroblock type conversion rules for a P slice. Here CBP = CbpY/CbpCb/CbpCr are the final computed results after quantization by the hardware. Note that hardware honors the input CbpY/CbpCb/CbpCr fields – if the value corresponding to a block is set to zero, the resulting CBP is also zero. The output mb_skip_flag and mb_type are the symbols coded in the bitstream as defined in the AVC spec. "DC" stands for "Don't care", "T" for "True".

Note that the internal condition of MV==MVP is subject to the precise rules stated in the AVC Spec as quoted below. Note that there are exceptions for P_Skip from the normal motion vector prediction rules.

Derivation process for luma motion vectors for skipped macroblocks in P and SP slices

This process is invoked when mb_type is equal to P_Skip.

Outputs of this process are the motion vector mvL0 and the reference index refIdxL0.

The reference index refIdxL0 for a skipped macroblock is derived as follows.

refIdxL0 = 0. (8-168)

For the derivation of the motion vector mvL0 of a P_Skip macroblock type, the following applies.

– The process specified in subclause 8.4.1.3.2 is invoked with mbPartIdx set equal to 0, subMbPartIdx set equal to 0, currSubMbType set equal to "na", and listSuffixFlag set equal to 0 as input and the output is assigned to mbAddrA, mbAddrB, mvL0A, mvL0B, refIdxL0A, and refIdxL0B.

– The variable mvL0 is specified as follows.

– If any of the following conditions are true, both components of the motion vector mvL0 are set equal to 0.

– mbAddrA is not available

– mbAddrB is not available

– refIdxL0A is equal to 0 and both components of mvL0A are equal to 0

– refIdxL0B is equal to 0 and both components of mvL0B are equal to 0

– Otherwise, the derivation process for luma motion vector prediction as specified in subclause 8.4.1.3 is invoked with mbPartIdx = 0, subMbPartIdx = 0, refIdxL0, and currSubMbType = "na" as inputs and the output is assigned to mvL0.

NOTE – The output is directly assigned to mvL0, since the predictor is equal to the actual motion vector.

Macroblock type conversion rule for an inter macroblock in a P slice

Input		Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
P_Skip_16x16	DC	DC	DC	1	1	-	Forced to P_Skip; Hardware will force CBP to zero and also ignore SkipConvDisable control. Hardware doesn't check for MV==MVP error condition
P_Skip_16x16	DC	DC	DC	0	0	0	Reverse convert to P_L0_16x16; Hardware will force CBP to zero but reversely convert MbType as P_L0_16x16 once it determines that Skip is not allowed.
BP _16x16_L0	0	0	T	1	1	-	Converted to P_Skip. Even input doesn't provide skip hint, hardware can performance the optimization by detecting CBP and MV==MVP condition.
BP _16x16_L0	0	0	T	0	0	0	Reverse back to P_L0_16x16; Hardware will reverse back to P_L0_16x16 even Skip conditions are met once it determines that Skip is not allowed.
BP _16x16_L0	1	0	T	T	0	0	Still coded as P_L0_16x16 = 0.

A B slice supports both direct and skip modes. The following table describes the macroblock type conversion rules for a B slice. Hardware does not verify MV==MVP condition for a Skip/Direct macroblock in a B Slice as no DMV is performed by hardware.

Macroblock type conversion rule for an inter macroblock in a B slice

Input			Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	DirectConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
B_Skip_8x8 B_Skip_4x4	DC	DC	DC	n/a	1	1	-	Forced to B_Skip; Hardware will force CBP to zero and also ignore SkipConvDisable control.
B_Skip_8x8 B_Skip_4x4	DC	DC	DC	n/a	0	0	0	REVERSE convert to B_Direct_16x16; Hardware will force CBP to zero and also reverse convert to B_Direct_16x16 when it discovers Skip is not allowed.
B_Direct_16x16_4MVPair/16MVPair	0	0	0	n/a	1	1	-	Converted to B_Skip. Hardware first converts to B_Direct_16x16 and then further to B_Skip if CBP = 0.
B_Direct_16x16_4MVPair/16MVPair	0	0	0	n/a	0	0	0	Converted to B_Direct_16x16. Hardware first converts to B_Direct_16x16 and stop there as it discovers Skip is not allowed even CBP=0.
B_Direct_16x16_4MVPair/16MVPair	1	0	0	n/a	DC	0	0	Converted to B_Direct_16x16. Hardware converts to B_Direct_16x16 and stops there even though CBP = 0 as input disallows Skip conversion.
B_Direct_16x16_4MVPair/16MV	DC	0	NZ	n/a	DC	0	0	Converted to

Input			Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	DirectConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
Pair								B_Direct_16x16. Hardware converts to B_Direct_16x16 and stops there because CBP != 0.
B_Direct_16x16_4MVPair/16MVPair	DC	1	DC	n/a	DC	0	16h	Stay as B_8x8. Hardware stays at B_8x8 and codes each sub macroblocks even all are direct.

The internal signal MbAffSkipAllowed is added to deal with a restriction on the frame/field flag (MbFieldFlag) which is unique to MBAFF. MbAffSkipAllowed is always set to 1 in non-MBAFF modes. In MBAFF mode, a macroblock pair may be both skipped only if its MbFieldFlag is the same as its available neighbor macroblock pair A or B if A or B is available (in that order), or is not 0 if A/B are both not available. Otherwise, one of the macroblocks in the pair must be coded.

To reduce the burden on software, PAK hardware handles the above restriction correctly. For the first MB in a pair, MbAffSkipAllowed is always set to 1. Therefore, hardware allows converting the first MB to Skip if skip conversion is enabled. For the second MB in a pair, hardware sets MbAffSkipAllowed to 0 if the following is true:

- The current MB Pair has different MbFieldFlag than its available neighbor A or B if A or B is available, or is not 0 if A/B are both not available
- And the first MB is coded as a SKIP (could be forced or converted)

Otherwise, it sets MbAffSkipAllowed to 1. As MbAffSkipAllowed is to 0 for the above condition, hardware will disallow Skip mode for the second MB. If the input signal forces it to Skip, hardware performs reverse-convertion to code it as P_L0_16x16 or B_Direct_16x16 with CBP = 0 for a macroblock in a P or B Slice. This means that hardware is able to correct the programming mistake by software. If the macroblock is not forced to skip, hardware simply disallows Skip conversion.

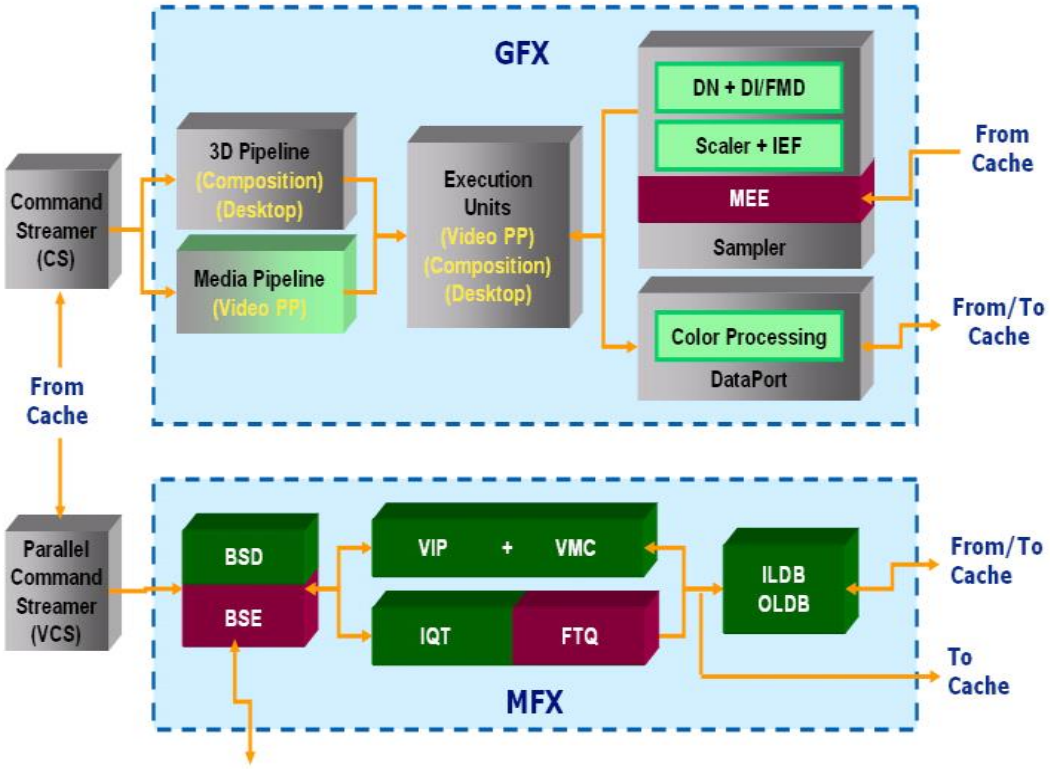
Software still has an option to disallow Skip Conversion on a per-MB basis using the MbSkipConvDisable control field in the inline command.

MFX Architecture

This section and the following sections of Media VDBOX contain the referential documentation on the Multi-Format Codecs, or MFX.

MFX Introduction

Multi-Format Codec (MFX) Engine is the hardware fixed function pipeline for decode and encoding. It includes multi-format decoding (MFD) and multi-format encoding (MFC).



MFC Overview

Multi-Format Codec (MFX) Engine is the hardware fixed function pipeline for decode and encoding. It includes multi-format decoding (MFD) and multi-format encoding (MFC).

Note: MFC only supports AVC (H.264).

Many decoding function blocks in MFD such as VIP, VMC, IQT, etc, are also used in encoding mode. Two blocks, FTQ and BSE, are encoding only.

The encoding process is partitioned across host software, the GPE engine, and the MFX engine. The generation of transport layer, sequence layer, picture layer, and slice header layer must be done in the host software. GP hardware is responsible for compressing from Slice Data Layer down to all macro-block and block layers. Specifically, GPE w/ VME acceleration is for motion vector estimation, motion estimation, and code decision.

The **VME**(*Video Motion Estimation*) is located next to all image processing units, such as DN (*denoise*) in GPE. MFX is for final bit packing and reconstructed picture generation.

MFC is operated concurrently with and independently from the GPE (3D/Media) pipeline with a separate command streamer. The two parallel engines have similar command protocol. They can be executed in

parallel with different context. For encoding, motion search, MB mode decision, and rate control are performed using GPE pipeline resources.

MFC is implemented to achieve the following objectives:

- Compliant with next generation high-definition optical video disc requirements, with sufficient performance headroom:
  - Support AVC 4:2:0 Main Profile and High Profile only (8-bit only), up to Level 4.1 resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be encoded. There is no support for Baseline, Extended, or High-10 Profiles.
- Performance requirements with MFX core frequency above 667MHz:
  - Real-time performance with 20% duty cycle or less.
  - Support concurrent decoding of two active HD bitstreams of different formats (for example, one AVC and one VC1 HD bitstream) and one active HD encoding.

As the result of this hardware partitioning, VPP and ENC are always running in GPE, and PAK is what runs exactly in MFC.

PAK - residue packing and entropy coding, including block transformation, quantization, data prediction, bitrate tuning and reference decoding. It delivers final packed bitstream and decoded key-frame reference:

- As the same as ENC, PAK is invoked on a Slice boundary; a single call of VPP can lead to multiple calls for PAK.
- Rate control is inside ENC and PAK only, not in VPP.
- PAK must always perform with reconstructed reference picture.

There is a general dependency of the three operation pipelines. Semaphores are inserted either according to frames or slices. The main CS will also be notified when the decoded reference is ready for the next frame set to be encoded. The detailed discussion will be found in a later section.

Host software is responsible for encoding the transport stream and all the sequence, picture, and slice layer/header in the bit-stream; the MFC system is responsible for compressing from Slice Data Layer down to all macro-block and block layers.

Sample Algorithmic Flow

Assuming all the hardware components are given, there are infinite usage possibilities left with intention for software to decide according to its own application needs depending upon the balanced requirement of coding speed, frame latency, power-consumption, and video quality, and depending upon the usage modes and user preferences (such as low-frame-rate-high-frame-quality vs. high-frame-rate-low-frame-quality).

The last part of this chapter, we illustrate a generic sample to show how a compression algorithm can be implemented to use our hardware.

Step 1. Application or driver initializes the encoder with desired configuration, including speed, quality, targeted bit-rate, input video info, and output format and restrictions.

Step 2. VPP - Application or driver feeds VPP one frame at a time in coded order with specified frame or field type, as well as transcoding information: motion vectors, coded complexity (i.e. bit size).

It will perform denoising and deblocking based on original and targeted bit-rate, and output additional

4 spatial variances and 2 temporal variances for each macroblock as well as the whole frame.

Step 3. ENC - Application or driver feeds ENC one coding slice buffer at a time including all VPP output. The frame level data is accessible to all slices.

a. Encoding setup unit (**ESE**) will set picture level quality parameters (including LUTs, and other costing functions) and set target bit-budget (TBB) and maximal bit-budget (MBB) to each macroblock based on rate-control (**RC**) scheme implemented. For B-frames, it will also make ME searching mode decision (either Fast, Slow or Uni-directional).
b. Loop over all macroblocks: calculate searching center (**MVP**) perform individual ME and IE (**MEE**). Multi-thread may be designed for HW according to a zigzag order for minimal dependency issue.
c. ENC make microblock level code decision (**CD**) outputs macroblock type, intra-mode, motion-vectors, distortions, as well as TBBs and MBBs.

Step 4. PAK - Application or driver feeds PAK one array of coded macroblocks covering a slice at a time, including all ENC output. Original frame buffer and reconstructed reference frame buffers are also available for PAK to access.

a. PAK may create bitstreams for all sequence, gop, picture, and slice level headers prior the first macroblock.
b. Loop over all macroblocks, accurate prediction block is constructed for either inter- or intra-predictions (**VMC** & **VIP**). If MB distortion is less than some predetermined threshold, for a B slice this step can be skipped as well as the Steps (c)-(e) and jump directly to Step (f); for a key slice the prediction calculated here will be directly used as the reference thus it jumps to Step (e) after this step.
c. Differencing the predicted block from the original block derives the residue block. Forward transformation and quantization (**FTQ**) is performed. For B slice, it will jump to Step (f) right after. For other types of slice, Steps (d) and (e) can be performed in a thread in parallel with Step (f) and beyond.
d. This is for accurate construction of reference pictures. Inverse quantization and inverse transformation (**IQT**) are performed and added to the predictions to have the decoded blocks.
e. **ILDB** is applied accordingly to the reconstructed blocks.
f. Meanwhile macroblock codes: including its configuration info (types and modes), motion info (motion vectors and reference ids), and residual info (quantized coefficients), are collected for packing (**BSE**) in the following sub-steps:
    i. Code clean-up (in **MPR**). Check and verify Mbtype and Cbps, use Skip or Zero respectively if one can. In principle, when there are equivalent codes, use the simple one.
    ii. Drop dependency (in **MPR**). Calculate relative codes from the absolute codes by associate them with neighborhood information. All neighborhood correlations are solved in this step.

iii. Unify symbols (in **SEC**). Translate relative codes into symbols, and table or context indices that are independent of the concept of syntax type.
iv. Entropy coding (**VLE**) on symbols.

g. Parsing bitstream data in RBSP form (in **VLE**), and output to application or driver.
h. By the end of each picture, write out the accurate actual data size to designate buffer for ENC to access.

Synchronization Mechanism

Encoding of a video stream can be broken down to three major steps (as explained in the previous section):

1. VPP: video-stream pre-processing
2. ENC: encoding, *that is,* code decision of inter-MVs and intra-modes
3. PAK: bit-stream packing
    a. residual calculation, transformation, and quantization
    b. code bit-stream packing
    c. reference generation of keyframes

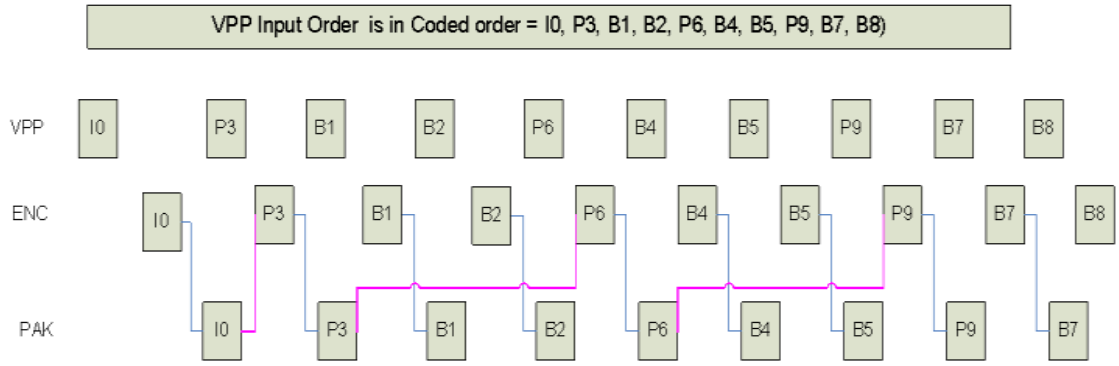
This section describes an architectural solution to map the first two steps in the GFX engine and the last step in the MFX engine. Since this mapping involves two OS-visible engines, managing them in parallel under one application is similar to the solution in earlier generations. Each engine has its own command streamers and has mechanisms to synchronize at required levels as described in the next sub-section.

Above three steps of encoding have dependencies in processing based on

i. functional pipeline order, *i.e.* on a given frame, VPP needs to be performed first, then ENC, then PAK and finally MFD (*Multi-Format Decoding*) for key reference frame generation.
ii. I-frames are key frames for P and B, they have to be first in every pipe-stage.
iii. P-frames are key frames for B frames and therefore P frames are processed first before the dependent B frames
iv. GFX Engine is time slice to work on either VPP or ENC frame as we discussed in the previous chapter.
v. PAK + MFD are executed on the same frame in the MFX engine by macro-block level pipelining within a slice. It should be noted that for the sake of simplicity, an entire frame (potentially multiple slices) are processed in the corresponding engine and no smaller granularity of switching is allowed between the functional pipeline stages.

Three steps of the encoding can be interleaved on two engines in the following way on a frame by frame basis.

Command Stream Synchronization



Restrictions

MFC implementation is subject to the following limitations.

- Context switching within MFC and with Graphics Engine occurs only at frame boundary to minimize the amount of information that needs to be tracked and maintained.

MFD Overview

When used for decoding, we also refer to the MFX Engine as the MFD Engine.

The Multi-Format Decoder (MFD) is a hardware fixed function pipeline for decoding the three-video codec format and one image compression codec format: AVC (H.264), VC-1, MPEG2, and JPEG.

- Compliant with next generation high-definition optical video disc requirements, with sufficient performance headroom:
    - Support AVC 4:2:0 Main and High (8-bit only) Profile only (no support for Baseline, Extended and High-10 Profiles), up to Level 5.1 (max 983,040 MB/s, max 36,864 MB/frame, and at most one dimension can reach 4K pixel) resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded.
        - Allow a B-picture (frame or field) as a reference picture
- Support MVC 4:2:0 Stereoscopic Progressive Profile only, up to Level 5.1 (max 983,040 MB/s per view, max 36,864 MB/frame per view, and at most one dimension can reach 4K pixel) resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded.
    - Support VC1 4:2:0 Simple, Main and Advanced Profiles, up to Level 4 (max 491,520 MB/s and max 16,384 MB/frame; max only one dimension will be at 4K pixel) resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded.
        - Allow a B-field as a reference picture only in interlaced field decoding, no other modes.
    - Support MPEG2 HD Main Profile (4:2:0), up to High Level (1920x1152 pixels) and up to 80 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded. No support for SNR and spatial-scalability.

- Does not support B-picture as a reference picture.

- Support Baseline JPEG with five choma types (4:0:0, 4:1:1, 4:2:2, 4:2:0, and 4:4:4. No support for Extended DCT-based mode, Progressive mode, Lossless mode, nor Hierarchical mode.
  - H/W support 64Kx64K, but Surface State can support only up to 16kx16k

Features	Supported	Unsupported
Coding processes	Baseline sequential mode: • 8-bit pixel precision of source images • loadable 2 AC and 2 DC Huffman tables • 3 loadable quantization matrix for Y, U, V • Interleaved and non-interleaved Scans • Single and multiple Scans	Extended DCT-based mode, Lossless, Hierarchical modes: More than 8 bit pixel resolution, progressive mode, arithmetic coding, 4 AC and 4 DC Huffman tables (extended mode), predictive process (lossless), multiple frames (hierarchical)
Number of image channels	1 for grey image 3 for Y, Cb, Cr color image	4-th channel (usually alpha blending image)
Image resolution	Arbitrary image size up to 16K * 16K	Larger than 16K * 16K (64K * 64K is max. in the JPEG standard)
Chroma subsampling ratio	Chroma 4:0:0 (grey image) Chroma 4:1:1 Chroma 4:2:0 Chroma horizontal 4:2:2 Chroma vertical 4:2:2 Chroma 4:4:4	Any other arbitrary ratio, e.g., 3:1 subsampled chroma
Additional feature (post-processing)	Image rotation: 90/180/270 degrees	

  - H/W does not impose restriction on picture frame aspect ratio, but is bounded by a max 256 MBs (4096 pixels) per dimension programmable at the H/W interface specifications.
    - For example, supporting HD video resolution 1920x1080/60i, 1920x1080/24p, 1280x720/60p

- Performance requirements with MFX core frequency above 1GHz
  - Real-time performance around 10% duty cycle
  - Support concurrently decoding of at least two active HD bitstreams of different formats (For example, one AVC and one VC1 HD bitstream)

- The parsing of transport layer and sequence layer is not performed in this hardware, and is required to be done in the host software.
- The MFD hardware pipeline is operated concurrently with and independently from the Graphics (3D/Media) pipeline with separate command streamer. The two parallel engines are designed with the similar command protocol. They can be executed in parallel with different context.
- Local storages and buffers along the hardware pipeline are kept at minimum. For example, there is no on-die row-store memory. They are resided on the system memory. MFD is designed to hide the memory access latency (in both the row stores and in the motion compensation units) in maximizing its decoding throughput.
- Support the following operating modes:
    - VLD mode - operation starts from entropy decoding of the compressed bit stream (parsing Slice Header and Slice Data Layer in AVC , Picture layer, Slice layer and MB Layer in VC-1, and MB-layer in MPEG2), all the way, to the reconstruction of display picture, including in-loop and out-loop deblocking, if any.
        - Streamout mode - a new feature of the VLD mode in assisting transcoding during decoding. Selected uncompressed data (e.g. per MB MV information) will be sent out to the EU and the ME engine for encoding into a different format or for the purpose of transcaling and transrating. In addition, the uncompressed result may continue to be processed by the rest of pipeline as in VLD mode to generate the display picture for transcoding. That is, while intermediate data are streaming out to the memory, the MFD Engine continues its decoding as usual.
        - Streamout mode - a new feature of the VLD mode in assisting transcoding during decoding. Selected uncompressed data (e.g. per MB MV information) will be sent out to the EU and the ME engine (resided on the Sampler of the 3D Gx Pipeline) for encoding into a different format or for the purpose of transcaling and transrating. In addition, the uncompressed result may continue to be processed by the rest of pipeline as in VLD mode to generate the display picture for transcoding. That is, while intermediate data are streaming out to the memory, the MFD Engine continues its decoding as usual.
        - For JPEG, only VLD mode is supported (No IT mode). Host software decodes Frame and Scan layers (down to Scan header in the JPEG bit stream syntax) and sends all the corresponding information and Scan payload to the MFD hardware pipeline.
    - IT mode - when host software has already performed all the bit stream parsing of the compressed data and packaging the uncompressed result into a specific format (as a sequence of per-MB record) stored in memory. The hardware pipeline will fetch one MB record at a time and perform the rest of the decoding process as in VLD mode
    - Host software (Application) is responsible for parsing and decoding all the transport and program layers, and all sequence layers. These parameters are passed to Driver and forwarded to H/W as needed through different STATE commands. Host software is also responsible for separating non-video data (audio, meta and user data) from sending to H/W.
        - MFD Engine is only responsible for macro-block and block layers decoding, plus certain level of header decoding. For AVC MFD starts decoding from Slice Header; for

VC1, MFD starts decoding from Picture Header, and for MPEG2 decoding starts from MB Layer only.
        - For JPEG, MFD is responsible for ECS and block layers decoding.
- Support bitstream formats (compressed video data) for each codec
    - AVC - 2 formats
    - MVC - 2 formats
        - DXVA2 MVC Short Slice Format
        - DXVA2 AVC Long Slice Format Specification (exactly the same as AVC)
    - VC1 - 2 formats
        - Fully compliant to Picture Parameter and Slice Control Parameter interface definition
- MPEG2
    - MB Layer only, according to DXVA 1 Specification
- JPEG
    - ECS Layer

The MFX codec is designed to be a stateless engine, that it does not retain any history of settings (states) for the encoding/decoding process of a picture. Hence, driver must issue the full set of MFX picture state command sequence prior to process each new picture. In addition, driver must issue the full set of Slice state command sequence prior to process a slice.

- In particularly, RC6 always happens between frame boundaries. So at the beginning of every frame, all state information needs to be programmed. There is no state information as part of media context definition.

To activate the AVC deblocker logic for incoming uncompressed 4:2:0-only video stream, one can pack the uncompressed video stream to compliant with the IPCM MB data format (including ILDB control information) and feed them into the MFD engine in IT mode. Since the MFD Engine is in IPCM mode, transformation, inter and intra processing are all inactive.

Start Code Detection and removal are done in the CPU, but the Start Code Emulation Prevention Byte is detected and removed by the front-end logic in the MFD. The bitstream format for each codec and for each mode is specified in this document.

Codec specific information are based on the following released documents from third parties:

- Draft of Version 4 of H.264/AVC (ITU-T Recommendation H.264 and ISO/IEC 14496-10 (MPEG-4 part 10) Advanced Video Coding); JVT-O205d1.doc; dated 2005-05-30
- Final Draft SMPTE Standard: VC1 Compressed Video Bitstream Format and Decoding Process, SMPTE 421M, dated 2006-1-6; PDF file.
- MPEG2 Recommendation ITU T H.262 (1995 E), ISO/IEC 13818-2: 1995 (E); doc file.
- Digital Compression and Coding of Continuous-tone Still Images, ITU-T Rec. T.81 and ISO/IEC 10918-1: Requirements and guidelines September 18 1992; itu-t81[1].pdf

MFD Memory Interface

The Memory Arbitrator follows the pre-defined arbitration policy (as indicated in the following listing P0 to P11, in which P0 is the highest priority) to select the next memory request to service, then it will perform the TLB translation (translation to physical address in memory), and make the actual request to memory.

The Memory Arbitration unit is also responsible for capturing the return data from memory (read request) and forward it to the appropriate unit along the MFD Engine.

- Read streams: (all 64B requests)
    - Commands for BSD : linear (including indirect data) (P0)
    - Indirect DMA (P1)
    - Row store for BSD: linear (P5)
    - Row store for MPR: linear (P6)
    - MC ref cache fetch : tiled (P2)
    - Intra row store: linear (P9)
    - ILDB row store: linear (P10)
- Write streams: (all 64B requests)
    - Row store write for BSD: linear and can avoid partial writes (P3)
    - Row store write for MPR: linear and can avoid partial writes (P4)
    - Intra row store write: linear and can avoid partial writes (P7)
    - ILDB row store write: linear and can avoid partial writes (P8)
    - Final dest writes: tiled and can potentially be partial, two ways to avoid these partials: 1) either write garbage and buffers are aligned or 2) read-modify writes for dribble end of line cases (P11)

MFD Codec-Specific Commands

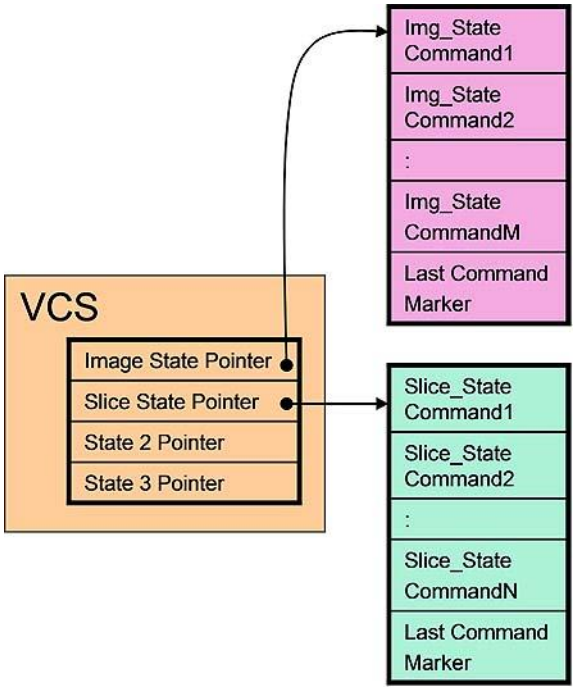
MFD hardware pipeline supports 3 different codec standards : AVC, VC1 and MPEG2. To make the interface flexible, each codec is designed with its own set of commands.

There are two categories of commands for each codec format : one set for VLD mode and one set for IT mode.

MFX State Model

The parallel video engine (PVE) supports two state delivery models: inline state model and indirect state model. For inline state model, the state commands (*_STATE) can be issued in batch buffers or ring buffers directly preceding object commands (*_OBJECT). In the indirect state model, the state commands are not placed in the batch buffers or ring buffers. Instead Indirect State Buffers provide state information (in the form of the above mentioned state commands) for the MFX pipeline. See MFX_STATE_POINTER for more details.

VCS (aka BCS) handles the difference of the two state delivery models. Therefore, the MFX pipeline always sees the state commands in both models. However, MFX hardware supports additional context save/restore of 'dynamic states'. Dynamic states are the internal signals that are persistent. This could be the CABAC context for macroblock encoding.



MFX State Model

The MFX codec is designed to be a stateless engine, that it does not retain any history of settings (states) for the encoding/decoding process of a picture. Hence, driver must issue the full set of MFX picture state command sequence prior to process each new picture. In addition, driver must issue the full set of Slice state command sequence prior to process a slice.

In particular, RC6 always happens between frame boundaries. So, at the beginning of every frame, all state information needs to be programmed. There is no state information as part of media context definition.

MFX Interruptability Model

MFX encoding and the encoding pipeline do not support interruption. All operations are frame based. Interrupts can only occur between frames; the driver will submit all the states at the beginning of each frame. Any state kept across frames is in MMIO registers that should be read between frames.

Software submits without any knowledge of where the parser head pointer is located. Also there is a non-deterministic amount of time for the new context to reach the command streamer. However, the state model for the MFX engine requires software to know exactly what state the pipeline is in at all times. This introduces cases where a preemption could occur during or after a state change without software ever knowing the state saved out to memory on the context switch.

Also, preemption is only allowed during the last macroblock in a row. Hardware cannot always perform a context switch when the new context is seen by the hardware. To avoid a switch during an invalid macroblock and to keep the state synchronized with software, there are two commands available that are used. MI_ARB_ON_OFF disables and enables preemption while MFX_WAIT ensures the context switch, if needed, preempts during macroblock execution. Below illustrates an example assuming VC1 VLD mode.

Command Ring/Batch	Notes
MI_ARB_ON_OFF = OFF	Disable preemption
S1	Inline or indirect state cmd 1
S2	Inline or indirect state cmd 2
S3	Inline or indirect state cmd 3
XXXX_OBJECT	Slice
MI_ARB_ON_OFF = ON	Enable preemption
MFX_WAIT	Allow preemption to occur while XXXX_OBJECT executes
MI_ARB_ON_OFF = OFF	Since arbitration is off again, state commands are allowed below
S4	Inline or indirect state cmd 4
S5	Inline or indirect state cmd 5
S6	Inline or indirect state cmd 6
XXXX_OBJECT	Slice
MI_ARB_ON_OFF = ON	Enable preemption
MFX_WAIT	Allow preemption to occur while XXXX_OBJECT executes
MI_ARB_ON_OFF = OFF	Since arbitration is off again, state commands are allowed below

Note that store DW commands may execute inside the preemption enabling window if needed.

Decoder Input Bitstream Formats

AVC Bitstream Formats - DXVA Short

Bitstream Buffer Address starts after the 3-byte start code, i.e. starts (and includes) at the NAL Header Byte. This byte must not be included in the Emulation Byte Detection Process.

AVC Bitstream Formats - DXVA Long

Bitstream Buffer Address starts after the 3-byte start code, i.e. starts (and includes) at the NAL Header Byte. This byte must not be included in the Emulation Byte Detection Process. Application will provide the Slice Header Skip Byte count (not including any possible Emulation Prevention Byte).

VC1 Bitstream Formats - Intel Long

Bitstream starts right at the MB layer, with any emulation byte crossing the header and MB layer being removed by application and the data length is adjusted.

MPEG2 Bitstream Formats - DXVA1

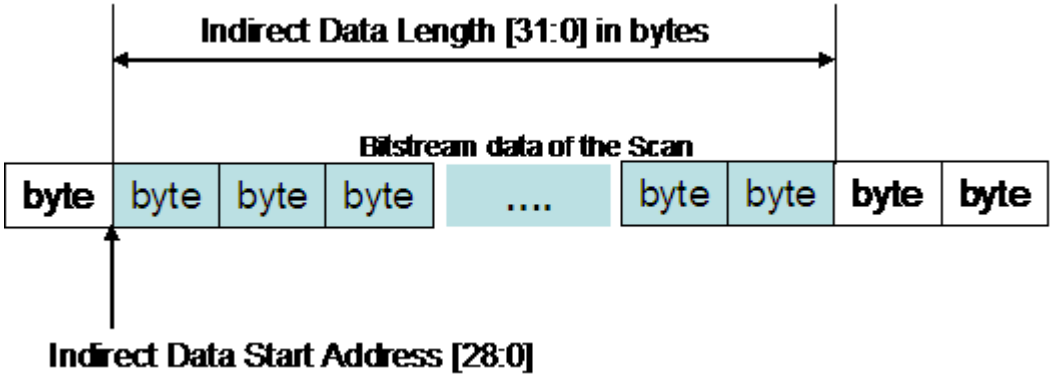
Bitstream buffer starts right at the very first MB data.

JPEG Bitstream Formats - Intel

Bitstream buffer starts right at the very first MCU data of each Scan.

The indirect data start address in MFD_JPEG_BSD_OBJECT specifies the starting Graphics Memory address of the bitstream data that follows the Scan header. It provides the byte address for the first MCU of the Scan. Different from MFD_MPEG2_BSD_OBJECT command, First MCU Bit Offset does not need to be specified because it is always set to zero.

Indirect data buffer for a Scan



The indirect data length in MFD_JPEG_BSD_OBJECT provides the length in bytes of the bitstream data for the Scan excluding Scan header. It includes the first byte of the first macroblock and the last byte of the last macroblock in the Scan. The Figure illustrates these parameters for a slice data.

Concurrent Multiple Video Stream Decoding Support

The natural place for switching across multiple streams is at the Slice boundary. Each Slice is a self-sustained unit of compressed video data and has no dependency with its neighbors (except for the Deblocking process). In addition, there is no interruptability within a Slice. However, when ILDB is invoked, the processing of some MBs will require neighbor MB information that crosses the Slice boundary. Hence, to limit the buffering requirement, in this version of hardware design, stream switching can only be performed at the picture boundary instead.

MFX Codec Commands Summary

DWord	Bit	Description
0	31:29	**Instruction Type =** GFXPIPE = 3h
	28:16	**3D Instruction Opcode =** PIPELINE_SELECT GFXPIPE[28:27 = 1h, 26:24 = 1h, 23:16 = 04h] (Single DW, Non-pipelined)
	15:1	**Reserved:** MBZ
	0	**Pipeline Select** 0: 3D pipeline is selected 1: Media pipeline is selected

Pipeline Type (28:27)	Opcode (26:24)	Sub Opcode (23:16)	Command	Definition Chapter
VC1 State				
2h	5h	0h	VC1_BSD_PIC_STATE	VC1 BSD
2h	5h	1h	Reserved	n/a
2h	5h	2h	Reserved	n/a
2h	5h	3h	VC1_BSD_BUF_BASE_STATE	VC1 BSD
2h	5h	4h	Reserved	n/a
2h	5h	5h-7h	Reserved	n/a
VC1 Object				
2h	5h	8h	VC1_BSD_OBJECT	VC1 BSD
2h	5h	9h-FFh	Reserved	n/a

MFX Decoder Commands Sequence

The MFX codec is designed to be a stateless engine, that it does not retain any history of settings (states) for the encoding/decoding process of a picture. Hence, driver must issue the full set of MFX picture state command sequence prior to process each new picture. In addition, driver must issue the full set of Slice state command sequence prior to process a slice.

In particular, RC6 always happens between frame boundaries. So at the beginning of every frame, all state information needs to be programmed. There is no state information as part of media context definition

Examples for AVC

The following gives a sample command sequence programmed by a driver

a) For Intel or DXVA2 AVC Long Slice Bitstream Format

MFX_PIPE_MODE_SELECT

MFX_SURFACE_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_BSP_BUF_BASE_ADDR_STATE

MFX_QM_STATE

VLD mode: MFX_AVC_PICID_STATE

MFX_AVC_IMG_STATE

MFX_AVC_DIRECTMODE_STATE

MFX_AVC_REF_IDX_STATE

MFX_AVC_WEIGHTOFFSET_STATE

MFX_AVC_SLICE_STATE

VLD mode: MFD_AVC_BSD_OBJECT

IT mode: MFD_IT_OBJECT

MI_FLUSH

b) For DXVA2 AVC Short Slice Bitstream Format (for VLD mode only)

MFX_PIPE_MODE_SELECT

MFX_SURFACE_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_BSP_BUF_BASE_ADDR_STATE

MFD_AVC_DPB_STATE

VLD mode: MFX_AVC_PICID_STATE

MFX_AVC_IMG_STATE

MFX_QM_STATE

MFX_AVC_DIRECTMODE_STATE

VLD mode : MFD_AVC_SLICEADDR_OBJECT

VLD mode: MFD_AVC_BSD_OBJECT

VLD mode : MFD_AVC_BSD_SLICEADDR_OBJECT

VLD mode: MFD_AVC_BSD_OBJECT

... repeat these four commands N-1 times for a N-slice picture

VLD mode: MFD_AVC_BSD_OBJECT (for the last slice of the picture)

MI_FLUSH

Examples for VC1

The following gives a sample command sequence programmed by a driver

a) For Intel Proprietary Long Bitstream Format

MFX_VC1_DIRECTMODE_STATE

MFX_VC1_PRED_PIPE_STATE

MFX_VC1_LONG_PIC_STATE

VLD mode: MFD_VC1_BSD_OBJECT

IT mode: MFD_IT_OBJECT

MI_FLUSH

b) For DXVA2 VC1 Compliant Bitstream Format (for VLD mode only)

MI_FLUSH (Video Pipeline Cache invalidate = 1)

MFX_VC1_DIRECTMODE_STATE

MFX_VC1_PRED_PIPE_STATE

MFX_VC1_SHORT_PIC_STATE

VLD mode: MFD_VC1_BSD_OBJECT

MI_FLUSH

c) For DXVA2 VC1 Compliant Bitstream Format (for VLD mode only), and field pair picture

Batch buffer for top-field

states....

Slice_objs...

MI_flush

store register immediate (if VC1 short format with interlaced field pic)

MI_flush

Batch buffer for bottom field

load register immediate (if VC1 short format with interlaced field pic)

MI_flush

states....

Slice_objs...

MI_flush

Examples for JPEG

The following gives a sample command sequence programmed by a driver

Programmed once at the start of decoding

MFX_PIPE_MODE_SELECT

MFX_PIPE_SURFACE_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_JPEG_PIC_STATE

Programmed at the start of Frame or Scan (These commands can be sent multiple times either before MFX_JPEG_PIC_STATE or before MFD_JPEG_BSD_OBJECT)

MFX_JPEG_HUFF_TABLE

MFX_QM_STATE

Programmed per Scan (These commands can be sent multiple times depending on each bit stream)

MFD_JPEG_ BSD_OBJECT

MI_FLUSH

MFX Pipe Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_WAIT

MFX_STATE_POINTER

MFX_PIPE_MODE_SELECT

The Encoder Pipeline Modes of Operation (Per Frame):

1. PAK Mode: VCS-command driven, setup by driver. Like the IT mode of decoder, it is executed on a per-MB basis. Hence, each PAK Object command corresponds to coding of only one MB.
    a. Normal Mode (including transcoding): receive per-MB control and data (MV, mb_type, cbp, etc.). It generates the output compressed bitstream as well as the reconstructed reference pictures, one MB at a time, for later use.

Encoder StreamOut Mode: to provide per-MB, per-Slice and per-Frame coding result and information (statistics) to the Host, Video Preprocessing Unit and ENC Unit to enhance their operations.

The Decoder Pipeline Modes of Operation (Per Frame):

1. VLD Mode: The output from the BSD (weight&offset/coeff/motion vectors record) can be sent in part (as specified) and to the remaining fixed function hardware pipeline to complete the decoding processing. The driver specifies through MFD commands of what to send out from the BSD unit and where to send the BSD output.
    a. For transcoding (including transrating and transcaling), part of the BSD output (a series of per-MB record) can be sent to memory for further processing to encode into a difference output format. This function is named as StreamOut. When StreamOut is active, not all MB information needs to be sent, only MVs and selective MB coding information.
2. IT Mode: In this mode, the BSD is not invoked. Instead host performs all the bitstream decoding and parsing; and the result are saved into memory in a specific per-MB record format. The MFD Engine VCS reads in these records one at time and finish the rest of the decoding (IT, MC, IntraPred and ILDB).

MB information is organized into two indirect data buffers, one for MVs and one for residue coefficients. As such, two indirect base address pointers are defined.

MFX_SURFACE_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_BSP_BUF_BASE_ADDR_STATE

MFX_PAK_INSERT_OBJECT

MFX_STITCH_OBJECT

MFX_QM_STATE

Bits	31:24	23:16	15:8	7:0
Dword 1	QuantMatrix[0][3]	QuantMatrix[0][2]	QuantMatrix[0][1]	QuantMatrix[0][0]

...	...	...	...	...
Dword 16	QuantMatrix[7][7]	QuantMatrix[7][6]	QuantMatrix[7][5]	QuantMatrix[7][4]

MFX_ STATE FQM

This is a frame-level state. Reciprocal Scaling Lists are always sent from the driver regardless whether they are specified by an application or the default/flat lists are being used. This is done to save the ROM (to store the default matrices) inside the PAK Subsystem. Hence, the driver is responsible for determining the final set of scaling lists to be used for encoding the current slice, based on the AVC Spec (Fall-Back Rules A and B). For encoding, there is no need to send the qm_list_flags[i], i=0 to7 and qm_present_flag to the PAK, since Scaling Lists syntax elements are encoded above Slice Data Layer.

FQM Reciprocal Scaling Lists elements are 16-bit each, conceptually equal to 1/ScaleValue. QM matrix elements are 8-bit each, equal to ScaleValue. However, in AVC spec., the Reciprocal Scaling Lists elements are not exactly equal to one-over of the corresponding Scaling Lists elements. The numbers are adjusted to simplify hardware implementation.

For all the description below, a scaling list set contains 6 4x4 scaling lists (or forward scaling lists) and 2 8x8 scaling lists (or forward scaling lists).

In MFX PAK mode, PAK needs both forward Q scaling lists and IQ scaling lists. The IQ scaling lists are sent as in MFD in raster scan order as shown in MFX_AVC_QM_STATE. But the Forward Q scaling lists are sent in transport form, i.e. column-wise raster order (column-by-column) to simplify the H/W.

Precisely, if the reciprocal forward scaling matrix is F[4][4], then the 16 word of the matrix will be set as the following:

For JPEG encoder, 16-bit precision is used for each element 1/QM matrix. The 32 DWords are used for 64 QM elements with the following data structure:

	Bits 15:0	Bits 31:16
DWord1	1/QM[0][0]	1/QM[1][0]
DWord2	1/QM[2][0]	1/QM[3][0]
DWord3	1/QM[4][0]	1/QM[5][0]

Bitplane Buffer

Bitplane coding is used in seven different cases in VC-1, although not all the seven syntax elements are present in the same picture header at the same time. The following list shows which syntax elements are coded as bitplanes in each picture header:

Progressive I and BI picture headers in AP: ACPRED, OVERFLAGS

Field interlace I and BI picture headers in AP: ACPRED, OVERFLAGS

Frame interlace I and BI picture headers in AP: FIELDTX, ACPRED, OVERFLAGS

Frame interlace P picture headers in AP: SKIPMB

Progressive P picture headers in SP and MP: MVTYPEMB, SKIPMB

Progressive P picture headers in AP: MVTYPEMB, SKIPMB

Field interlace B picture headers in AP: FORWARDMB

Frame interlace B picture headers in AP: DIRECTMB, SKIPMB

Progressive B picture headers in AP: DIRECTMB, SKIPMB

Progressive B picture headers in MP: DIRECTMB, SKIPMB

There are also seven different modes of coding the bitplane information. Except when the bitplane is coded in raw mode, the bitplane is decoded by the host and provided to the hardware in the bitplane buffer.

Since at most three bitplanes are encoded in any picture header, instead of using a complete byte for signaling the values of all the seven possible bitplanes for each MB, a more efficient approach is used with each byte divided in two nibbles and each nibble carries the data of up to four bitplanes for one MB.

PictureType	Bits 3, 7	Bit 2, 6	Bits 1, 5	Bits 0, 4
I or BI	0	OVERFLAGS	ACPRED	FIELDTX
P	0	MVTYPEMB	SKIPMB	0
B	0	FORWARDMB	SKIPMB	DIRECTMB

The bytes containing the above defined nibbles are stored in the bitplane buffer in raster scan order. The bitplane buffer is a linear buffer with a buffer pitch (as defined by Bitplane Buffer Pitch field in VC1_BSD_PIC_STATE command). When the number of macroblock in a row is odd, the last byte of the row containing the last macroblock in bits 0-3. The first macroblock of the next row starts at the next pitch offset from the first macroblock of the current row.

The bitplane buffer structure must be sent once per picture only if there is one or more syntax elements coded as bitplanes in the picture header.

Video Codecs

The following sections contain the various registers for video codec support. Specifically, the codec types supported are:

Supported Codec Types
Advanced Video Coding (AVC)/ H.264/MPEG-4 Part 10 (MVC)
MPEG-2 (H.222/H.262) -- Used in Digital Video Broadcast and DVDs
VC1 -- SMPTE 421M, known informally as VC-1
VP8 -- Video compression format
JPEG and MJPEG -- A video format in which video gram or interlaced field of a digital video sequence is compressed separately as a JPEG image
Other Codec Functions

Internal Media Rowstore table - An internal Media Rowstore Storage is added to reduce memory read/write to save power. If the internal Media Rowstore exists, driver should use the storage as the following table indicates.

AVC/VC1/MPEG2/JPEG/VP8 Decoder/Encoder:

[BSD is bitstream decoder rowstore; MPR is Motion Prediction rowstore; IP is Intra Prediction rowstore; VLF is loop filter rowstore; VDE is VDENC rowstore]

Codec	Mode	Frame Width	BSD	MPR	IP	VLF	VDENC	BSD Addr	MPR Addr	IP Addr	VLF ADDR	VDENC ADDR
VDENC AVC	Frame	<= 4k	N	Y	Y	Y	Y	0	256	512	768	0
	Field/Mbaff	<= 4k	N	Y	Y	N	Y	0	512	1024	N/A	0
VC1 Dec		N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
MPEG2		N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
JPEG		N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
VP8		<= 4k	Y	N	Y	Y	Y	0	N/A	256	512	1536

AVC (H.264)

AVC Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_AVC_IMG_STATE

A new command is added to support MPEG transport stream encapsulation of AVC bitstream in Encoder mode. This command should be used only when MPEG transport stream is needed.

MFX_MPEG_TS_CONTROL

MAX_QP_DELTA: Maximum QP delta is the Magnitude of QP delta between passes.

MAX_QP_DELTA is selected such that cumulative QP over all possible passes shouldn't exceed 51.

Example Configurations:

MAX Number of Passes	MAX_QP_DELTA
4	0xc
5	0xa
6	0x8
7	0x7

Commands
MFX_AVC_DIRECTMODE_STATE MFX_AVC_REF_IDX_STATE MFX_AVC_WEIGHTOFFSET_STATE

AVC Decoder Commands

These are decoder-only commands. They provide the pointer to the compressed input bitstream to be decoded.

MFD_AVC_DPB_STATE

NOTE modified from DXVA2 - The values in RefFrameList and UsedForReference_Flag are the primary means by which the H/W can determine whether the corresponding entries in RefFrameList, POCList, LTSTFrameNumList, and Non-ExistingFrame_Flag should be considered valid for use in the decoding process of the current picture or not. When RefFrameList[i] is marked to be invalid, the values of POCList[i][0], POCList[i][1], LTSTFrameNumList[i], UsedForReference_Flag[i], and Non-ExistingFrame_Flag[i] must all be equal to 0. When UsedForReference_Flag[i] = 0, the value of RefFrameList[i] must be marked invalid.

MFD_AVC_SLICEADDR

MFD_AVC_BSD_OBJECT

Inline Data Description for MFD_AVC_BSD_Object

MFD_AVC_PICID_STATE

NOTE 1: In AVC short format, PictureIDList has one-to-one corresponding to LongTermFrame_Flag list, Non-ExistingFrame_flag list, UsedForReference_Flag list, FrameNumList list in MFD_AVC_DPB_STATE.

NOTE 2: PictureIDList is only used to identify reference picture across frames. Hardware will convert the picture in the RefFrameList to PictureID before writing out DMV data and convert back to RefFrameList Index after reading out DMV data. The reference pictures and their orders in the RefFrameList can be changed across frames.

Session Decoder StreamOut Data Structure

When StreamOut is enabled, per MB intermediated decoded data (MVs, mb_type, MB qp, etc.) are sent to the memory in a fixed record format (and of fixed size). The per-MB records must be written in a strict raster order and with no gap (i.e. every MB regardless of its mb_type and slice type, must have an entry in the StreamOut buffer). Therefore, the consumer of the StreamOut data can offset into the StreamOut Buffer (**StreamOut Data Destination Base Address**) using individual MB addresses.

A StreamOut Data record format is detailed as follows:

DWord	Bit	Description
0	23	**Reserved MBZ**
	22-20	**EdgeFilterFlag** (AVC) / **OverlapSmoothFilter** (VC1)
	19-17	**CodedPatterDC** (for AVC only, **111b** for others) This field indicates whether DC coefficients are sent. 1 bit each for Y, U and V.
	16	**Reserved MBZ**
	15	**Transform8x8Flag** When it is set to 0, the current MB uses 4x4 transform. When it is set to 1, the current MB uses 8x8 transform. The transform_szie_8x8_flag syntax element, if present in the output bitstream, is the same as this field. However, whether transform_szie_8x8_flag is present or not in the output bitstream depends on several conditions: This field is only allowed to be set to 1 for two conditions: It must be 1 if **IntraMbFlag** = INTRA and **IntraMbMode** = INTRA_8x8 It may be 1 if **IntraMbFlag** = INTER and there is no sub partition size less than 8x8 Otherwise, this field must be set to 0. 0: 4x4 integer transform 1: 8x8 integer transform
	14	**MbFieldFlagMbFieldFlag** This field specifies whether current macroblock is coded as a field or frame macroblock in MBAFF mode. This field is exactly the same as FIELD_PIC_FLAG syntax element in non-MBAFF mode. Same as the mb_field_decoding_flag syntax element in AVC spec. >0 = Frame macroblock 1 = Field macroblock

DWord	Bit	Description
	13	**IntraMbFlag** This field specifies whether the current macroblock is an Intra (I) macroblock. I_PCM is considered as Intra MB. For I-picture MB (IntraPicFlag =1), this field must be set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes). 0: INTER (inter macroblock) 1: INTRA (intra macroblock)
	12-8	**MbType5Bits** This field is encoded to match with the best macroblock mode determined as described in the next section. It follows AVC encoding for inter and intra macroblocks.<
	7	**MbPolarity** FieldMB Polarity - vctrl_vld_top_field AVC
	6	**Reserved MBZ**
	5:4	**IntraMbMode** This field is provided to carry information partially overlapped with MbType. This field is only valid if **IntraMbFlag** = INTRA, otherwise, it is ignored by hardware.
	3	**Reserved MBZ**
	2	**MbSkipFlag** Reserved MBZ (DXVA Encoder). HW (VDSunit) doesn't have skip MB info. It sets to 1 if any of the sub-blocks is inter, uses predicted MVs, and skips sending MVs explicitly in the code stream. Currently H/W can provide this flag and is defaulted to 0 always.
	1:0	**InterMbMode** This field is provided to carry redundant information as that in MbType. It also carries additional information such as skip. This field is only valid if **IntraMbFlag** =INTER, otherwise, it is ignored by hardware.
1	31:16	**MbYCnt (Vertical Origin).** This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
	15:0	**MbXCnt (Horizontal Origin).** This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
2	31	**Conceal MB Flag.** This field specifies if the current MB is a conceal MB, use in AVC/VC1/MPEG2 mode.
	30	**Last MB of the Slice Flag.** This field indicate the current MB is a last MB of the slice. Use in AVC/VC1/MPEG2 mode.
	29:24	**Reserved**
	23:20	**CbpAcV** 0 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all

DWord	Bit	Description
		coefficient values are zero) 1 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding).
	19:16	**CbpAcU** 0 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero) 1 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding).
	15:0	**CbpAcY** 0 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero) 1 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). Bit15=Y0Sub0, Bit0=Y3Sub3
3	31:28	**Skip8x8Pattern** /> This field indicates whether each of the four 8x8 sub macroblocks is using the predicted MVs and will not be explicitly coded in the bitstream (the sub macroblock will be coded as direct mode). It contains four 1-bit subfields, corresponding to the 4 sub macroblocks in sequential order. The whole macroblock may be actually coded as B_Direct_16x16 or B_Skip, according to the macroblock type conversion rules described in a later sub section. This field is only valid for a B slice. It is ignored by hardware for a P slice. Hardware also ignores this field for an intra macroblock. 0 in a bit - Corresponding MVs are sent in the bitstream 1 in a bit - Corresponding MVs are not sent in the bitstream
	27:25	**Reserved**
	24:16	**NzCoefCountMB** - all coded coefficients input including AC/DC blocks in current MB. Range 0 to 384 (9 bits)
	15:8	MbClock16 - MB compute clocks in 16-clock unit.
	7	**mbz** (AVC) **/ QScaleType** (MPEG2)
	6:0	**QpPrimeY** (AVC) **/ QScaleCode** (MPEG2) The luma quantization index. This is the per-MB QP value specified for the current MB.
4 to 6	31:0 Each	For intra macroblocks, definition of these fields are specified in 1 For inter macroblocks, definition of these fields are specified in 2
7	31:24	**Reserved**
	23:20	**MvFieldSelect** (Ref polarity top or bottom bits) for VC1 and MPEG2 vcp_vds_mvdataR[162:159] VC1 vmd_vds_mt_vert_fld_selR[3:0] MPEG2
	19:12	**Reserved**
	11:10	**SubBlockCodeType V** (If 8x8, 8x4, 4x8, 4x4 type)

DWord	Bit	Description
	9:8	**SubBlockCodeType U** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	7:6	**SubBlockCodeType Y3** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	5:4	**SubBlockCodeType Y2** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	3:2	**SubBlockCodeType Y1** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	1:0	**SubBlockCodeType Y0** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
Inter Cases		
8	31:16	**MvFwd[0].y** - y-component of the forward motion vector of the 1 8x8 or 1 4x4 subblock
	15:0	**MvFwd[0].x** - x-component of the forward motion vector of the 1 8x8 or 1 4x4 subblock
9	31:0	**MvBck[0]** - the backward motion vector of the 1 8x8 or 1 4x4 subblock
10	31:0	**MvFwd[1]** - the forward motion vector of the 2 8x8 or 4 4x4 subblock
11	31:0	**MvBck[1]** - the backward motion vector of the 2 8x8 or 4 4x4 subblock
12	31:0	**MvFwd[2]** - the forward motion vector of the 3 8x8 or 8 4x4 subblock
13	31:0	**MvBck[2]** - the backward motion vector of the 3 8x8 or 8 4x4 subblock
14	31:0	**MvFwd[3]** - the forward motion vector of the 4 8x8 or 12 4x4 subblock
15	31:0	**MvBck[3]**> - the backward motion vector of the 4th 8x8 or 12 4x4 subblock
8 to 15	31:0	**Reserved MBZ**

Inline data subfields for an Intra Macroblock

DWord	Bit	Description
4	31:16	**LumaIndraPredModes[1]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. AVC: See the bit assignment table later in this section. VC1: MBZ. MPEG2: MBZ.
	15:0	**LumaIndraPredModes[0]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block, four 8x8 block or one intra16x16 of a MB. 4-bit per 4x4 sub-block (Transform8x8Flag=0, Mbtype=0 and intraMbFlag=1) or 8x8 block (Transform8x8Flag=1, Mbtype=0, MbFlag=1), since there are 9 intra modes. 4-bit for intra16x16 MB (Transform8x8Flag=0, Mbtype=1 to 24 and intraMbFlag=1), but only the LSBit[1:0] is valid, since there are only 4 intra modes.

DWord	Bit	Description
		AVC: See the bit assignment table later in this section. VC1: MBZ. MPEG2: MBZ.
5 AVC INTRA	31:16	**LumaIndraPredModes[3]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. AVC: See the bit assignment table later in this section. VC1: MBZ. MPEG2: MBZ.
	15:0	**LumaIndraPredModes[2]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. AVC: See the bit assignment later in this section. VC1: MBZ. MPEG2: MBZ.
6	31:8	Reserved (Reserved for encoder turbo mode **IntraResidueDataSize**, when this is not 0, optional residue data are provided to the PAK; Reserved for decoder)
	7:0	**MbIntraStruct** The IntraPredAvailFlags[4:0] have already included the effect of the constrained_intra_pred_flag. See the diagram later for the definition of neighbors position around the current MB or MB pair (in MBAFF mode). 1 - IntraPredAvailFlagX, indicates the values of samples of neighbor X can be used in intra prediction for the current MB. 0 - IntraPredAvailFlagX, indicates the values of samples of neighbor X is not available for intra prediction of the current MB. IntraPredAvailFlag-A and -E can only be different from each other when constrained_intra_pred_flag is equal to 1 and mb_field_decoding_flag is equal to 1 and the value of the mb_field_decoding_flag for the macroblock pair to the left of the current macroblock is equal to 0 (which can only occur when MbaffFrameFlag is equal to 1). IntraPredAvailFlag-F is used only if ○ it is in MBAFF mode, i.e. **MbaffFrameFlag** = 1, ○ the current macroblock is of frame type**,** i.e. **MbFieldFag** = 0, and ○ the current macroblock type is Intra8x8, that is, **IntraMbFlag** = INTRA, **IntraMbMode** = INTRA_8x8, and **Transform8x8Flag** = 1. In any other cases IntraPredAvailFlag-A shall be used instead.

DWord	Bit	Description
		<table><tr><th>Bits</th><th>IntraPredAvailFlags[4:0] Definition</th></tr><tr><td>7</td><td>**IntraPredAvailFlagF - F** (Left 8th row (-1,7) neighbor)</td></tr><tr><td>6</td><td>**IntraPredAvailFlagA - A** (Left neighbor top half)</td></tr><tr><td>5</td><td>**IntraPredAvailFlagE - E** (Left neighbor bottom half)</td></tr><tr><td>4</td><td>**IntraPredAvailFlagB - B** (Top neighbor)</td></tr><tr><td>3</td><td>**IntraPredAvailFlagC - C** (Top right neighbor)</td></tr><tr><td>2</td><td>**IntraPredAvailFlagD - D** (Top left corner neighbor)</td></tr><tr><td>1:0</td><td>**ChromaIntraPredMode -** 2 bits to specify 1 of 4 chroma intra prediction mode, see the table in later section.</td></tr></table>

Inline data subfields for an Inter Macroblock

DWord	Bit	Description
4	31:24	Reserved: MBZ (DXVA Decoder)
	23:16	Reserved: MBZ (DXVA Decoder)
	15:8	**SubMbPredModes**[bit 7:0] (Sub Macroblock Prediction Mode) This field describes the prediction mode of the sub macroblocks (four 8x8 blocks). It contains four subfields each with 2-bits, corresponding to the 4 fixed size 8x8 sub macroblocks in sequential order. This field is provided for MB with sub_mb_type equal to BP_8x8 only (B_8x8 and P_8x8 as defined in DXVA) This field is derived from MbType for a non-BP_8x8 inter macroblock, and carries redundant information as MbType) Bits [1:0]: SubMbPredMode[0] - for 8x8 Block 0 Bits [3:2]: SubMbPredMode[1] - for 8x8 Block 1 Bits [5:4]: SubMbPredMode[2] - for 8x8 Block 2 Bits [7:6]: SubMbPredMode[3] - for 8x8 Block 3 Blocks of the MB is numbered as follows : 0 1 2 3 Each 2-bit value [1:0] is defined as : 00 - Pred_L0

DWord	Bit	Description
		01 - Pred_L1 10 - BiPred **For VC1:** Bits [1:0]: "00"= Y0 Forward only, "01"= Y0 Backward only, "10"= Y0 Bi direction Bits [3:2]: SubMbPredMode[1] - for 8x8 Block 1 Bits [5:4]: SubMbPredMode[2] - for 8x8 Block 2 Bits [7:6]: SubMbPredMode[3] - for 8x8 Block 3
	7:0	**SubMbShape**[bit 7:0] (Sub Macroblock Shape) This field describes the sub-block partitioning of each sub macroblocks (four 8x8 blocks). It contains four subfields each with 2-bits, corresponding to the 4 fixed size 8x8 sub macroblocks in sequential order. This field is provided for MB with sub_mb_type equal to BP_8x8 only (B_8x8 and P_8x8 as defined in DXVA) This field is forced to 0 for a non-BP_8x8 inter macroblock, and effectively carries redundant information as MbType). Bits [1:0]: SubMbShape[0] - for 8x8 Block 0 Bits [3:2]: SubMbShape[1] - for 8x8 Block 1 Bits [5:4]: SubMbShape[2] - for 8x8 Block 2 Bits [7:6]: SubMbShape[3] - for 8x8 Block 3 Blocks of the MB is numbered as follows : 0 1 2 3 Each 2-bit value [1:0] is defined as : 00 - SubMbPartWidth=8, SubMbPartHeight=8 01 - SubMbPartWidth=8, SubMbPartHeight=4 10 - SubMbPartWidth=4, SubMbPartHeight=8 11 - SubMbPartWidth=4, SubMbPartHeight=4 For VC-1, This field indicates the transformation types used for luma components, 2 bits for each 8x8.
5	31:24	**Frame Store ID L0[3]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are

DWord	Bit	Description
		generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)
	23:16	**Frame Store ID L0[2]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. DWord	Bit	Description
	7:0	**Frame Store ID L1[0]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)

AVC Encoder PAK Commands

Each PAK Commands is composed of a command op-code DW and one or more command data DWs (inline data). The size of each command is specified as part of the op-code DW. Most of the commands have fixed size, except some are allowed to be of variable length.

There is an inherent order of executing MFC PAK commands that driver must follow.

MFC_AVC_PAK_OBJECT

PAK Object Inline Data Description

The Inline Data includes all the required MB encoding states, constitute part of the Slice Data syntax elements, MB Header syntax elements and their derivatives. It provides information for the following operations:

1. Forward and Inverse Transform
2. Forward and Inverse Quantization
3. Advanced Rate Control (QRC)
4. MB Parameter Construction (MPC)
5. CABAC/CAVLC encoding
6. Bit stream packing
7. Intra and inter-Prediction decoding loop
8. Internal error handling

These state/parameter values may subject to change on a per-MB basis, and must be provided in each MFC_AVC_PAK_OBJECT command. The values set for these variables are retained internally, until they are reset by hardware Asynchronous Reset or changed by the next MFC_AVC_PAK_OBJECT command.

The inline data has been designed to match the DXVA 2.0, with the exception of the starting byte (DW0:0-7) and the ending dword (DW7:0-31).

The Deblocker Filter Control flags (FilterInternalEdgesFlag, FilterTopMbEdgeFlag and FilterLeftMbEdgesFlag) are generated by H/W, which are depending on MbaffFrameFlag, CurrMbAddr, PicWidthInMbs and disable_deblocking_filter_idc states.

Current MB [x,y] address is not sent, it is assumed that the H/W will keep track of the MB count and current MB position internally.

<table>

</table>

DWord	Bit	Description
		Programming Note **Context:** PAK Object Inline Data Description When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.
	16	**Reserved: MBZ** (reserved for future use as **ExternalResidBufFlag** for turbo mode)
	15	**Transform8x8Flag** This field indicates that 8x8 transform is used for the macroblock. When it is set to 0, the current MB uses 4x4 transform. When it is set to 1, the current MB uses 8x8 transform. The transform_size_8x8_flag syntax element, if present in the output bitstream, is the same as this field. However, whether transform_szie_8x8_flag is present or not in the output bitstream depends on several other conditions. This field is only allowed to be set to 1 for two conditions: It must be 1 if **IntraMbFlag** = INTRA and **IntraMbMode** = INTRA_8x8 It may be 1 if **IntraMbFlag** = INTER and there is no sub partition size less than 8x8 Otherwise, this field must be set to 0. **Programming Note** **Context:** PAK Inline Object Data Description When SvcSliceState TcoeffLvlPredFlag=1, and AvcImgState EntropyCodingFlag is 1(CABAC), this field cannot be 1. 0: 4x4 integer transform 1: 8x8 integer transform
	14	**FieldMbFlag** This field specifies the field polarity of the current macroblock, as the mb_field_decoding_flag syntax element in AVC spec. This field specifies whether current macroblock is coded as a field or frame macroblock in MBAFF mode. It is exactly the same as FIELD_PIC_FLAG syntax element in non-MBAFF mode. 0 = Frame macroblock 1 = Field macroblock
	13	**IntraMbFlag** This field specifies whether the current macroblock is an Intra (I) macroblock. I_PCM is considered as Intra MB.

DWord	Bit	Description
		For I-picture MB (IntraPicFlag =1), this field must be set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes). 0: INTER (inter macroblock) 1: INTRA (intra macroblock)
	12:8	**MbType5Bits** This field is encoded to match with the best macroblock mode determined as described in the next section. It follows a unified encoding for inter and intra macroblocks according to AVC Spec.
	7	**FieldMbPolarityFlag** This field indicates the field polarity of the current macroblock. Within an MbAff frame picture, this field may be different per macroblock and is set to 1 only for the second macroblock in a MbAff pair if FieldMbFlag is set. Otherwise, it is set to 0. Within a field picture, this field is set to 1 if the current picture is the bottom field picture. Otherwise, it is set to 0. It is a constant for the whole field picture. This field is reserved and MBZ for a progressive frame picture. 0 = Current macroblock is a field macroblock from the **top** field 1 = Current macroblock is a field macroblock from the **bottom** field *Programming Note: Here bits [26:24] (MbAffFieldFlag and FiedlMbPolarityFlag) match with bits [10:8] of the Media Block Read message descriptor, simplifying the programming for message generation, as when MbAffFieldFlag is "1", kernels need to override the original "frame" surface state set for MBAFF frame picture.*
	6	MB Reserved: Inter MB converted to IPCM. This field is for HW purposes only. SW should not use it.
	5:4	**IntraMbMode** This field is provided to carry information partially overlapped with MbType. This field is only valid if **IntraMbFlag** = INTRA, otherwise, it is ignored by hardware..
	3	Reserved: MBZ
	2	**SkipMbFlag** By setting it to 1, this field forces an inter macroblock to be encoded as a skipped macroblock. It is equivalent to mb_skip_flag in AVS spec, indicating that a macroblock is inferred as a P_Skip (or B_Skip) in a P Slice (or B Slice). Hardware honors input MVs for motion prediction and forces CBP to zero. By setting it to 0, an inter macroblock will be coded as a normal inter macroblock. The macroblock may still be coded as a skipped macroblock, according to the macroblock type conversion rules

DWord	Bit	Description
		described in the later sub sections. This field can only be set to 1 for certain values of MbType. See details later. This field is only valid for an inter macroblock. For intra MB (bit 13 of this DW set to one), this bit must be set to zero. 0 = not a skipped macroblock 1 = is coded as a skipped macroblock
	1:0	**InterMbMode** This field is provided to carry redundant information as that encoded in MbType. This field is only valid if **IntraMbFlag** =0, otherwise, it is ignored by hardware.
4	31:16	Cbp4x4Y[bit 15:0] (Coded Block Pattern Y) For 4x4 sub-block (when Transform8x8flag = 0 or in intra16x16) : 16-bit cbp, one bit for each 4x4 Luma sub-block (not including the DC 4x4 Luma block in intra16x16) in a MB. The 4x4 Luma sub-blocks are numbered as blk0 1 4 5 bit15 14 11 10 lk2 3 6 7 bit13 12 9 8 blk8 9 12 13 bit7 6 3 2 blk10 11 14 15 bit5 4 1 0 The cbpY bit assignment is cbpY bit [15 - X] for sub-block_num X. For 8x8 block (when Transform8x8flag = 1) Only the lower 4 bits [3:0] are valid; the remaining upper bits [15:4] are ignored. The 8x8 Luma blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpY bit assignment is cbpY bit [3 - X] for block_num X. 0 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding).

DWord	Bit	Description
		Programming Note **Context:** PAK Object Inline Data Description When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.
4	15:8	MbYCnt (Vertical Origin). This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
	7:0	MbXCnt (Horizontal Origin). This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
5	31:16	Cbp4x4V (Coded Block Pattern Cr) Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cr sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpCr bit assignment is cbpCr bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored. For 4.2.2, [23:16] for U(Cb), and [31:24] ignored. For 4.4.4, the definition is the same as for luma component: 1bit per 4x4 block. **Programming Note** **Context:** PAK Object Inline Data Description When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.
5	15:0	Cbp4x4U (Coded Block Pattern Cb) Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cb sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0

DWord	Bit	Description
		The cbpCb bit assignment is cbpCb bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored. For 4.2.2, [7:0] for U(Cb), and [15:8] ignored. For 4.4.4, the definition is the same as for luma component: 1bit per 4x4 block. **Programming Note** **Context:** PAK Object Inline Data Description When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.
6	31:28	**Skip8x8Pattern** This field indicates whether each of the four 8x8 sub macroblocks is using the predicted MVs and will not be explicitly coded in the bitstream (the sub macroblock will be coded as direct mode). It contains four 1-bit subfields, corresponding to the 4 sub macroblocks in sequential order. The whole macroblock may be actually coded as B_Direct_16x16 or B_Skip, according to the macroblock type conversion rules described in a later sub section. This field is only valid for a B slice. It is ignored by hardware for a P slice. Hardware also ignores this field for an intra macroblock. 0 in a bit - Corresponding MVs are sent in the bitstream 1 in a bit - Corresponding MVs are not sent in the bitstream
	27	**EnableCoeffClamp** 1 = the magnitude of coefficients of the current MB will be clamped based on the clamping matrix after quantization 0 = no clamping
	26	**LastMbFlag** 1 - the current MB is the last MB in the current Slice 0 - the current MB is not the last MB in the current Slice - Reserved MBZ.
	25	**SkipMbConvDisable** This is a per-MB level control to enable and disable skip conversion. This field is ORed with SkipConvDisable field. This field is only valid for a P or B slice. It must be zero for other slice types. Rules are provided in Section Macroblock Type Conversion Rules.

<table>
<tr><th>DWord</th><th>Bit</th><th>Description</th></tr>
<tr><td></td><td></td><td>0 - Enable skip type conversion for the current macroblock
1 - Disable skip type conversion for the current macroblock</td></tr>

The inline data content of Dwords 4 to 6 is defined either for intra prediction or for inter prediction, but not both.

Inline data subfields for an Intra Macroblock

Dword	Bit	Description
7	31:16	**LumaIntraMode[1]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment table later in this section.
	15:0	**LumaIntraMode[0]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block, four 8x8 block or one intra16x16 of a MB. 4-bit per 4x4 sub-block (Transform8x8Flag=0, Mbtype=0 and intraMbFlag=1) or 8x8 block (Transform8x8Flag=1, Mbtype=0, MbFlag=1), since there are 9 intra modes. 4-bit for intra16x16 MB (Transform8x8Flag=0, Mbtype=1 to 24 and intraMbFlag=1), but only the LSBit[1:0] is valid, since there are only 4 intra modes. See the bit assignment table later in this section.
8	31:16	**LumaIntraMode[3]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment table later in this section.
	15:0	**LumaIntraMode[2]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment later in this section.

<table>
<tr><th>Dword</th><th>Bit</th><th>Description</th></tr>
<tr><td rowspan="2">9</td><td>31:8</td><td>Reserved: MBZ
(Reserved for encocder turbo mode IntraResidueDataSize, when this is not 0, optional residue data are provided to the PAK; Reserved for decoder)</td></tr>
<tr><td>7:0</td><td>IntraStruct

This field contains 6 bits for IntraPredAvailFlags[5:0] and 2 bits for ChromaIntraPredMode. The IntraPredAvailFlags[4:0] (the lower 5 bits) have already included the effect of the constrained_intra_pred_flag. See the diagram later for the definition of neighbor position around the current MB or MB pair (in MBAFF mode).

1 - IntraPredAvailFlagY, indicates the values of samples of neighbor Y can be used in intra prediction for the current MB.

0 - IntraPredAvailFlagY, indicates the values of samples of neighbor Y is not available for intra prediction of the current MB.

IntraPredAvailFlag-A and -E can only be different from each other when constrained_intra_pred_flag is equal to 1 and mb_field_decoding_flag is equal to 1 and the value of the mb_field_decoding_flag for the macroblock pair to the left of the current macroblock is equal to 0 (which can only occur when MbaffFrameFlag is equal to 1).

IntraPredAvailFlag-F is used only if

• It is in MBAFF mode, that is, MbaffFrameFlag = 1
• The current macroblock is of frame type, that is, MbFieldFag = 0
• The current macroblock type is Intra8x8, that is, IntraMbFlag = INTRA, IntraMbMode = INTRA_8x8, and Transform8x8Flag = 1

In any other cases IntraPredAvailFlag-A shall be used instead.

<table>

Inline data subfields for an Inter Macroblock

DWord	Bit	Description
7	31:16	**Reserved: MBZ**
	15:8	**SubMbPredMode (Sub-Macroblock Prediction Mode):** If **InterMbMode** is INTER8x8, this field describes the prediction mode of the sub-partitions in the four 8x8 sub-macroblock. It contains four subfields each with 2-bits, corresponding to the four 8x8 sub-macroblocks in sequential order. This field is derived from sub_mb_type for a BP_8x8 macroblock. This field is derived from **MbType** for a non-BP_8x8 inter macroblock, and carries redundant information as **MbType**). If **InterMbMode** is INTER16x16, INTER16x8 or INTER8x16, this field carries the prediction modes of the sub macroblock (one 16x16, two 16x8 or two 8x16). The unused bits are set to zero. Bits [1:0]: SubMbPredMode[0] Bits [3:2]: SubMbPredMode[1] Bits [5:4]: SubMbPredMode[2] Bits [7:6]: SubMbPredMode[3]
	7:0	**SubMbShape** (Sub Macroblock Shape) This field describes the sub-block partitioning of each sub macroblocks (four 8x8 blocks). It contains four subfields each with 2-bits, corresponding to the 4 fixed size 8x8 sub macroblocks in sequential order. This field is provided for MB with sub_mb_type equal to BP_8x8 only (B_8x8 and P_8x8 as defined in DXVA). Otherwise, this field is ignored by hardware Bits [1:0]: SubMbShape[0] - for 8x8 Block 0 Bits [3:2]: SubMbShape[1] - for 8x8 Block 1 Bits [5:4]: SubMbShape[2] - for 8x8 Block 2 Bits [7:6]: SubMbShape[3] - for 8x8 Block 3 Blocks of the MB is numbered as follows : 01 23 Each 2-bit value [1:0] is defined as : 00 - SubMbPartWidth=8, SubMbPartHeight=8 01 - SubMbPartWidth=8, SubMbPartHeight=4 10 - SubMbPartWidth=4, SubMbPartHeight=8 11 - SubMbPartWidth=4, SubMbPartHeight=4
8	31:24	**RefPicSelect[0][3]**

DWord	Bit	Description
		Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	23:16	**RefPicSelect[0][2]** Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	15:8	**RefPicSelect[0][1]** Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	7:0	**RefPicSelect[0][0]** Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
9	31:24	**RefPicSelect[1] [3]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table. For P- picture these bits must be set to zero.
	23:16	**RefPicSelect[1][2]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table. For P- picture these bits must be set to zero.
	15:8	**RefPicSelect[1][1]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table. For P- picture these bits must be set to zero.
	7:0	**RefPicSelect[1][0]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table. For P- picture these bits must be set to zero.

Luma Intra Prediction Modes

Luma Intra Prediction Modes (LumaIntraPredModes) is defined in Definition of LumaIntraPredModes. It is further categorized as Intra16x16PredMode, Intra8x8PredMode and Intra4x4PredMode, operating on 16x16, 8x8 and 4x4 block sizes, respectively. illustrates the intra prediction directions geometrically for

the Intra4x4 prediction. When a macroblock is subdivided, the intra prediction is performed for the subdivision in a predetermined order. For example, Numbers of Block4x4 in a 16x16 region shows the block order for Intra4x4 prediction, and Numbers of Block4x4 in an 8x8 region or numbers of Block8x8 in a 16x16 region shows the block order of Block8x8 in a 16x16 region or Block4x4 in an 8x8 region.

Definition of LumaIntraPredModes

LumaIntraPredModes [index]		Intra16x16PredMode	Intra8x8PredMode	Intra4x4PredMode
Index	Bit	MbType = [1...24] Transform8x8Flag = 0	MbType = 0 Transform8x8Flag = 1	MbType = 0 Transform8x8Flag = 0

MB Neighbor Availability in Intra-Prediction Modes (IntraPredAvailFlags)

Current MB is labelled as X. For non-MBAFF mode, 4 neighbors, A, B, C, D, are depicted in the following picture and are defined as the following.

- MB D: top left neighbor of current MB X
- MB C: top right neighbor of current MB X
- MB B: top neighbor of current MB X
- MB A: left neighbor of the current MB X

mbAddrD D (top-left)	**mbAddrB** B (top)	**mbAddrC** C (top-right)
mbAddrA A (left)	**CurrMbAddrX** X	N/A
N/A	N/A	N/A

For MBAFF mode, the current MB is labelled as X0 or X1, 4 neighbor pairs, A0/A1, B0/B1, C0/C1, D0/D1, are depicted in the following picture and are defined as the following.

- MB D0: first MB of top left neighbor MB pair of current MB pair X0/X1
- MB D1: second MB of top left neighbor MB pair of current MB pair X0/X1
- MB C0: first MB of top right neighbor MB pair of current MB pair X0/X1
- MB C1: second MB of top right neighbor MB pair of current MB pair X0/X1
- MB B0: first MB of top neighbor MB pair of current MB pari X0/X1
- MB B1: second MB of top neighbor MB pair of current MB pari X0/X1
- MB A0: first MB of left neighbor MB pair of the current MB pair X0/X1
- MB A1: second MB of left neighbor MB pair of the current MB pair X0/X1

mbAddrD D0	**mbAddrB** B0	**mbAddrC** C0
mbAddrD+1 D1	**mbAddrB+1** B1	**mbAddrC+1** C1
mbAddrA A0	**CurrMbAddrX** X0 or	N/A
mbAddrA+1 A1	**CurrMbAddrX** X1	N/A

For a given macroblock X (or X0/X1), the 6 neighbor availability signals, namely, A, B, C, D, E, F, are defined as the following.

- IntraPredAvailFlagF - F (Single neighbor pixel at the left 8th row (-1,7)

- IntraPredAvailFlagA - A (Left neighbor top half pixel group)
- IntraPredAvailFlagE - E (Left neighbor bottom half pixel group)
- IntraPredAvailFlagB - B (Top neighbor pixel group)
- IntraPredAvailFlagC - C (Top right neighbor pixel group)
- IntraPredAvailFlagD - D (Top left corner neighbor pixel)

The following table depicts the generation of IntraPredAvailFlags[5:0] signals in a condensed form. It should note that for most cases only one input neighbor signal is assigned for each condition. The exception is in the four places for deriving left neighbor A and E where the neighbor is only available if left neighbors (A0 and A1) are both available (A0&A1). Also note that F takes output value very similar to that for A except the two "AND" conditions, where F is assigned to A1 instead of (A0&A1).

Table: Definition of intra-prediction neighbor availability calculation in MBAFF mode

Output =>		D		B		C		A		E		F	
Current X \ Neighbor Y		Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field
X_0 (Top)	X-Frame	D_1	D_1	B_1	B_1	C_1	C_1	A_0	A_0 & A_1	A_0	A_0 & A_1	A_0	A_1
	X-Field	D_1	D_0	B_1	B_0	C_1	C_0	A_0	A_0	A_1	A_0	A_0	A_0
X_1 (Bottom)	X-Frame	A_0	A_1	X_0	N/A	0	0	A_1	A_0 & A_1	A_1	A_0 & A_1	A_1	A_1
	X-Field	D_1	D_1	B_1	B_1	C_1	C_1	A_0	A_1	A_1	A_1	A_0	A_1

In the table below, Definition of intra-prediction neighbor availability calculation in MBAFF mode, *X-Frame* or *X-Field* indicates the frame/field mode of the current MB; and *Y-Frame* or *Y-Field* indicates the corresponding neighbor MB for the given neighbor location, being upper left (D) or left (A) for example. Therefore, "Y-" takes the selected neighbor MB name as in the output cell in the same column. For example, for output D, if X1 is a frame MB, Y = A, if X1 is a field MB, Y = D.

For non-MBAFF mode, as A0=A1, B0=B1, C0=C1 and D0=D1, the neighbor assignment is degenerated into the following simple table. Here, E is assigned to the same as A and F is forced to 0.

Table: Definition of intra-prediction neighbor availability calculation in non-MBAFF mode

Output =>	D	B	C	A	E	F
X	D0	B0	C0	A0	A0	0

To further explain the neighbor assignment rules in Definition of intra-prediction neighbor availability calculation in MBAFF mode, the following table provides description for each condition. Please note that this table is **informative** as it provides redundant information as in Definition of intra-prediction neighbor availability calculation in MBAFF mode.

Table: Detailed explanation of intra-prediction neighbor availability calculation in MBAFF mode

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
			D		
X0 (Top)	X-Frame	Y-Frame	D	D1	Top Frame MB uses [-1,-1] = D_31, thus D1 only, regardless D frame or field pair
	X-Frame	Y-Field	D	D1	
	X-Field	Y-Frame	D	D1	Top Field MB uses [-1,-2] = D_30, thus if D is frame pair, takes D1 (D1_14 pixel), and if D is field pair, takes D0 (D0_15 pixel)
	X-Field	Y-Field	D	D0	
X1 (Bottom)	X-Frame	Y-Frame	A	A0	Bottom Frame MB uses [-1,15] = A_15, thus A0 (A0_15 pixel) if A is a frame pair, or A1 (A1_7 pixel), if A is a field pair
	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	D	D1	Bottom Field MB uses [-1,-1] = D_31, thus D1 only, regardless D frame or field pair
	X-Field	Y-Field	D	D1	
			B		
X0 (Top)	X-Frame	Y-Frame	B	B1	Top Frame MB uses [0...15,-1] = B_31, thus B1 only, regardless B frame or field pair
	X-Frame	Y-Field	B	B1	
	X-Field	Y-Frame	B	B1	Top Field MB uses [0...15,-2] = B_30, thus if B is frame pair, takes B1 (B1_14 row), and if B is field pair, takes B0 (B0_15 row)
	X-Field	Y-Field	B	B0	
X1 (Bottom)	X-Frame	Y-Frame	X	X0	Bottom Frame MB uses [0...15,15], thus X0 (X0_15 row)
	X-Frame	Y-Field	X	n/a	**Note:** X0 and X1 must have the same field type, this row is n/a.
	X-Field	Y-Frame	B	B1	Bottom Field MB uses [0...15,-1] = B_31, thus B1 only, regardless B frame or field pair
	X-Field	Y-Field	B	B1	
			C		
X0 (Top)	X-Frame	Y-Frame	C	C1	Top Frame MB uses [16...23,-1] = C_31, thus C1 only, regardless C frame or field pair
	X-Frame	Y-Field	C	C1	
	X-Field	Y-Frame	C	C1	Top Field MB uses [16...23,-2] = C_30, thus if C is frame pair, takes C1 (C1_14 row), and if C is field pair, takes C0 (C0_15 row)
	X-Field	Y-Field	C	C0	
X1 (Bottom)	X-Frame	Y-Frame	n/a	0	Bottom Frame MB doesn't have left-top neighbor by definition, thus forced to 0
	X-Frame	Y-Field	n/a	0	
	X-Field	Y-Frame	C	C1	Bottom Field MB uses [16...23,-1] = C_31, thus C1 only, regardless C frame or field pair
	X-Field	Y-Field	C	C1	
			A		
X0 (Top)	X-Frame	Y-Frame	A	A0	First Half of Top Frame MB uses [-1,0...7], thus A0 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair
	X-Frame	Y-Field	A	A0&A1	

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
			D		
					due to the mix
	X-Field	Y-Frame	A	A0	First Half of Top Field MB uses [-1,0..2..4..14], thus take A0 (if A is frame pair, takes A0 even lines, and if A is field pair, takes A0 first half)
	X-Field	Y-Field	A	A0	
X1 (Bottom)	X-Frame	Y-Frame	A	A1	First Half of Bottom Frame MB uses [-1,16...23], thus A1 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A0	First Half of Bottom Field MB uses [-1,1..3..15], thus take A0 (if A is frame pair, takes A0 odd lines, and if A is field pair, takes A1 first half)
	X-Field	Y-Field	A	A1	
			E		
X0 (Top)	X-Frame	Y-Frame	A	A0	Second Half of Top Frame MB uses [-1,8...15], thus A0 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A1	Second Half of Top Field MB uses [-1,16..18..30], thus take A1 (if A is frame pair, takes A1 even lines, and if A is field pair, takes A0 second half)
	X-Field	Y-Field	A	A0	
X1 (Bottom)	X-Frame	Y-Frame	A	A1	Second Half of Bottom Frame MB uses [-1,24...31], thus A1 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A1	Second Half of Bottom Field MB uses [-1,17..19..31], thus takes A1 (if A is frame pair, takes A1 odd lines, and if A is field pair, takes A1 second half)
	X-Field	Y-Field	A	A1	
			F		
X0 (Top)	X-Frame	Y-Frame	A	A0	Top Frame MB uses [-1,7] = A_7 (odd location), thus A0 if A is frame pair and A1 if field pair
	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	A	A0	Top Field MB uses [-1,14] = A_14 (even location), thus A0 regardless A frame or field pair
	X-Field	Y-Field	A	A0	
X1 (Bottom)	X-Frame	Y-Frame	A	A1	Bottom Frame MB uses [-1,23] = A_23 (odd location), thus A1 regardless A frame or field pair
	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	A	A0	Bottom Field MB uses [-1,15] = A_15 (odd

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
D					
	X-Field	Y-Field	A	A1	location), thus A0 if A is frame pair and A1 if A is field pair

Macroblock Type for Intra Cases

MbType follows two different tables according to whether the macroblock is an inter or intra macroblock according to IntraMbFlag.

For an intra macroblock, MbType, as defined in MbType definition for Intra Macroblock, carries redundant information as IntraMbMode. The notation I_16x16_x_y_z used in the table, 'x' is Intra16x16LumaPredMode, 'y' is ChromaCbpInd, and 'z' is LumaCbpInd, as defined in Sub field definition used by MbType for a macroblock with Intra16x16 prediction.

MbType definition for Intra Macroblock

Macroblock Type	MbType
I_4x4	0
I_8x8	0
I_16x16_0_0_0	1
I_16x16_1_0_0	2
I_16x16_2_0_0	3
I_16x16_3_0_0	4
I_16x16_0_1_0	5
I_16x16_1_1_0	6
I_16x16_2_1_0	7
I_16x16_3_1_0	8
I_16x16_0_2_0	9
I_16x16_1_2_0	Ah
I_16x16_2_2_0	Bh
I_16x16_3_2_0	Ch

Macroblock Type	MbType
I_16x16_0_0_1	Dh
I_16x16_1_0_1	Eh
I_16x16_2_0_1	Fh
I_16x16_3_0_1	10h
I_16x16_0_1_1	11h
I_16x16_1_1_1	12h
I_16x16_2_1_1	13h
I_16x16_3_1_1	14h
I_16x16_0_2_1	15h
I_16x16_1_2_1	16h
I_16x16_2_2_1	17h
I_16x16_3_2_1	18h
I_PCM	19h (used by HW)

Note: MbType here is identical as specified in DXVA 2.0.

For Intra_16x16 modes, the 5 bits of value (MbType - 1) have the following meanings.

Sub field definition used by MbType for a macroblock with Intra16x16 prediction

Bits	Description
4	**LumaCbpInd** - Luma Coded Block Pattern Indicator 0 means none of the luma blocks are coded. 1 means that at least one luma block is coded. 0 = SUBMODE_I16_L_0 1 = SUBMODE_I16_L_NZ In VME output, this field is forced to be 1 before adding 1 in Intra_16x16 mode.
3:2	**ChromaCbpInd** - Chroma Coded Block Pattern Indicator 00 means none of chroma blocks are coded. 01 means that only the chroma DC block is coded, but all AC blocks are not coded. 10 means that at least one AC

Bits	Description
	chroma block is coded. 00 = SUBMODE_I16_C_0 01 = SUBMODE_I16_C_DC 10 = SUBMODE_I16_C_NZ 11 = Reserved In VME output, this field is forced to be 10 before adding 1 in Intra_16x16 mode. *Programming Note: Adding 1 to MbType by VME hardware may have carry in to this field. But as '11' is reserved, the carry-in doesn't propagate into bit 4 or higher. This allows software to update MbType, if desired, using the redundant LumaIntraPredModes information.*
1:0	**Intra16x16PredMode** - Intra16x16 Prediction Mode These two bits carries redundant (identical) information as that in LumaIntraPredModes[0][0]. 0 = SUBMODE_I16_VER 1 = SUBMODE_I16_HOR 2 = SUBMODE_I16_DC 3 = SUBMODE_I16_PLANE

IntraMbMode definition

IntraMbMode [1:0]	Description	Supported by VME?	Used by PAK?
0	**INTRA_16x16 (redundant with MbType)**	Yes	Ignored
1	**INTRA_8x8**	Yes	Yes
2	**INTRA_4x4**	Yes	Yes
3	**IPCM (redundant with MbType)**	No	Ignored

As an alternative representation, MbType is logically the same as the following, except the I_PCM and I_NxN (i.e. I_4x4 and I_8x8) cases:

- 24 types of 16x16 intra modes: **A**+**B**+**C**+**D**: (1h - 18h)

MBTYPE_INTRA_16x16 1h A

  - 4 Intra16x16 modes:

SUBMODE_I16_VER 0 B

SUBMODE_I16_HOR 1 B

SUBMODE_I16_DC	2	B
SUBMODE_I16_PLN	3	B

- 3 Chroma Cbp indices:

SUBMODE_I16_C_0	0	C
SUBMODE_I16_C_DC	4	C
SUBMODE_I16_C_NZ	8	C

- 2 Luma Cbp indices:

SUBMODE_I16_L_0	0	D
SUBMODE_I16_L_NZ	Ch	D

Macroblock Type for Inter Cases

Sub-Macroblock Prediction Mode, SubMbPredMode, indicates the prediction mode for the sub-partitions. Prediction mode specifies prediction direction being forward (from L0), backward (from L1) or bi-directional (from both L0 and L1). Its meaning depends on InterMbMode. Definition of SubMbPredMode[i] provides the definition of the field.

- If InterMbMode is INTER16x16, only SubMbPredMode[0] is valid, it describes the prediction mode of the 16x16 macroblock. The other entries are set to zero by hardware.
    - For AVC, SubMbPredMode[0] contains redundant information as encoded in MbType parameter.
    - *Note: SubMbPredMode[1]-[3] are intentionally set to zero to allow a simple LUT to derive MbType as described later.*
- If InterMbMode is INTER16x8, and INTER8x16, only the first two entries SubMbPredMode[0] and SubMbPredMode[1] are valid, describing the sub-macroblock prediction mode.
    - For AVC, SubMbPredMode[0]/[1] contains redundant information as encoded in MbType parameter.
    - *Note: SubMbPredMode[2]-[3] are intentionally set to zero to allow a simple LUT to derive MbType as described later.*
- If InterMbMode is INTER8x8, each entry of SubMbPredMode describes the prediction mode of the sub-partition of an 8x8 sub-macroblock.
    - For AVC, SubMbPredMode can be derived from sub_mb_type field for BP_8x8 macroblocks as defined in AVC spec.
    - *Note on Direct Sub-macroblock Prediction Mode: Direct prediction is not conveyed through SubMbPredMode, instead, it is carried through Direct8x8Pattern.*

InterMbMode definition

MbSkipFlag	InterMbMode	Description
0	0	**INTER16x16**
0	1	**INTER16x8**
0	2	**INTER8x16**
0	3	**INTER8x8**

0	Pred_L0	All	Yes	1	P or B Slice
1	Pred_L1	All	Yes	1	B Slice Only
2	BiPred	All	Yes	2	B Slice Only
3	Reserved	Reserved	Reserved	Reserved	Reserved

Sub-Macroblock Shape, SubMbShape[i], for i = 0...3, describes the shape of the sub partitions of the 8x8 sub-macroblock of a BP_8x8 macroblock. This field is only valid if InterMBMode is INTER8x8. They are defined in Definition of SubMbShape for an 8x8 region of a BP_8x8 macroblock (including BSKIP, BDIRECT). The parameters can be derived from *sub_mb_type* field as defined in AVC spec.

Note: These fields must be correctly set even for **Direct** or **Skip** 8x8 cases, the individual B_Direct_8x8 block is flagged by the **Direct8x8Pattern** variable.

Definition of SubMbShape for an 8x8 region of a BP_8x8 macroblock (including BSKIP, BDIRECT)

	Description			
SubMbShape	NumSubMbPart	SubMbPartWidth	SubMbPartHeight	MvCountShape
0	1	8	8	1
1	2	8	4	2
2	2	4	8	2
3	4	4	4	4

For an inter macroblock, MbType, carries redundant information as InterMbMode and SubMbPredMode. MbType definition for Inter Macroblock (and MbSkipflag = 0) provides the typical inter macroblock types and Additional MbType definition with Direct/Skip for Inter Macroblock provides that with skip and direct modes. The definition of MbType for both P slice and B slice is the same and is equivalent to that for mb_type of a B slice in the AVC spec. As direct mode is indicated using a separate field Direct8x8Pattern, 0 is reserved for MbType.

Here, MVCount is the number of motion vectors actually encoded in the bitstream. It is informative. For a BP_8x8 or equivalent Skip/Direct macroblock, MVCount is the sum of the following term for the four 8x8 sub macroblock (with i = 0...3):

MvCountShape[i] * MvCountPred[i] * MvCountDirect[i]

where MvCountShape[i] is block count for sub macroblock [i], MvCountPred[i] is the motion vector count for each block of sub macroblock[i], and MvCountDirect[i] is the multipler for direct mode for B Slice, indicating whether motion vectors are coded or not. It must be set to 1 for P slice. For B Slice, MvCountDirect[i] = !Direct8x8Pattern[i], which is 0 for a sub macroblock coded as direct mode and 1 otherwise.

In the tables, "DC" stands for "Don't Care" as PAK hardware ignores these fields.

MbType definition for Inter Macroblock (and MbSkipflag = 0)

Macroblock Type	MbType	MbSkipFlag	Direct8x8Pattern	SubMbShape	SubMbPredMode	MVCount

Additional MbType definition with Direct/Skip for Inter Macroblock

Macroblock Type	Mb Type	Xfrm 8x8	MbSkip Flag	Direct8x8 Pattern	SubMb Shape	SubMb PredMode	MvCount	Notes
P_Skip_16x16	1	-	1	DC	DC	DC	0	Skipped macroblock. Motion compensation like P_L0_16x16
B_Skip_16x16_4MVPair	16h	vary	1	Fh	0	vary	0	Skipped macroblock. Motion compensation like B_8x8 with 8x8 subblocks, when **direct_8x8_inference_flag** is set to 1
B_Skip_16x16_16MVPair	16h	0	1	Fh	FFh	vary	0	Skipped macroblock. Motion compensation like B_8x8 with 4x4 subblocks, when **direct_8x8_inference_flag** is set to 0
B_Direct_16x16_4MVPair	16h	vary	0	Fh	0	vary	0	MbType coded as B_Direct_16x16. Motion compensation like B_8x8 with 8x8 subblocks, when

Macroblock Type	Mb Type	Xfrm 8x8	MbSkip Flag	Direct8x8 Pattern	SubMb Shape	SubMb PredMode	MvCount	Notes
								direct_8x8_inference_flag is set to 1
B_Direct_16x16_16MVPair	16h	0	0	Fh	FFh	vary	0	MbType coded as B_Direct_16x16. Motion compensation like B_8x8 with 4x4 subblocks, when **direct_8x8_inference_flag** is set to 0

People might notice that B_DIRECT_16x16 and B_SKIP are mapped on BP_8x8 for AVC decoding interface in IT mode as the motion compensation operation for both modes are the same as BP_8x8. According to AVC Spec, motion vectors for B_DIRECT_16x16 and B_SKIP are derived from temporally co-located macroblock on an 8x8 sub macroblock basis if direct_8x8_inference_flag is set to 1 or on a 4x4 block basis if it is set to 0. For each sub macroblock or block, SubMbPredMode is derived, thus can any of the valid numbers. Motion vectors may also be different. In spatial direct mode, the motion vectors are subject to spatial neighbor macroblocks as well as co-located macroblock. The spatial prediction is based on the neighbor macroblocks, so the same spatial predicted motion vector applies to all sub macroblocks or blocks. However, under certain conditions, temporal predictor may replace (colZeroFlag) the spatial predictor for a given sub macroblock or block. Thus the motion vectors may differ.

In MbType definition for Inter Macroblock (and MbSkipflag = 0), the macroblock type names for major partitions nicely follow forms *BP_MbPredMode_MbShape* (like BP_L0_16x16) and *B_MbPredMode0_MbPredMode1_MbShape* (like B_L0_Bi_16x8). For minor partitions it is fixed as *BP_MbShape* as BP_8x8.

However, in Additional MbType definition with Direct/Skip for Inter Macroblock the macroblock types for Skip and Direct modes does not follow the same rule. The third field in P_Skip_16x16 or B_Direct_16x16_x indicates that "Skip" or "Direct" applies to the entire 16x16 macroblock, even though MbShape is 8x8 as that in BP_8x8. In order to distinguish the SubMbShape being 8x8 or 4x4 for B_Skip and B_Direct, the fourth field is added. 4MVP**air** indicates upto 4 MV pairs are presented with SubMbShape equals to 0; and 16MVP**air** indicates up to 16 MV pairs are presented with SubMbShape equals to FFh.Also note that P_8x8ref0 is not specified in PAK input interface, it is up to hardware to detect and choose its packing format based on number of reference indices and reference index for the given macroblock.

Macroblock Type Conversion Rules

For improved coding efficiency the PAK hardware has the capability to convert macroblock types to use more efficiency coding modes such as DIRECT and SKIP. For an inter macroblock or a sub macroblock coded as DIRECT, no motion vector is needed in the bitstream for the macroblock or sub macroblock. If a macroblock is coded as SKIP, it only consumes one SKIP bit (no motion vector, no coefficients are coded). And information about the macroblock is 'inferred' according to the rules stated in the AVC Spec.

As the input to PAK, the following signals can convey the information regarding DIRECT and SKIP:

- MbSkipFlag
- Direct8x8Pattern
- CodecBlockPattern (CbpY, CbpCb, CbpCr)

Such conversion can be enabled or disabled through the SLICE_STATE fields DirectConvDisable and SkipConvDisable as well as the in line command field MbSkipConvDisable.

A P slice doesn't support direct mode, it only supports P_Skip, which is equivalent to a 16_16_L0 prediction. Other prediction types cannot be converted to P_Skip. The following table describes the macroblock type conversion rules for a P slice. Here CBP = CbpY/CbpCb/CbpCr are the final computed results after quantization by the hardware. Note that hardware honors the input CbpY/CbpCb/CbpCr fields - if the value corresponding to a block is set to zero, the resulting CBP is also zero. The output mb_skip_flag and mb_type are the symbols coded in the bitstream as defined in the AVC spec. *DC* stands for *Don't care*, *T* for *True*.

Note that the internal condition of MV==MVP is subject to the precise rules stated in the AVC Spec as quoted below. Note that there are exceptions for P_Skip from the normal motion vector prediction rules.

Derivation process for luma motion vectors for skipped macroblocks in P and SP slices

This process is invoked when mb_type is equal to P_Skip.

Outputs of this process are the motion vector mvL0 and the reference index refIdxL0.

The reference index refIdxL0 for a skipped macroblock is derived as follows.

refIdxL0 = 0. (8-168)

For the derivation of the motion vector mvL0 of a P_Skip macroblock type, the following applies.

- The process specified in subclause 8.4.1.3.2 is invoked with mbPartIdx set equal to 0, subMbPartIdx set equal to 0, currSubMbType set equal to "na", and listSuffixFlag set equal to 0 as input and the output is assigned to mbAddrA, mbAddrB, mvL0A, mvL0B, refIdxL0A, and refIdxL0B.

- The variable mvL0 is specified as follows.

- If any of the following conditions are true, both components of the motion vector mvL0 are set equal to 0.

- mbAddrA is not available

- mbAddrB is not available

- refIdxL0A is equal to 0 and both components of mvL0A are equal to 0

- refIdxL0B is equal to 0 and both components of mvL0B are equal to 0

- Otherwise, the derivation process for luma motion vector prediction as specified in subclause 8.4.1.3 is invoked with mbPartIdx = 0, subMbPartIdx = 0, refIdxL0, and currSubMbType = "na" as inputs and the output is assigned to mvL0.

NOTE - The output is directly assigned to mvL0, since the predictor is equal to the actual motion vector.

Macroblock type conversion rule for an inter macroblock in a P slice

Input		Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
P_Skip_16x16	DC	DC	DC	1	1	-	Forced to P_Skip; Hardware will force CBP to zero and also ignore SkipConvDisable control. Hardware doesn't check for MV==MVP error condition
P_Skip_16x16	DC	DC	DC	0	0	0	Reverse convert to P_L0_16x16; Hardware will force CBP to zero but reversely convert MbType as P_L0_16x16 once it determines that Skip is not allowed.
BP _16x16_L0	0	0	T	1	1	-	Converted to P_Skip. Even input doesn't provide skip hint, hardware can performance the optimization by detecting CBP and MV==MVP condition.
BP _16x16_L0	0	0	T	0	0	0	Reverse back to P_L0_16x16; Hardware will reverse back to P_L0_16x16 even Skip conditions are met once it determines that Skip is not allowed.
BP _16x16_L0	1	0	T	T	0	0	Still coded as P_L0_16x16 = 0.

A B slice supports both direct and skip modes. The following table describes the macroblock type conversion rules for a B slice. Hardware does not verify MV==MVP condition for a Skip/Direct macroblock in a B Slice as no DMV is performed by hardware.

Macroblock type conversion rule for an inter macroblock in a B slice

Input			Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	DirectConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
B_Skip_8x8 B_Skip_4x4	DC	DC	DC	n/a	1	1	-	Forced to B_Skip; Hardware will force CBP to zero and also ignore SkipConvDisable control.
B_Skip_8x8 B_Skip_4x4	DC	DC	DC	n/a	0	0	0	REVERSE convert to B_Direct_16x16; Hardware will force CBP to zero and also reverse convert to B_Direct_16x16 when it discovers Skip is not allowed.
B_Direct_16x16_4MVPair/16MVPair	0	0	0	n/a	1	1	-	Converted to B_Skip. Hardware first converts to B_Direct_16x16 and then further to B_Skip if CBP = 0.
B_Direct_16x16_4MVPair/16MVPair	0	0	0	n/a	0	0	0	Converted to B_Direct_16x16. Hardware first converts to B_Direct_16x16 and stop there as it discovers Skip is not

Input			Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	DirectConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
								allowed even CBP=0.
B_Direct_16x16_4MVPair/16MVPair	1	0	0	n/a	DC	0	0	Converted to B_Direct_16x16. Hardware converts to B_Direct_16x16 and stops there even though CBP = 0 as input disallows Skip conversion.
B_Direct_16x16_4MVPair/16MVPair	DC	0	NZ	n/a	DC	0	0	Converted to B_Direct_16x16. Hardware converts to B_Direct_16x16 and stops there because CBP != 0.
B_Direct_16x16_4MVPair/16MVPair	DC	1	DC	n/a	DC	0	16h	Stay as B_8x8. Hardware stays at B_8x8 and codes each sub macroblocks even all are direct.

The internal signal MbAffSkipAllowed is added to deal with a restriction on the frame/field flag (MbFieldFlag) which is unique to MBAFF. MbAffSkipAllowed is always set to 1 in non-MBAFF modes. In MBAFF mode, a macroblock pair may be both skipped only if its MbFieldFlag is the same as its available neighbor macroblock pair A or B if A or B is available (in that order), or is not 0 if A/B are both not available. Otherwise, one of the macroblocks in the pair must be coded.

To reduce the burden on software, PAK hardware handles the above restriction correctly. For the first MB in a pair, MbAffSkipAllowed is always set to 1. Therefore, hardware allows converting the first MB to Skip if skip conversion is enabled. For the second MB in a pair, hardware sets MbAffSkipAllowed to 0 if the following is true:

- The current MB Pair has different MbFieldFlag than its available neighbor A or B if A or B is available, or is not 0 if A/B are both not available
- And the first MB is coded as a SKIP (could be forced or converted)

Otherwise, it sets MbAffSkipAllowed to 1. As MbAffSkipAllowed is to 0 for the above condition, hardware will disallow Skip mode for the second MB. If the input signal forces it to Skip, hardware performs reverse-conversion to code it as P_L0_16x16 or B_Direct_16x16 with CBP = 0 for a macroblock in a P or B Slice. This means that hardware is able to correct the programming mistake by software. If the macroblock is not forced to skip, hardware simply disallows Skip conversion.

Software still has an option to disallow Skip Conversion on a per-MB basis using the MbSkipConvDisable control field in the inline command.

Indirect Data Description

For each macroblock, an ENC-PAK data set consists of two types of data blocks: indirect **MV data block** and **inline MB information**.

The indirect MV data block may be in two modes: **unpackedmode** and **packed-size mode**.

Unpacked Motion Vector Data Block

Unpacked Motion Vector Data Block

In the **unpacked** mode, motion vectors are expanded (or duplicated) to either bidirectional 8x8 8MV major partition format, or bidirectional 4x4 32MV format. Thus either 32 bytes or 128 bytes is assigned to each MB.

Motion Vector block contains motion vectors in an intermediate format that is partially expanded according to the sub- macroblock size. During the expansion, a place that does not contain a motion vector is filled by replicating the relevant motion vector according to the following motion vector replication rules. If the relevant motion vector doesn't exist (for the given L0 or L1), it is zero filled.

Motion Vector Replication Rules:

- Rule #1
    - #1.1: For L0 MV, for any sub-macroblock or sub-partition where there is at least one motion vector
        - If L0 inter prediction exists, the corresponding L0 MV is used
        - Else it must be zero
    - #1.2: For L1 MV, for any sub-macroblock or sub-partition where there is at least one motion vector
        - If L1 inter prediction exists, the corresponding L1 MV is used
        - Else it must be zero

- For a macroblock with a 16x16, 16x8 or 8x16 sub-macroblock, MvSize = 8. The eight MV fields follow Rule #1.
    - The 16x16 is broken down into 4 8x8 sub-macroblocks. The 16x16 MVs (after rule #1) are replicated into all 8x8 blocks.
    - For an 8x16 partition, each 8x16 is broken down into 2 8x8 stacking vertically. The 8x16 MVs (after rule #1) are replicated into both 8x8 blocks.
    - For a 16x8 partition, each 16x8 is broken down into 2 8x8 stacking horizontally. The 16x8 MVs (after rule #1) are replicated into both 8x8 blocks.
- For macroblock with sub-macroblock of 8x8 without minor partition (SubMbShape[0...3] = 0), MvSize = 8, (e.g. mb_type equal to P_8x8, P_8x8ref0, or B_8x8)
    - There is no motion vector replication
- For macroblock with sub-macroblock of 8x8 with at least one minor partition (if any SubMbShape[i] != 0), MvSize = 32, (e.g. mb_type equal to P_8x8, P_8x8ref0, or B_8x8)
    - For an 8x8 sub-partition, the 8x8 MVs (after rule #1) is replicated into all the four 4x4 blocks.
    - For an 4x8 sub-partition within an 8x8 partition, each 4x8 is broken down into 2 4x4 stacking vertically. The 4x8 MVs (after rule #1) are replicated into both 4x4 blocks.
    - For an 8x4 sub-partition within an 8x8 partition, each 8x4 is broken down into 2 4x4 stacking horizontally. The 8x4 MVs (after rule #1) are replicated into both 4x4 blocks.
    - For a 4x4 sub-partition within an 8x8 partition, each 4x4 has its own MVs (after rule #1).

The motion vector(s) for a given sub-macroblock or a sub-partition are uniquely placed in the output message as shown by the non-duplicate fields in Motion Vector duplication by sub-macroblocks for a 16x16 macroblock, whereas the 8x8 column is for 4x(8x8) partition without minor shape and Motion Vector duplication by sub-partitions for the first 8x8 sub-macroblock Y0 if any Y0-Y3 contains minor shape (Y1_ to Y3_ have the same format in W2 to W4).

MV_Yx_L0 and MV_Yx_L1 may be present individually or both. If one is not present, the corresponding field must be zero. Subsequently, the duplicated fields will be zero as well.

Packed-Size Motion Vector Data Block

In the packed case, no redundant motion vectors are sent. So the number of motion vectors sent, as specified by **MvQuantity** is the same as the motion vectors that will be packed (**MvPacked**).

The following tables are for information only. Fields like MvQuantity and MvPacked are not required interface fields.

MbSkipFlag	MbType	Description	Mv Quantity	MvSize	(Minimal MvSize)
1	1	P_Skip_16x16	0	8	1
0	1	BP_L0_16x16	1	8	1

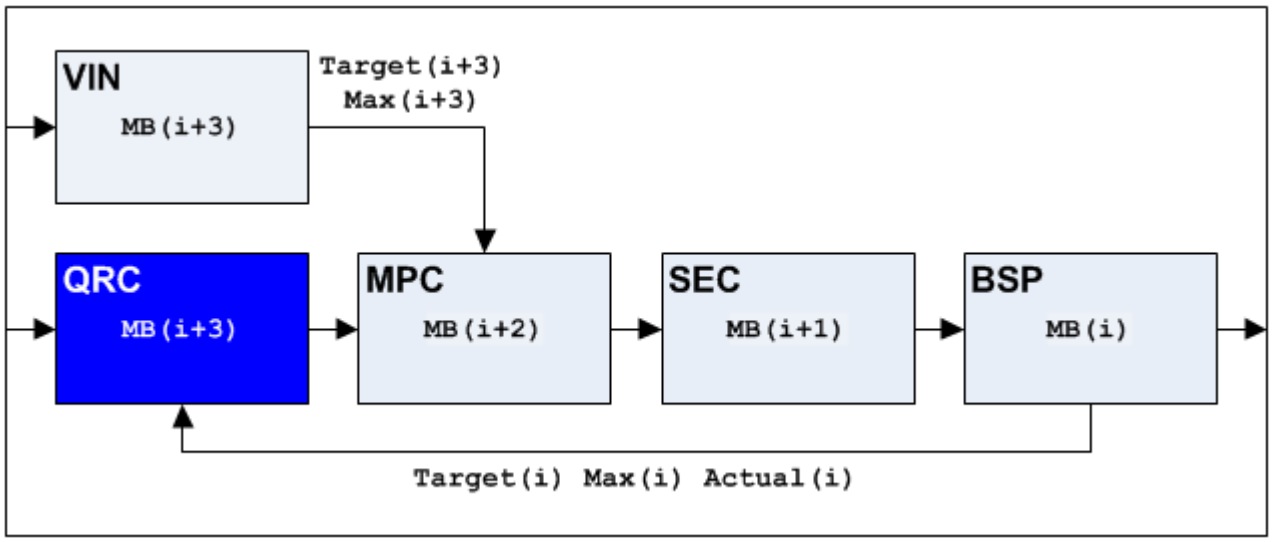
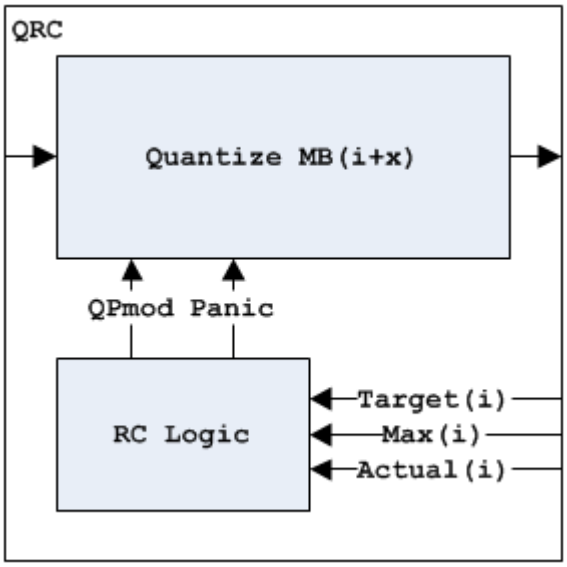
Macroblock Level Rate Control

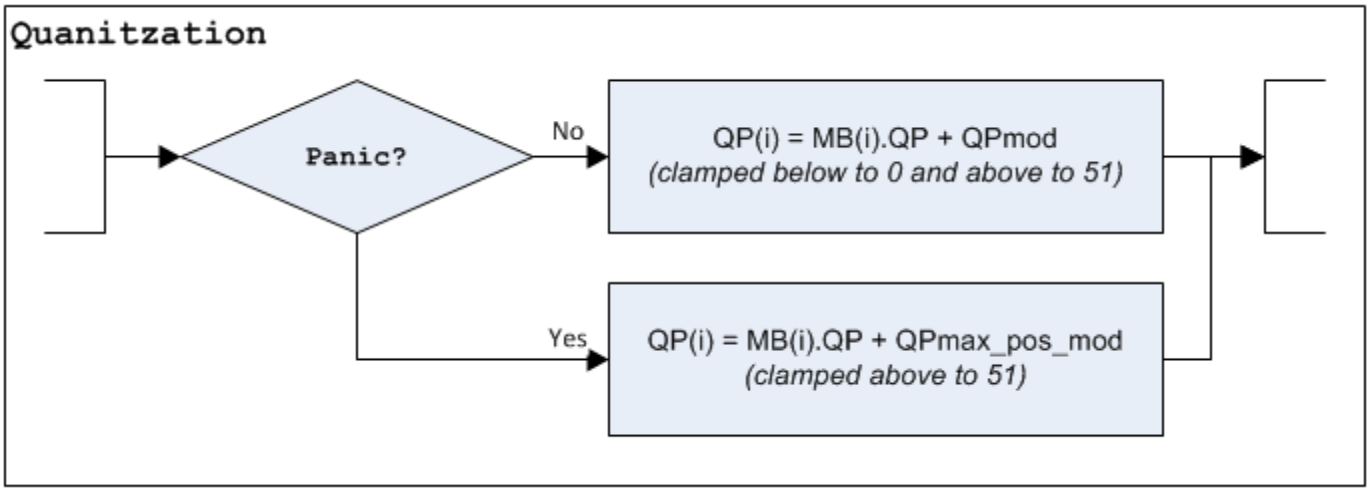
The QRC (Quantization Rate Control) unit receives data from BSP (Bit Serial Packer) and VIN (Video In) and generates adjustments to QP values across macroblocks.



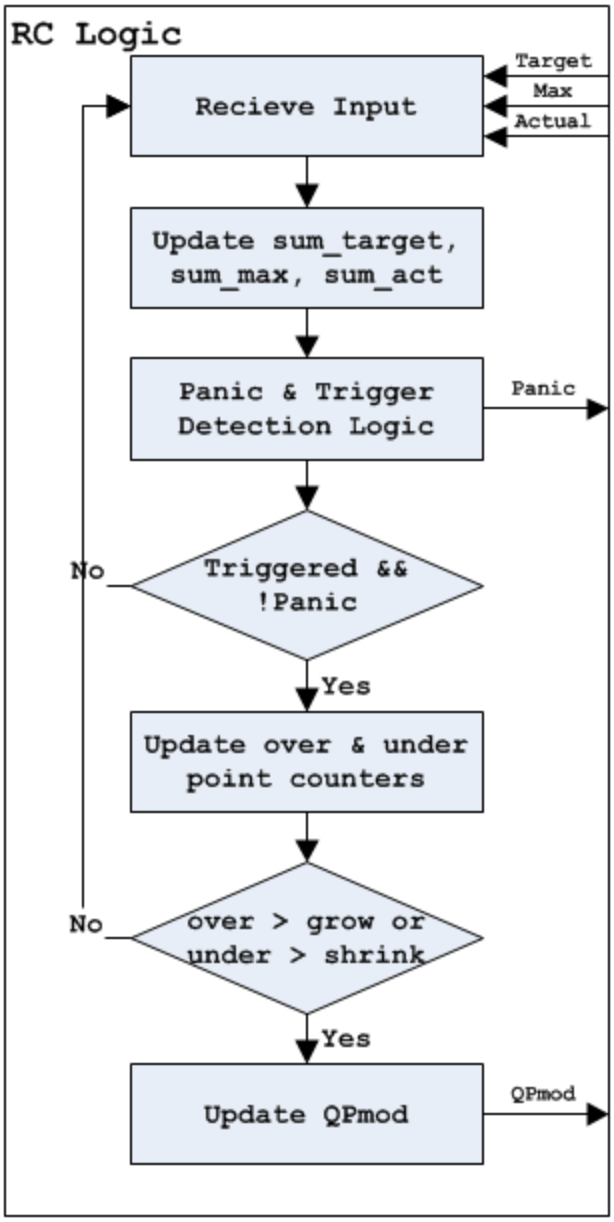
QRC can be logically partitioned into two units as shown below.



Macroblock level rate control is handled by the RC logic and the quantization logic.



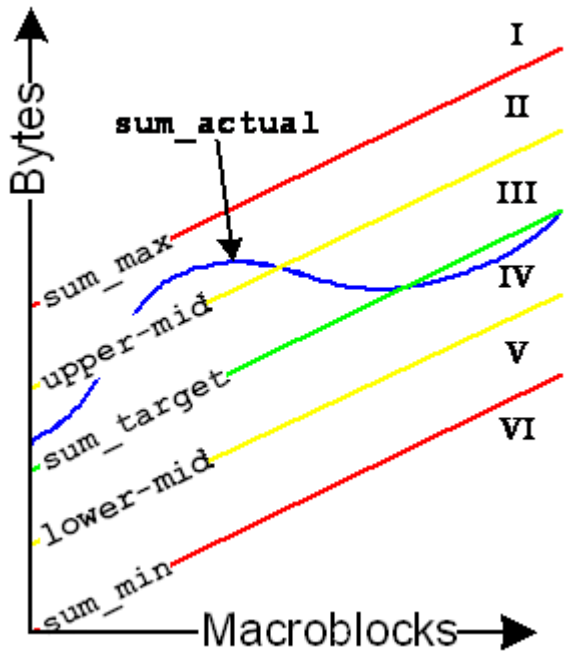
The signals QPmod and panic are generated by the RC logic based on data feedback from BSP. A flowchart of the RC logic is given below.



Theory of Operation Overview

BSP will generate a byte estimate for each macroblock packed. Additionally, the user will specify a target and max size per macroblock. The running sum of these signals (actual, target, max) creates "curves" which are used to identify when QP adjustments are necessary (see figure below). Three more curves are symmetrically generated by QRC (upper_midpt, lower_midpt, sum_min) from target and max. The values of target and max are specified by the user will dictate the shape of these curves.

The difference between sum_actual and sum_target (called 'bytediff') identifies the margin of error between the target and actual sizes. The difference between the current bytediff and the previously calculated bytediff represents the rate of change in this margin over time. The sign of this rate is used to identify if the correction is trending in the appropriate direction (towards bytediff = 0).



QPmod

Each macroblock will have a requested QP (which could vary across macroblocks or remain constant). QPmod is to be added to the QP requested. QPmod will be positive when the target was under-predicted and negative when the target is over-predicted.

QPmod is incremented or decremented when internal counters (called 'over' and 'under') reach tripping points (called 'grow' and 'shrink'). For each MB processed and based on which region (1-6) sum_actual falls in, various amounts of points are added to either counters. If over exceeds grow, QPmod is incremented whereas if under exceeds shrink, QPmod is decremented.

To dampen the effect of repeated changes in the same direction, an increase in resistance for that direction and decrease in resistance for the complementary direction occurs (called 'grow_resistance' and 'shrink_resistance'). This resistance is added to grow or shrink, which then requires more points to trip the next correction in that direction.

The user can specify guard-bands that limit the amount QPmod can be modified. QPmod cannot exceed QPmax_pos_mod or become less than -QPmax_neg_mod_abs.

Triggering

The RC unit begins to modify QPmod occurs only when it is triggered.

Three levels of triggering exist: always, gentle, loose. Always means that RC will be active once sum_actual reaches regions 3 or 4. Gentle will trigger RC once sum_actual reaches regions 2 or 5. Loose waits to trigger RC when sum_actual reaches regions 1 or 6.

RC will deactivate (triggered = false) once sum_actual begins to track sum_target over a series of macroblocks. Specifically, the sign of the rate of change for bytediff is monitored over a window of

macroblocks. When the sum of these signs over the window falls within a tolerance value (called 'stable'), triggered will reset to false.

Panic

When enabled, panic mode will occur whenever sum_actual reaches region 1 and will remain so until sum_actual reaches region 4. When panicking, all macroblocks will be quantized with QP = MB(n).QP + QPmax_pos_mod, clamped to 51.

User Controls

This unit achieves a large flexibility by allowing the user to define various key parameters. At the per-macroblock level, the values of target and max are specified and will create various shapes of curves that sum_actual will be compared against.

Per-slice, the user can specify the triggering sensitivity and the tolerance required to disable the trigger. Additionally, the user can enable panic detection.

The point values assigned to each of the 6 regions are exposed to the user which allow for asymmetrical control for over and under predictions amongst other things. Additionally, the user can specify the initial values of grow and shrink along with the resistance values applied when correction is invoked.

Lastly, the maximum and minimum values for QPmod are also exposed to the user.

AVC Encoder MBAFF Support

1. **Algorithm**

   Prediction of current macroblock motion vector is possible from neighboring macroblocks mbAddrA/mbAddrD/mbAddrB/mbAddrC/mbAddrA+1/mbAddrD+1/mbAddrB+1/mbAddrC+1. The selection of these macroblocks depends on coding type(field/frame) of current macroblock pair and the coding of neighboring macroblock pair.

   Selection of these macroblock pairs is described in detail in following sections.

   1.1 Selection of Top LeftMB pair: The selection of Top Left MB pair depends on coding type of current and also top left macroblock pair.

   1.2 Selection of LeftMB pair: The selection of Left MB pair depends on coding type of current and also left macroblock pair.

   1.3 Selection of Top MB pair: The selection of Top MB pair depends on coding type of current and also top macroblock pair.

   1.4 Selection of Top RightMB pair: The selection of Top Right MB pair depends on coding type of current and also top right macroblock pair.

   1.5 Motion Vector and refIdx Scaling: Motion vectors and reference index of neighboring macroblocks (mbAddrA/mbAddrB/mbAddrC/mbAddrD) should be scaled before using them into prediction equations. Again, the scaling depends on coding type of current and neighboring macroblock pair which is described as follows,

- If the current macroblock is a field macroblock and the macroblock mbAddrN is a frame macroblock ...

```
mvLXN[ 1 ] = mvLXN[ 1 ] / 2 (8-214)
refIdxLXN = refIdxLXN * 2   (8-215)
```

- Otherwise, if the current macroblock is a frame macroblock and the macroblock mbAddrN is a field macroblock ...

```
mvLXN[ 1 ] = mvLXN[ 1 ] * 2 (8-216)
refIdxLXN = refIdxLXN / 2   (8-217)
```

- Otherwise, the vertical motion vector component mvLXN[1] and the reference index refIdxLXN remain unchanged.

MPEG-2

This topic is currently under development.

MPEG2 Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_MPEG2_PIC_STATE

MPEG2 Decoder Commands

These are decoder-only commands. They provide the pointer to the compressed input bitstream to be decoded.

MFD_MPEG2_BSD_OBJECT

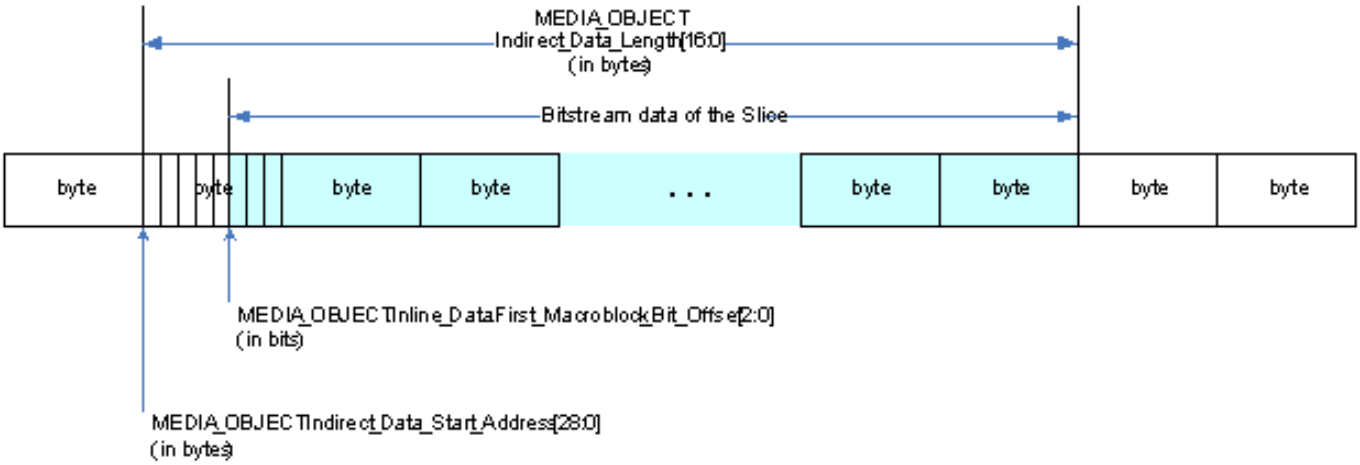
MFD_MPE2_BSD_OJBECT Inline Data Description

Indirect Data Description

The indirect data start address in MFD_MPEG2_BSD_OBJECT specifies the starting Graphics Memory address of the bitstream data that follows the slice header. It provides the byte address for the first macroblock of the slice. Together with the First Macroblock Bit Offset field in the inline data, it provides the bit location of the macroblock within the compressed bitstream.

The indirect data length in MFD_MPEG2_BSD_OBJECT provides the length in bytes of the bitstream data for this slice. It includes the first byte of the first macroblock and the last **non-zero** byte of the last macroblock in the slice. Specifically, the zero-padding bytes (if present) and the next start-code are excluded. Hardware ignores the contents after the last non-zero byte. The image below, Indirect data buffer for a slice illustrates these parameters for a slice data.

Indirect data buffer for a slice



MPEG2 Encoder PAK Commands

The MFC_MPEG2_PAK_INSERT_OBJECT Command is identical to the MFC_AVC_PAK_INSERT_OBJECT command as described in this document.

The MFC_MPEG2_STITCH_OBJECT Command is identical as MFC_AVC_STITCH_OBJECT command as described in this document.

MFC_MPEG2_SLICEGROUP_STATE

MFC_MPEG2_PAK_OBJECT

PAK Object Inline Data Description - MPEG-2

The Inline Data includes all the required MB encoding states, constitute part of the Slice Data syntax elements, MB Header syntax elements and their derivatives. It provides information for the following operations:

1. Forward and Inverse Transform
2. Forward and Inverse Quantization
3. Advanced Rate Control (QRC)
4. MB Parameter Construction (MPC)
5. VLC encoding
6. Bit stream packing
7. Internal error handling

These state/parameter values may subject to change on a per-MB basis, and must be provided in each MFC_MPEG2_PAK_OBJECT command. The values set for these variables are retained internally, until they are reset by hardware Asynchronous Reset or changed by the next MFC_MPEG2_PAK_OBJECT command.

The inline data has been designed to match AVC MB structure for efficient transcoding.

Current MB [x,y] address is not sent, it is assumed that the H/W will keep track of the MB count and current MB position internally.

DWord	Bit	Description
1	31:27	Reserved: MBZ
	22-20	**MvFormat (Motion Vector Size)**. This field specifies the size and format of the input motion vectors. This field is reserved (MBZ) when the **IntraMbFlag** = 1. The valid encodings are: **011 = Unpacked: Two motion vector pairs** Others are reserved. *(The following encodings are intended for other formats:* *001 = 1MV: one 16x16 motion vector* *010 = 2MV: One 16x16 motion vector pair* *011 = 4MV: Four 8x8 motion vectors, or Two 16x8 motion vector pairs* *100 = 8MV: Four 8x8 motion vector pairs* *101 = 16MV: 16 4x4 motion vectors* *110 = 32MV: 16 4x4 motion vector pairs* *111 = Packed, number of MVs is given by **packedMvNum**.)*
	19	**CbpDcY.** This field specifies if the Luma DC coded. Must be 1 for MPEG-2.
	18	**CbpDcU.** This field specifies if the Chroma Cb DC coded. Must be 1 for MPEG-2**.**
	17	**CbpDcV.** This field specifies if the Chroma Cb DC coded. Must be 1 for MPEG-2**.**
	16	Reserved: MBZ
	15	**TransformFlag** Used to indicate transformation type for MPEG-2. 0 = Frame DCT transformation 1 = Field DCT transformation
	14	**FieldMbFlag** For MPEG-2, this flag is set to 1 if either the picture is in field type or the MB is INTER of field type, i.e. split into two 16x8 field blocks.

DWord	Bit	Description
	13	**IntraMbFlag** This field specifies whether the current macroblock is an Intra (I) macroblock. For I-picture MB (IntraPicFlag =1), this field must be set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes). 0: INTER (inter macroblock) 1: INTRA (intra macroblock)
	12:8	**MbType** This field is encoded to match with the best macroblock mode determined as described in the next section. It follows an unified encoding for inter and intra macroblocks according to MFX Encoding reference as shown in Figure A.
	7:3	Reserved : MBZ
	2	**SkipMbFlag** By setting it to 1, this field forces an inter macroblock to be encoded as a skipped macroblock. It is equivalent to mb_skip_flag in AVS spec, Hardware honors input MVs for motion prediction and forces CBP to zero. By setting it to 0, an inter macroblock will be coded as a normal inter macroblock. The macroblock may still be coded as a skipped macroblock, according to the macroblock type conversion rules described in the later sub sections. This field can only be set to 1 for certain values of MbType. See details later. This field is only valid for an inter macroblock. Hardware ignores this field for an intra macroblock. 0 = not a skipped macroblock 1 = is coded as a skipped macroblock **Note:** When this flag is set to 1, the correct MVs are assumed for HW decoder to generate decoded reconstruction frame.
	1:0	**InterMbMode** This field is provided to carry redundant information as that encoded in MbType. This field is only valid if **IntraMbFlag** =0, otherwise, it is ignored by hardware.
2	31:16	**MbYCnt (Vertical Origin).** This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks. Format = U16 in unit of macroblock.
	15:0	**MbXCnt (Horizontal Origin).** This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks.

DWord	Bit	Description
		Format = U16 in unit of macroblock.
3	31:24	**MaxSizeInWord** PAK should not exceed this budget accumulatively, otherwise it will trickle the PANIC mode.
	23:16	**TargetSizeInWord** PAK should use this budget accumulatively to decide if it needs to limit the number of non-zero coefficients.
	15:13	**MBZ**
	12:0	**Cbp -** Coded Block Pattern. This field specifies whether blocks are present or not. Format = 6-bit mask (or 8-bit, & 12-bit, for 422 and 444). Bit 11: Y0Bit 10: Y1Bit 9: Y2Bit 8: Y3 Bit 7: Cb4Bit 6: Cr5Bits 0-5: MBZ
4	31	**LastMbInSlice -** the last MB in a slice.
	30	**FirstMbInSlice -** the first slice in a slice, it requires slice header insertion.
	29:28	**MBZ**
	27	**EnableCoeffClamp** 1 = the magnitude of coefficients of the current MB will be clamped based on the clamping matrix after quantization 0 = no clamping
	26	**LastMbInSG** 1 - the current MB is the last MB in the current slice group.
	25	**MbSkipConvDisable** This is a per-MB level control to enable and disable skip conversion. This field is ORed with SkipConvDisable field. This field is only valid for a P or B slice. It must be zero for other slice types. Rules are provided in Macroblock Type Conversion Rules. 0 - Enable skip type conversion for the current macroblock 1 - Disable skip type conversion for the current macroblock
	24	**FirstMbInSG** 1 - the current MB is the last MB in the current slice group.

DWord	Bit	Description
		if Mv[1][1] n/a: it MUST be set to the same value as Mv[1][0]

The mapping between MPEG-2 spec and MfxMbCode can be achieved according to the following:

1) Renamed variables with identical meaning:

MPEG-2 Spec	MFX API	Value
macroblock_quant	**MbQuantPresent**	0 or 1
macroblock_intra	**IntraMbFlag**	0 or 1
dct_type	**Transform8x8Flag**	0 or 1
macroblock_pattern	**Cbp8x8**	remapped

2) Macroblock type remapping:

		PRM Entry					MPEG-2 Spec				
Frame Type	Mb Type	Intra Mb Flag	Skip Mb Flag	Mb Type 5Bits	Field Mb Flag	Inter Mb Mode	macroblock_intra	motion_type_bit0	motion_type_bit1	motion_forward	motion_backward
IPB	Intra	1	0	1Ah	0/1	-	1	-	-	-	-
P **B** B	Skip	0	1	01h 02h 03h	0/1	0	0	-	-	1 0 1	0 1 1
P	0-MV*	0	0	01h	0/1	0	0	-	-	0	0
P Frame	Frame type	0	0	01h	0	0	0	0	1	1	0
P Frame	Field type	0	0	04h	1	1	0	1	0	1	0
P Frame	dual prime	0	0	19h	0	0	0	1	1	1	0

		PRM Entry					MPEG-2 Spec				
Frame Type	Mb Type	Intra Mb Flag	Skip Mb Flag	Mb Type 5Bits	Field Mb Flag	Inter Mb Mode	macroblock_intra	motion_type_bit0	motion_type_bit1	motion_forward	motion_backward
P Field	One 16x16	0	0	01h	1	0	0	1	0	1	0
P Field	Two 16x8	0	0	04h	1	1	0	0	1	1	0
P Field	dual prime	0	0	19h	1	0	0	1	1	1	0
B Frame	Frame type	0	0	01h 02h 03h	0	0	0	0	1	1 0 1	0 1 1
B Frame	Field type	0	0	04h 06h 14h	1	1	0	1	0	1 0 1	0 1 1
B Field	One 16x16	0	0	01h 02h 03h	1	0	0	1	0	1 0 1	0 1 1
B Field	Two 16x8	0	0	04h 06h 14h	1	1	0	0	1	1 0 1	0 1 1

- Notice that there is no special way to indicate 0 motion vector case for P frame. It is for PAK to handle internally by checking up the motion vector values.
- Notice also, the MbType5bits is adapted from AVC DXVA macroblock types. It may seems awkward from MPEG-2 perspective, but provides a common VME interface for us for simpler HW design and help the advanced transcoding solution.

    }
}
```

Video Codec VC-1

This section describes support for the open video compression standard VC-1, which is the common name for SMPTE 421M approved on April 3, 2006.

VC1 Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_VC1_PRED_PIPE_STATE

MFX_VC1_DIRECTMODE_STATE

VC1 Decoder Commands

These are decoder-only commands. They provide the pointer to the compressed input bitstream to be decoded.

MFD_VC1_LONG_PIC_STATE

AltPQuantConfig and **AltPQuantEdgeMask** are derived based on the following variables: *DQUANT*, *DQUANTFRM*, *DQPROFILE*, *DQSBEDGE*, *DQDBEDGE*, and *DQBILEVEL* defined in the VC1 standard, as shown in the following table.

Definition of AltPQuantConfig and AltPQuantEdgeMask

Inputs						Outputs		Description
DQUANT	DQUANT FRM	DQ PROFILE	DQDB EDGE	DQSB EDGE	DQBI LEVEL	AltPQuant Config	AltPQuant EdgeMask	
0	-	-	-	-	-	00b	0000b	No **AltPQuant**
1	0	-	-	-	-	00b	0000b	No **AltPQuant**
1	1	11b	-	-	0	10b	0000b	All MBs are different with *MQDIFF* and *ABSMQ*
1	1	11b	-	-	1	11b	0000b	All MBs may switch with 1-bit *MQDIFF*
2	-	-	-	-	-	01b	1111b	All edge MBs
1	1	00b	-	-	-	01b	1111b	All edge MBs
1	1	01b	00b	-	-	01b	0011b	Left and top MBs
1	1	01b	01b	-	-	01b	0110b	Top and right MBs
1	1	01b	10b	-	-	01b	1100b	Right and bottom MBs
1	1	01b	11b	-	-	01b	1001b	Bottom and left MBs
1	1	10b	-	00b	-	01b	0001b	Left MBs
1	1	10b	-	01b	-	01b	0010b	Top MBs
1	1	10b	-	10b	-	01b	0100b	Right MBs
1	1	10b	-	11b	-	01b	1000b	Bottom MBs

MFD_VC1_SHORT_PIC_STATE

Intel HW does not use the MVMODE and MVMODE2 provided at the revised DXVA2 VC1 VLD interface, instead, HW will decode them directly from the bitstream picture header.

MFD_VC1_BSD_OBJECT

For VC1, a slice/picture is always started with MB x position equal to 0. Hence, no need to include in the Object Command.

Handling Emulation Bytes

In general, VC1 BSD unit is capable of handling emulation prevention bytes. However, there is a corner case that requires host software's intervention. Host software needs to overwrite the emulation byte if it overlaps the macroblock layer decode and there is not enough information for the hardware to detect the emulation byte.

The emulation bytes might have an overlap between the picture states and the first macroblock data. If the emulation bytes are 0x00 **0x000x03** 0x00 and the macroblock data starts in the middle of byte1 (**0x00**), then the host software needs to overwrite the **0x03** byte location with the previous byte (**0x00**) and change the byte offset accordingly. The hardware wouldn't know what the 1st byte was and will miss this **0x03** removal.

JPEG and MJPEG

JPEG Decoder Commands

Following are JPEG Decoder Commands:

MFD_JPEG_BSD_OBJECT

MFX_JPEG_PIC_STATE command is used for both encoding and decoding. Note the duplicate bits and the "Exists If" rows that specify what the bits represent for Encoder and Decoder.

MFX_JPEG_PIC_STATE

For JPEG decoding, the following program note is informative.

For **Rotation**, it is important to note that rotation of 90 or 270 degrees also requires exchanging **FrameWidthInBlksMinus1** with **FrameHeightInBlksMinus1** in the command. In addition, the rotation of 90 or 270 degrees also requires transportation of the quantization matrix will be transposed into the position (y, x).

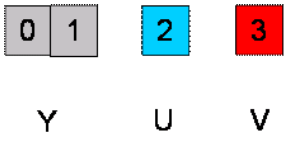
Chroma type is determined by the values of horizontal and vertical sampling factors of the components (*Hi* and Vi where *i* is a component id) in the Frame header as shown in the following table.

	H1	H2	H3	V1	V2	V3
0: YUV400	r	Not available	Not available	r	Not available	Not available
1: YUV420	2	1	1	2	1	1
2: YUV422H_2Y	2	1	1	1	1	1
3: YUV444	1	1	1	1	1	1
4: YUV411	4	1	1	1	1	1
5: YUV422V_2Y	1	1	1	2	1	1
6: YUV422H_4Y	2	1	1	2	2	2
7: YUV422V_4Y	2	2	2	2	1	1

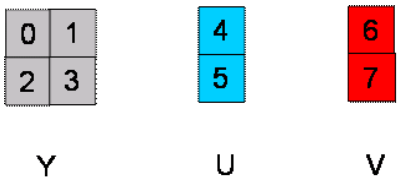
For YUV400, the value of *V1* can be 1, 2, or 3 and will be same as the value of *H1*, and the Minimum coded unit (MCU) is one 8x8 block. For the other chroma formats, if non-interleaved data, the MCU is one 8x8 block. For interleaved data, the MCU is the sequence of block units defined by the sampling factors of the components.

For example, the following figures show the MCU structures of interleaved data and the decoding order of blocks in the MCU:

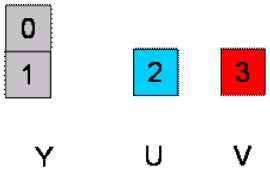
422H_2Y



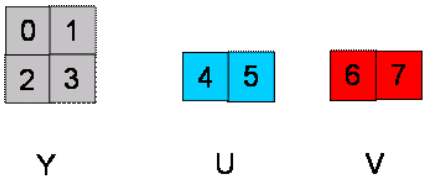
422H_4Y



422V_2Y

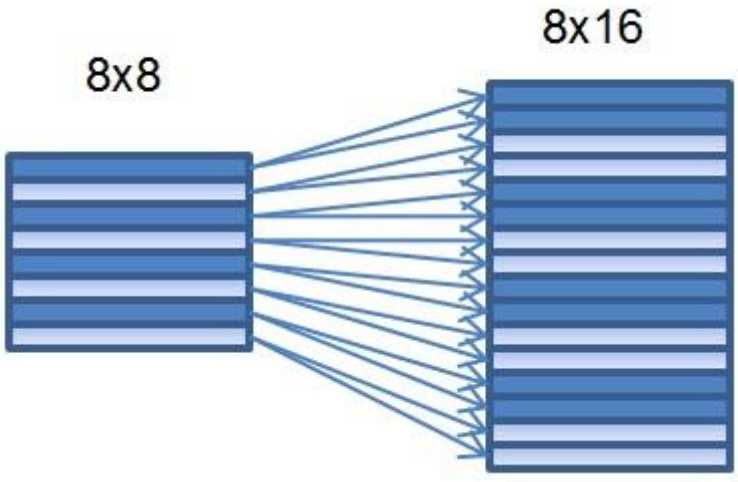


422V_4Y



If picture width *X* in the Frame header is not a multiple of 8, the decoding process needs to extend the number of columns to complete the right-most sample blocks. If the component is to be interleaved, the decoding process needs to extend the number of samples by one or more additional blocks so that the number of blocks is an integer multiple of *Hi*. In other words, "The number of blocks in width" in the table should be an integer multiple of (8x*H1*). Similarly, if picture height *Y* in the Frame header is not a multiple of 8, the decoding process needs to extend the number of lines to complete bottom-most block-row. If the component is to be interleaved, the decoding process also needs to extend the number of lines by one or more additional block-rows so that the number of block-row is an integer multiple of (8x*V1*). For example, if non-interleaved YUV411 with *X*=270, then "The number of blocks in width" shall be (270 + 7) / 8 = 34, where "/" is integer division. Therefore, **FrameWidthInBlksMinus1** is set to 33. However, for interleaved data, "The number of blocks in width" shall be ((270 + 31) / 32) x 4 = 36. Therefore, **FrameWidthInBlksMinus1** is set to 35.

VertUpSamplingEnb is used to convert an input chroma420 to an output chroma422 in the surface format of YUY2 or UYVY. To enable this flag, the input should be interleaved Scan, InputFormatYUV should be set to YUV420, and OutputFormatYUV should be set to YUY2 or UYVY. Vertical 2:1 up-sampling is only applied to chroma blocks where each line of 8x8 block pixels is replicated to make 8x16 U/V blocks. For example:



VertDownSamplingEnb is used to convert an input chroma422 to an output chroma420 in the surface format NV12. To enable this flag, the input should be interleaved Scan, InputFormatYUV should be set to YUV422H_2Y or YUV422H_4Y, and OutputFormatYUV should be set to NV12. Combined with AvgDownSampling flag, the following table and figures show the down-sampling methods.

VertDownSamplingEnb	AvgDownSampling	Down-Sampling Methods
0	0 or 1	No down-sampling.
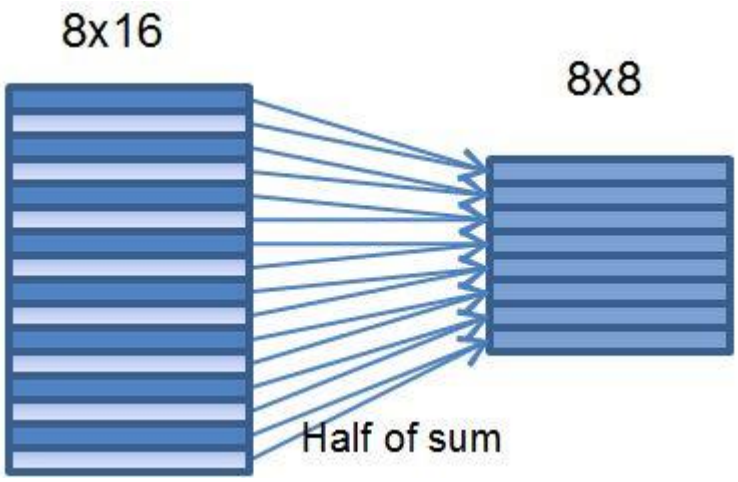
1	0	Drop every other line: 1	1	Average vertically neighboring two pixels:

VertDownSamplingEnb	AvgDownSampling	Down-Sampling Methods
		


The recent history forJPEG Decoder Commands are described in the following:

- If the InputFormat is YUV400 or YUV444 or YUV411, then output cannot be NV12, YUY2 or UYVY, it has to be planar. But for 420 and 422 InputFormat, there's a choice of having Planar, NV12, YUY2 or UYVY OutputFormat. And the surface state should be programmed accordingly.
- Refer "Output Format YUV" field for more details.

MFX_JPEG_HUFF_TABLE_STATE

JPEG Encoder Commands

JPEG Encoder Command Sequence:

Commands
MFX_PIPE_MODE_SELECT
MFX_SURFACE_STATE
MFX_PIPE_BUF_ADDR_STATE
MFX_IND_OBJ_BASE_ADDR_STATE
MFX_JPEG_PIC_STATE
MFX_FQM_STATE (One each for Luma, CB and CR)
MFC_JPEG_ HUFF_TABLE_STATE(Huffman table 0 and 1 need two commands to be issued).
MFC_JPEG_SCAN_OBJECT
MFX_PAK_INSERT_OBJECT (Multiple commands can be given based on the need)

Following are JPEG Encoder Commands:

MFX_JPEG_PIC_STATE command is used for both encoding and decoding. Note the duplicate bits and the "Exists If" rows that specify what the bits represent for Encoder and Decoder.

MFX_JPEG_PIC_STATE

Programming Note: For completion of partial MCUs in JPEG encoding, it is important to note the following:

If the image's dimensions are not an exact multiple of the MCU size, the encoded data should include padding to round up to the next complete MCU, which is called completion of partial MCU. If the number of lines is not aligned with MCU structure (not a multiple of MCU size, i.e. 8, 16, 32), the encoding process needs to extend the number of lines to complete the bottom-most MCU-row. Similarly, if the number of samples per line is not aligned with MCU structure, the encoding process needs to extend the number of columns to complete the right-most sample MCUs. JPEG standard recommends that any incomplete MCUs be completed by replication of the right-most column and the bottom line of each component Y, U, and V.

The following equations are used to set the command for encoding partial MCUs.

FrameWidthInBlksMinus1 = (((*X* + (*H*1 *8 -1)) / (*H*1 *8)) * *H*1) - 1

FrameHeightInBlksMinus1 = (((*Y* + (*V*1*8 -1)) / (*V*1*8)) * *V*1) - 1

```
For YUV400,
    PixelsInHoriLastMCU = X % 8
    PixelsInVertLastMCU = Y % 8

For YUV420,
    PixelsInHoriLastMCU = X % 16 if X % 2 = 0, ((X % 16) + 1) % 16 if X % 2 = 1
    PixelsInVertLastMCU = Y % 16 if Y % 2 = 0, ((Y % 16) + 1) % 16 if Y % 2 = 1

For YUV422H_2Y,
    PixelsInHoriLastMCU = X % 16 if X % 2 = 0, ((X % 16) + 1) % 16 if X % 2 = 1
    PixelsInVertLastMCU = Y % 8

    X: the number of samples per line in Y-image

    Y: the number of lines in Y-image

    H1: horizontal sampling factor of Y-image in the Frame header

    V1:  vertical sampling factor of Y-image in the Frame header
```

Note that PixelsInHoriLastMCU=0 does not mean the num of pixels in the right-most MCUs = 0, but does mean that the right-most MCUs are fully filled with pixels, i.e., not a partial MCU.

For example, for input image dimension 17x26 pixels and an interleaved Scan, the following equations and the table show how to set the command for each OutputMcuStructure.

	YUV400	YUV420	YUV422H_2Y
MCU size of Y	8x8	16x16	16x8
MCU size of U and V	8x8	8x8	8x8
*H*1 and *V*1	1, 1	2, 2	2, 1
FrameWidthInBlksMinus1	2	3	3
FrameHeightInBlksMinus1	3	3	3
PixelsInHoriLastMCU	1	2	2

	YUV400	YUV420	YUV422H_2Y
PixelsInVertLastMCU	2	10	2

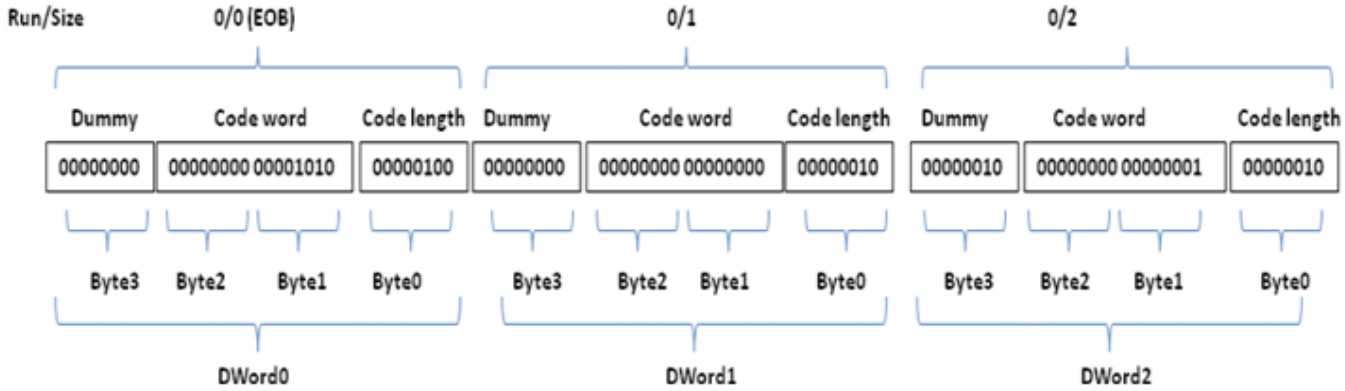
MFC_JPEG_SCAN_OBJECT

The JPEG standard Table K.5 shows the real table of code length and code word as follows:

MFC_JPEG_ HUFF_TABLE_STATE

Run/Size	Code length	Code word
0/0 (EOB)	4	1010
0/1	2	00
0/2	2	01
0/3	3	100
0/4	4	1011
0/5	5	11010
0/6	7	1111000
0/7	8	11111000
0/8	10	1111110110
0/9	16	1111111110000010
0/A	16	1111111110000011

It is not necessary to send Run/size in the command as driver will send the increasing order of run/size. Each symbol aligns to a DWord with the following byte structure. Each DWord (a group of 4 bytes) contains Byte0 for Code length, Byte1 and Byte2 for Code word, and Byte3 for dummy.



Driver will program to always send 12 pairs of Code length and Code Word in DC coefficient table and 162 pairs in AC coefficient table. When a Huffman table contains valid full entries of Run/Size, all the Code word and Code length will not be zero. If a Huffman table is customized or optimized, the table can contain smaller set of Code length and Code Word, i.e., the number of entries of the real Huffman table will be less than 12 for DC, or less than 162 for AC. For the customized Huffman table, driver will set the missing entry (Run/Size) to Code length = 0 and Code word = 0.

MFX_PAK_INSERT_OBJECT

More Decoder and Encoder

MFD IT Mode Decode Commands

These are decoder-only commands to support the IT-mode specified in DXVA interface.

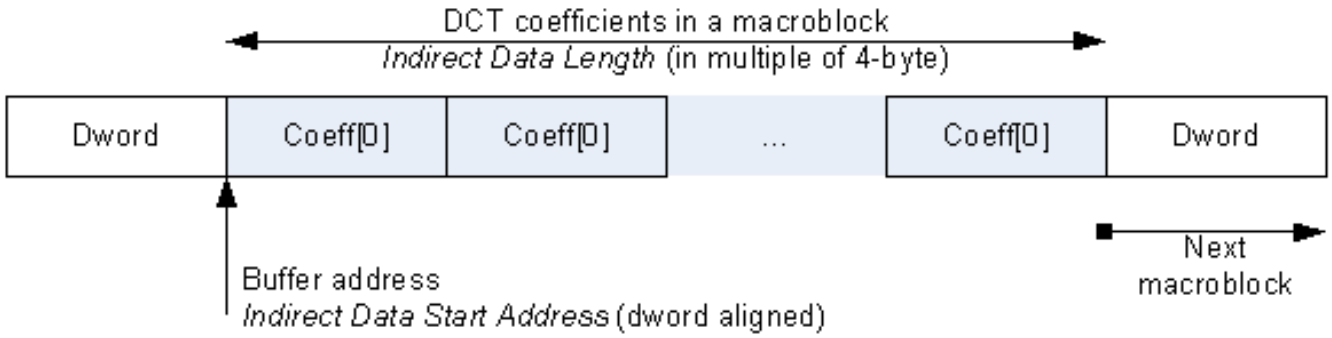
MFD_IT_OBJECT

Common Indirect IT-COEFF Data Structure

Transform-domain residual data block in AVC-IT, VC1-IT and MPEG2-IT mode follows the same data structure.

The indirect IT-COEFF data start address in MFD_IT_OBJECT command specifies the doubleword aligned address of the first non-zero DCT coefficient of the first block of the macroblock. Only the non-zero coefficients are present in the data buffer and they are packed in the 8x8 block sequence of Y0, Y1, Y2, Y3, Cb4 and Cr5, as shown in Structure of the IDCT Compressed Data Buffer. When an 8x8 block is further subdivided into 4x4 subblocks, the coefficients, if present, are organized in the subblock order. The smallest subblock division is referred to as a **transform block**. The indirect IT-COEFF data length in the command includes all the non-zero coefficients for the macroblock. It must be doubleword aligned.

Structure of the IDCT Compressed Data Buffer



Each non-zero coefficient in the indirect data buffer is contained in a doubleword-size data structure consisting of the coefficient index, end of block (EOB) flag and the fixed-point coefficient value in 2's compliment form. As shown in Structure of a transform-domain residue unit, *index* is the row major 'raster' index of the coefficient **within a transform block** (*please note that it is not converted to 8x8 block basis*). A coefficient is a 16-bit value in 2's complement.

Structure of a transform-domain residue unit

DWord	Bit	Description
0	31:16	**Transform-Domain Residual (coefficient) Value.** This field contains the value of the non-zero transform-domain residual data in 2's compliment.
	15:7	Reserved: MBZ
	6:1	**Index.** This field specifies the raster-scan address (raw address) of the coefficient within the transform block. For a coefficient at Cartesian location (row, column) = (y, x) in a transform block of width W, Index is equal to (y * W + x). For example, coefficient at location (row, column) = (0, 0) in a 4x4 transform block has an index of 0; that at (2, 3) has an index of 2*4 + 3 = 11. The valid range of this field depends on the size of the transform block. Format = U6 Range = [0, 63]
	0	**EOB (End of Block).** This field indicates whether the transform-domain residue is the last one of the current transform block.

Allowed transform block dimensions per coding standard

Transform Block Dimension	AVC	VC1	MPEG2
8x8	Yes	Yes	Yes
8x4	No	Yes	No
4x8	No	Yes	No
4x4	Yes	Yes	No

For AVC, there is intra16x16 mode, in which the DC Luma coefficients of all 4x4 sub-blocks within the current MB are sent separately in its own 4x4 Luma block. As such, only 15 coefficients remains in each of the 16 4x4 Luma blocks.

Inline Data Description in AVC-IT Mode

The Inline Data includes all the required MB decoding states, extracted primarily from the Slice Data, MB Header and their derivatives. It provides information for the following operations:

1. Inverse Quantization
2. Inverse Transform
3. Intra and inter-Prediction decoding operations
4. Internal error handling

IT Mode supports only packed MV data as specified in the DXVA spec.

These state/parameter values may subject to change on a per-MB basis, and must be provided in each MFD_IT_OBJECT command. The values set for these variables are retained internally, until they are reset by hardware Asynchronous Reset or changed by the next MFC_AVC_PAK_OBJECT command.

The inline data has been designed to match the DXVA 2.0, with the exception of the starting byte (DW0:0-7) and the ending dword (DW7:0-31).

The Deblocker Filter Control flags (FilterInternalEdgesFlag, FilterTopMbEdgeFlag and FilterLeftMbEdgesFlag) are generated by H/W, which are depending on MbaffFrameFlag, CurrMbAddr, PicWidthInMbs and disable_deblocking_filter_idc states.

Current MB [x,y] address is not sent, it is assumed that the H/W will keep track of the MB count and current MB position internally.

DWord	Bit	Description
0	31:24	**MvQuantity** Specify the number of MVs (in unit of motion vector, 4 bytes each) to be fetched for motion compensation operation. Decoder IT mode only supports packed MV format (DXVA). This field specifies the exact number of MVs present for the current MB. For a P-Skip MB, there is still 1 MV being sent (Skip MV is sent explicitly); for a B-Direct/Skip MB, there are 2 MVs being sent. For an Intra-MB, MvQuantity is set to 0. MvQuantity = 0, signifies there is no MV indirect data for the current MB. This field must be set in consistent with **Indirect MV Data Length**, so as not to exceed its bound Unsigned.
	23:20	Reserved MBZ (DXVA)
	19	**DcBlockCodedYFlag** 1 - the 4x4 DC-only Luma sub-block of the Intra16x16 coded MB is present; it is still possible that all DC coefficients are zero. 0 - no 4x4 DC-only Luma sub-block is present; either not in Intra16x16 MB mode or all DC coefficients are zero.
	18	**DcBlockCodedCbFlag** For 4:2:0 case : 1 - the 2x2 DC-only Chroma Cb sub-block of all coded MB (any type) is present; it is still possible that all DC coefficients are zero. 0 - no 2x2 DC-only Chroma Cb sub-block is present; all DC coefficients are zero.
	17	**DcBlockCodedCrFlag**

DWord	Bit	Description
		For 4:2:0 case : 1 - the 2x2 DC-only Chroma Cr sub-block of all coded MB (any type) is present; it is still possible that all DC coefficients are zero. 0 - no 2x2 DC-only Chroma Cr sub-block is present; all DC coefficients are zero.
	16	Reserved MBZ (DXVA)
	15	**Transform8x8Flag** 0: indicates the current MB is coded with 4x4 transform and therefore the luma residuals are presented in 4x4 blocks. 1: indicates the current MB is coded with 8x8 transform and therefore the luma residuals are presented in 8x8 blocks. Same as the transform_szie_8x8_flag syntax element in AVC spec.
	14	**MbFieldFlag** This field specifies whether current macroblock is coded as a field or frame macroblock in MBAFF mode. 1 = Field macroblock 0 = Frame macroblock This field is exactly the same as FIELD_PIC_FLAG syntax element in non-MBAFF mode. Same as the mb_field_decoding_flag syntax element in AVC spec.
	13	**IntraMbFlag** This field specifies whether the current macroblock is an Intra (I) macroblock. 0 - not an intra MB 1 - is an intra MB I_PCM is considered as Intra MB. For I-picture MB (IntraPicFlag =1), this field must set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes).
	12:8	**MbType** This field carries the Macroblock Type. The meaning depends on IntraMbFlag. If IntraMbFlag is 1, this field is the intra macroblock type as defined in MbType definition for Intra Macroblock . If IntraMbFlag is 0, this field is the inter macroblock type as defined in the first two columns of MbType definition for Inter Macroblock (and MbSkipflag = 0). All macroblock types in a P Slice are mapped into the corresponding types in a B Slice. Skip and Direct modes are converted into its corresponding processing modes.

<table>
<tr><th>DWord</th><th>Bit</th><th>Description</th></tr>
<tr><td></td><td></td><td>Programming note: It is exactly matched with that of DXVA 2.0.</td></tr>
<tr><td></td><td>7</td><td>FieldMbPolarityFlag
This field indicates the field polarity of the current macroblock.
Within a MbAff frame picture, this field may be different per macroblock and is set to 1 only for the second macroblock in a MbAff pair if FieldMbFlag is set. Otherwise, it is set to 0.
Within a field picture, this field is set to 1 if the current picture is the bottom field picture. Otherwise, it is set to 0. It is a constant for the whole field picture.
This field is only valid for MBAFF frame picture. It is reserved and set to 0 for a progressive frame picture or a field picture.
0 = Current macroblock is a field macroblock from the top field (first in a MBAFF pair)
1 = Current macroblock is a field macroblock from the bottom field (second in a MBAFF pair)</td></tr>
<tr><td></td><td>6</td><td>IsLastMB
1 - the current MB is the last MB in the current Slice
0 - the current MB is not the last MB in the current Slice</td></tr>
<tr><td></td><td>5-4</td><td>Reserved MBZ (Intel encoder)</td></tr>
<tr><td></td><td>3:0</td><td>Reserved MBZ (DXVA Decoder)</td></tr>
<tr><td>1</td><td>31:16</td><td>CbpY[bit 15:0] (Coded Block Pattern Y)
For 4x4 sub-block (when Transform8x8flag = 0 or in intra16x16) :
16-bit cbp, one bit for each 4x4 Luma sub-block (not including the DC 4x4 Luma block in intra16x16) in a MB. The 4x4 Luma sub-blocks are numbered as
<table>
<tr><td>blk0</td><td>1</td><td>4</td><td>5</td><td>bit15</td><td>14</td><td>11</td><td>10</td></tr>
<tr><td>blk2</td><td>3</td><td>6</td><td>7</td><td>bit13</td><td>12</td><td>9</td><td>8</td></tr>
<tr><td>blk8</td><td>9</td><td>12</td><td>13</td><td>bit7</td><td>6</td><td>3</td><td>2</td></tr>
<tr><td>blk10</td><td>11</td><td>14</td><td>15</td><td>bit 5</td><td>4</td><td>1</td><td>0</td></tr>
</table>
The cbpY bit assignment is cbpY bit [15 - X] for sub-block_num X.
For 8x8 block (when Transform8x8flag = 1)
Only the lower 4 bits [3:0] are valid; the remaining upper bits [15:4] are ignored. The 8x8 Luma blocks are numbered as
<table>
<tr><td>blk0</td><td>1</td><td>bit3</td><td>2</td></tr>
<tr><td>blk2</td><td>3</td><td>bit1</td><td>0</td></tr>
</table>
The cbpY bit assignment is cbpY bit [3 - X] for block_num X.
0 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero)</td></tr>
</table>

<table>
<tr><th>DWord</th><th>Bit</th><th>Description</th></tr>
<tr><td></td><td></td><td>1 in a bit - indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding).</td></tr>
<tr><td></td><td>15:8</td><td>VertOrigin (Vertical Origin). This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks.

For field macroblock pair in MBAFF frame, the vertical origins for both macroblocks should be set as if they were located in corresponding field pictures. For example, for field macroblock pair originated at (16, 64) pixel location in an MBAFF frame picture, the Vertical Origin for both macroblocks should be set as 2 (macroblocks). Whether the current macroblock is the first/second (top/bottom) in a MBAFF pair is specified by FieldMbPolarityFlag.

The macroblocks with (VertOrigin, HorzOrigin) must be delivered in the strict order as coded in the bitstream (raster order for progressive frame or field pictures and MBAFF pair order for MBAFF pictures). No gap is allowed. Otherwise, hardware behavior is undefined.

Format = U8 in unit of macroblock.</td></tr>
<tr><td></td><td>7:0</td><td>HorzOrigin (Horizontal Origin). This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks.

Format = U8 in unit of macroblock.</td></tr>
<tr><td>2</td><td>31:16</td><td>CbpCr (Coded Block Pattern Cr 4:2:0-only)

Only the lower 4 bits [3:0] are valid; the remaining upper bits [15:4] are ignored (only valid for 4:2:2 and 4:4:4). The 4x4 Chroma Cr sub-blocks are numbered as
<table><tr><td>blk0</td><td>1</td><td>bit3</td><td>2</td></tr><tr><td>blk2</td><td>3</td><td>bit1</td><td>0</td></tr></table>
The cbpCr bit assignment is cbpCr bit [3 - X] for sub-block_num X.

0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero)

1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding).

For monochrome, this field is ignored.</td></tr>
<tr><td></td><td>15-0</td><td>CbpCb (Coded Block Pattern Cb 4:2:0-only)

Only the lower 4 bits [3:0] are valid; the remaining upper bits [15:4] are ignored (only valid for 4:2:2 and 4:4:4). The 4x4 Chroma Cb sub-blocks are numbered as
<table><tr><td>blk0</td><td>1</td><td>bit3</td><td>2</td></tr><tr><td>blk2</td><td>3</td><td>bit1</td><td>0</td></tr></table>
The cbpCb bit assignment is cbpCb bit [3 - X] for sub-block_num X.

</table>

DWord	Bit	Description
		values are zero) 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored.
3	31:24	**Reserved** MBz
	23:16	**QpPrimeCr** Driver is responsible for deriving the QpPrimeCr from QpPrimeY. For 8-bit pixel data, QpCr is the same as QpPrimeCr, and it takes on a value in the range of 0 to 51, positive integer.
	15:8	**QpPrimeCb** Driver is responsible for deriving the QpPrimeCb from QpPrimeY. For 8-bit pixel data, QpCb is the same as QpPrimeCb, and it takes on a value in the range of 0 to 51, positive integer.
	7:0	**QpPrimeY** This is the per-MB QP value specified for the current MB. For 8-bit pixel data, QpY is the same as QpPrimeY, and it takes on a value in the range of 0 to 51, positive integer.
4 to 6	31:0 Each	For intra macroblocks, definition of these fields are specified in Inline data subfields for an Intra Macroblock For inter macroblocks, definition of these fields are specified in Inline data subfields for an Inter Macroblock

Indirect Data Format in AVC-IT Mode

Indirect data in AVC-IT mode consist of Motion Vectors, Transform-domain Residue (Coefficient) and ILDB control data. All three data records have variable size. Size of each Motion Vector record is determined by the MvQuantity value as shown in Indirect MV record size in AVC-IT mode. ILDB control record is fixed at the same size for all MBs in a picture. Coefficient data record is variable size per MB, since it may only consist of non-zero coefficients.

Each MV is represented in 4 bytes, in the form of

- Lower 2 bytes : horizontal MVx component in q-pel units
- Upper 2 bytes : vertical MVy component in q-pel units
- Integer distance is measured in unit of samples in the frame or field grid position.
- Chroma MVs are not sent and are derived in the H/W.

Indirect MV record size in AVC-IT mode

Inline Data Description in VC1-IT Mode

<table>
<tr><th>DWord</th><th>Bits</th><th>Description</th></tr>
<tr><td>+0</td><td>31:28</td><td>MvFieldSelect. A bit-wise representation indicating which field in the reference frame is used as the reference field for current field. It's only used in decoding interlaced pictures.

This field is valid for non-intra macroblock only.

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>28</td><td>Forward predict of current frame/field or TOP field of interlace frame, or block 0 in 4MV mode.</td></tr>
<tr><td>29</td><td>Backward predict of current frame/field or TOP field of interlace frame, or forward predict for block 1 in 4MV mode.</td></tr>
<tr><td>30</td><td>Forward predict of BOTTOM field of interlace frame, or block 2 in 4MV mode.</td></tr>
<tr><td>31</td><td>Backward predict of BOTTOM field of interlace frame, or forward predict for block 3 in 4MV mode.</td></tr>
</table>

Each corresponding bit has the following indication.

0 = The prediction is taken from the top reference field.

1 = The prediction is taken from the bottom reference field.</td></tr>
<tr><td></td><td>27</td><td>Reserved. MBZ</td></tr>
<tr><td></td><td>26</td><td>MvFieldSelectChroma . This field specifies the polarity of reference field for chroma blocks when their motion vector is derived in Motion4MV mode for interlaced (field) picture.

Non-intra macroblock only. This field is derived from MvFieldSelect.

0 = The prediction is taken from the top reference field.</td></tr>
</table>

DWord	Bits	Description
		1 = The prediction is taken from the bottom reference field.
	25:24	**MotionType - Motion Type** For frame picture, a macroblock may only be either 00 or 10. For interlace picture, a macroblock may be of any motion types. It can be 01 if and only if DctType is 1. This field is 00 if and only if IntraMacroblock is 1. 00 = Intra 01 = Field Motion. 10 = Frame Motion or no motion. Others = Reserved.
	23	**Reserved.** MBZ
	22	**MvSwitch.** This field specifies whether the prediction needs to be switched from forward to backward or vice versa for single directional prediction for top and bottom fields of interlace frame B macroblocks. 0 = No directional prediction switch from top field to bottom field 1 = Switch directional prediction from top field to bottom field
	21	**DctType.** This field specifies whether the residual data is coded as field residual or frame residual for interlaced picture. This field can be 1 only if MotionType is 00 (intra) or 01 (field motion). For progressive picture, this field must be set to '0', i.e. all macrobalcoks are frame macroblock. 0 = Frame residual type. 1 = Field residual type.
	20	**OverlapTransform.** This field indicates whether overlap smoothing filter should be performed on I-block boundaries. 0 = No overlap smoothing filter. 1 = Overlap smoothing filter performed.
	19	**Motion4MV.** This field indicates whether current macroblock a progressive P picture uses 4 motion vectors, one for each luminance block. It's only valid for progressive P-picture decoding. Otherwise, it is reserved and MBZ. For example, with MotionForward is 0, this field must also be set to 0. 0 = 1MV-mode. 1 = 4MV-mode.

DWord	Bits	Description
	18	**MotionBackward.** This field specifies whether the backward motion vector is active for B-picture. This field must be 0 if Motion4MV is 1 (no backward motion vector in 4MV-mode). 0 = No backward motion vector. 1 = Use backward motion vector(s).
	17	**MotionForward.** This field specifies whether the forward motion vector is active for P and B pictures. 0 = No forward motion vector. 1 = Use forward motion vector(s).
	16	**IntraMacroblock.** This field specifies if the current macroblock is intra-coded. When set, Coded Block Pattern is ignored and no prediction is performed (i.e., no motion vectors are used). For field motion, this field indicates whether the top field of the macroblock is coded as intra. 0 = Non-intra macroblock. 1 = Intra macroblock.
	15:12	**LumaIntra8x8Flag - Luma Intra 8x8 Flag** This field specifies whether each of the four 8x8 luminance blocks are intra or inter coded when Motion4MV is set to 4MV-Mode. Each bit corresponds to one block. "0" indicates the block is inter coded and '1' indicates the block is intra coded. When Motion4MV is not 4MV-Mode, this field is reserved and MBZ. Bit 15: Y0 Bit 14: Y1 Bit 13: Y2 Bit 12: Y3
	11:6	**CBP - Coded Block Pattern** This field specifies whether the 8x8 residue blocks in the macroblock are present or not. Each bit corresponds to one block. "0" indicates residue block isn't present, "1" indicates residue block is present. Note: For each block in an intra-coded macroblock or an intra-coded block in a P macroblock in 4MV-Mode, the corresponding CBP must be 1. Subsequently, there must be at least one coefficient (this coefficient might be zero) in the indirect data buffer associated with the bock (i.e. residue block must be present). Bit 11: Y0 Bit 10: Y1

DWord	Bits	Description
		Bit 9: Y2 Bit 8: Y3 Bit 7: Cb4 Bit 6: Cr5
	5	**ChromaIntraFlag - Derived Chroma Intra Flag** This field specifies whether the chroma blocks should be treated as intra blocks based on motion vector derivation process in 4MV mode. 0 = Chroma blocks are not coded as intra. 1 = Chroma blocks are coded as intra
	4	**LastRowFlag - Last Row Flag** This field indicates that the current macroblock belongs to the last row of the picture. This field may be used by the kernel to manage pixel output when overlap transform is on. 0 = Not in the last row 1 = In the last row
	3	**LastMBInRow - This field indicates the last MB in row flag.**
	2:0	**Reserved.** MBZ
+1	32:26	**Reserved.** MBZ
	25:24	**OSEdgeMaskChroma** This field contains the overscan edge mask for the Chroma blocks. The left edge masks are hardware and the top edge masks are used by the kernel software. Bit 24: Top edge of block Cb/Cr Bit 25: Left edge of block Cb/Cr
	23:16	**OSEdgeMaskLuma** This field contains the overscan edge mask for the Luma blocks. The left edge masks are hardware and the top edge masks are used by the kernel software. Bit 16: Top edge of block Y0 Bit 17: Top edge of block Y1 Bit 18: Top edge of block Y2 Bit 19: Top edge of block Y3

DWord	Bits	Description
		Bit 20: Left edge of block Y0 Bit 21: Left edge of block Y1 Bit 22: Left edge of block Y2 Bit 23: Left edge of block Y3 *Programming Note: In order to create 8 predication bits from each edge mask bit, software may first create a 0, 1 vector by using a shr instruction with a step shift vector like 0, 1, 2, 3 (e.g. using immediate of type :v. Then each 0 or 1 of the LSB can be repeated by an and instruction to create 8 bits to the flag register. Alternatively, this can be achieved with one and instruction using a CURBE constant map of bit 0 and bit 1 mask.*
	15:8	**VertOrigin - Vertical Origin** In unit of macroblocks relative to the current picture (frame or field).
	7:0	**HorzOrigin - Horizontal Origin** In unit of macroblocks.
+2	31:16	**MotionVector[0].Vert**
	15:0	**MotionVector[0].Horz**
+3	31:0	**MotionVector[1]**
+4	31:0	**MotionVector[2]**
+5	31:0	**MotionVector[3]**
+6	31:0	**MotionVectorChroma** This field is not valid for a field motion in an interlaced frame picture where 4 MVs for chroma blocks. Notes: This field is derived from MotionVector[3:0] as described in the following section.

Indirect Data Format in VC1-IT Mode

VC1-IT mode only contains IT-COEFF indirect data which is described in Common Indirect IT-COEFF Data Structure.

Inline Data Description in MPEG2-IT Mode

The content in this command is similar to that in the MEDIA_OBJECT command in IS mode described in the Media Chapter.

Each MFD_IT_OBJECT command corresponds to the processing of one macroblock. Macroblock parameters are passed in as inline data and the non-zero DCT coefficient data for the macroblock is passed in as indirect data.

Inline data in MPEG2-IT Mode depicts the inline data format. Inline data starts at dword 7 of MFD_IT_OBJECT command. There are 7 dwords total.

	2:0	Reserved: MBZ
+1	31:16	**Reserved : MBZ**
	15:8	**VertOrigin - Vertical Origin** In unit of macroblocks relative to the current picture (frame or field).
	7:0	**HorzOrigin - Horizontal Origin** In unit of macroblocks.
+2	31:16	**Motion Vectors - Field 0, Forward, Vertical Component.** Each vector component is a 16-bit two's-complement value. The vector is relative to the current macroblock location. According to ISO/IEC 13818-2 Table 8, the valid range of each vector component is [-2048, +2047.5], implying a format of s11.1. However, it should be noted that motion vector values are sign extended to 16 bits.
	15:0	**Motion Vectors - Field 0, Forward, Horizontal Component**
+3	31:16	**Motion Vectors - Field 0, Backward, Vertical Component**
	15:0	**Motion Vectors - Field 0, Backward, Horizontal Component**
+4	31:16	**Motion Vectors - Field 1, Forward, Vertical Component**
	15:0	**Motion Vectors - Field 1, Forward, Horizontal Component**
+5	31:16	**Motion Vectors - Field 1, Backward, Vertical Component**
	15:0	**Motion Vectors - Field 1, Backward, Horizontal Component**

Indirect Data Format in MPEG2-IT Mode

MPEG2-IT mode only contains IT-COEFF indirect data which is described in Section Common Indirect IT-COEFF Data Structure.

MFX Deblocking Commands

Following are MFX Deblocking Commands:

MFX_DBK_OBJECT

MFX Error Handling

Encoder StreamOut Mode Data Structure Definition

When StreamOut is enabled, per MB (and/or per Slice, per Picture) intermediated coding data (for example, bit allocated for each MB, and so on) are sent to the memory in a fixed record format (and of fixed size) from the PAK. The per-MB records must be written in a strict raster order and with no gap (that is, every MB regardless of its mb_type and slice type, must have an entry in the StreamOut buffer). Therefore, the consumer of the StreamOut data can offset into the StreamOut Buffer (**StreamOut Data Destination Base Address**) using individual MB addresses.

Adding per macroblock stream out for PAK is for the following purposes:

- Immediate multi-pass PAK (without host or EU intervention)
  - 3200-bit conformance
  - Re-quantization
- Providing information for host for offline processing
- Providing information for updated QP's

The description for the fixed format PAK streamout record:

Streamout Pointer: Use the existing streamout pointer and enabler

Per Macroblock Information (a fixed size structure)

DWord	Bit	Description
0	31:24	**MbQpY** - Actual QPY used by the macroblock.
	23:16	**MbClock16** - MB compute clocks in 16-clock unit.
	15:8	Reserved: MBZ
	7:4	Reserved: MBZ (future conformance flags)
	3	Reserved
	2	**MbRcFlag:** MB level Rate control flag(pass through) The same value as **RateControlCounterEnable** of MFX_AVC_SLICE_STATE Command
	1	**MbInterConfFlag:** MB level InterMB conformance flag to trigger mutli-pass 1- if total Bit Count of an inter macroblock is more than Inter Conformance Max size limit in the MFX_AVC_IMG_STATE Command

DWord	Bit	Description
	0	**MbIntraConfFlag:** MB level IntraMB conformance flag to trigger mutli-pass 1- if total Bit Count of an intra macroblock is more than Intra Conformance Max size limit in the MFX_AVC_IMG_STATE Command
1	31:29	Reserved
	28:16	**MbBits:** Total Bit Count for the macroblock
	15:12	Reserved
	12:0	**MbHdrBits:** Header Bit count (bit count due to Pre-coefficient data) for the macroblock
2	31:27	Reserved
	26:0	**Cbp:** Coded Block Pattern of sub-blocks
3	31:30	Reserved
	29	**IntraMBFlag**
	28:24	**MBType5Bits**
	23:17	Reserved
	16	**ClampFlag:** Coefficient clamping flag for RC (Status) 1 - Indicates if clamping of any coefficient is done on the macroblock for Rate Control
	15:0	Reserved (future QRC stat output)

PAK Frame Statistics StreamOut

The following frame statistics are written to memory at the conclusion of a frame. If Multipass occurs, these values are overwritten by the end of any subsequent passes of the current frame (hence it contains only the final pass statistics).

The streamout is done to the MB streamout surface, starting at the next CL boundary. If MB streamout is disabled, Frame level streamout starts with 0 offset.

MFX_PAK_FRAME_STATISTICS		
Source:	**VideoCS**	
Length Bias:	**2**	
DWord	**Bit**	**Description**
0	31:16	Reserved : MBZ
	15:0	SumSliceHeader - Report the total size (in bits) of all slice headers inserted into the bitstream for this frame.
1	31:0	SumMBHeader - Report the total size (in bits) of all MB headers (non coeff bits) inserted into the bitstream for this frame.
2	31:0	SumNZC - Report the total number of nonzero coefficients after quantization.
3	31:0	Reserved: MBZ

MFX_PAK_FRAME_STATISTICS		
4	31:16	IntraMB16x16 - Count of # of MB's that were of type Intra 16x16
	15:0	IntraMB8x8 - Count of # of MB's that were of type Intra 8x8
5	31:16	IntraMB4x4 - Count of # of MB's that were of type Intra 4x4
	15:0	InterMB16x16 - Count of # of MB's that were of type Inter 16x16
6	31:16	InterMB16x8 - Count of # of MB's that were of type Inter 16x8
	15:0	InterMB8x16 - Count of # of MB's that were of type Inter 8x16
7	31:16	InterMB8x8 - Count of # of MB's that were of type Inter 8x8
	15:0	InterSkip16x16 - Count of # of MB's that were of type Inter 16x16 skip
8:49	31:0	RhoDomainStats - Each DW contains 1 of the 42 registers containing the raw Rho Domain coefficient metrics. DW 8 is QP 10 and DW 49 is QP51.
50	31:0	Reserved: MBZ

PAK Multi-Pass

Multi-Pass PAK Usages:

- Intra MB 3200-bit conformance
- Inter MB Re-quantization
- Frame level Re-quantization

How to Enable Multi-Pass PAK?

- Using the existing conditional batch buffer execution capability to skip/execute the second pass
    - How to dynamically change the condition?
        - Defined one error condition register with a mask. Do HW status page update at the end of the first pass. 0 means all OK, non-zero means there is an error condition, requiring second pass. Mask is used by the host to control what kind of multi-pass is intended.
        - For example, one error bit is 3200-bit conformance violation. Another error bit is the total bit count exceeds (too much or too little) the target range (need to define the target range in the state).
        - **The logic perfectly fits in the conditional batch buffer control logic that VCS has today in GT. There is no additional logic need to be added in VCS to support media functionality.** (**Batch Buffer Skip:** This field only takes effect if Compare Semaphore is set and the value at **Semaphore Address is NOT greater than the Semaphore Data Dword)**.
- Adding a picture level state command to enable and control the behavior of the second pass PAK
    - How to control the re-PAK? Added 3 conformance flags (error registers) in the per-MB streamout. Then the error control is based on the error register and the mask defined in

picture level states. There are 8 register flags defined out of which only the 3200-bit case has usage model defined for today. The rest are left for future usage.

Issues and Limitations:

- There is no programmable engine in MFX for flexible control: Therefore, whatever we have defined must consider flexibility

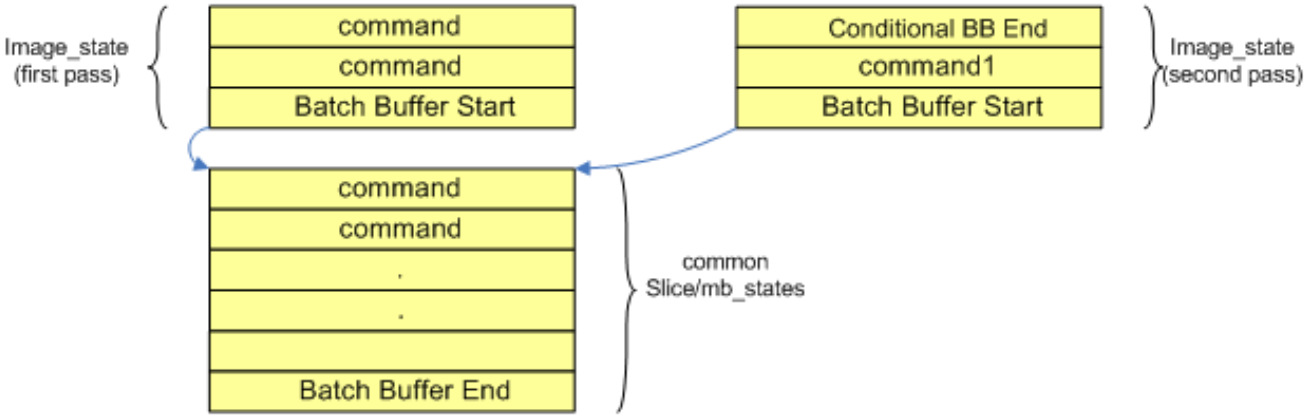
Following 2 MI packets are used inside VCS without any change to support Multipass-PAK behaviour.

- MI_Conditional_Batch_Buffer_End
- Memory Interface Registers

Driver Usage

Driver places Image states in one batch buffer and all slice level and macroblock level states into another batch buffer and link 2 batch buffers. Also replicate Image states with multipass changes in another batch buffer link them to slice/macroblock batch buffer. In this way, only Image states are replicated but not the slice/macroblock states. The image states includes all buffers defined at image(indirectMV, original pixel buffer, etc). Following changes are needed in the Multipass Image State,

- **Reset- Stream-Out Enable(disable stream out in the second pass)**
- **Set- MacroblockStatEnable (enable reading of macroblock status buffer)**
- **Reset- 3200-bit conformance (do not report 3200-bit conformance)**



Define Conditional Batch Buffer End for CS/VCSVINunit

Programming Reference

Monochrome Picture Processing

Monochrome picture is specified using the Surface State with Surface Format of 12. Therefore, MFX hardware, in either decode or encode mode, does not generate any read or write traffic for U/V components. The motivation for this bandwidth optimization is that monochrome video coding might be used for wireless display.

For Encoder:

1. No read in UV original components
2. Processing UV component - no
3. Reconstructed UV component reference picture - no
4. Filter UV component - no

For Decoder:

1. VLD mode: There is no color component coming out of the decoding pipeline in Monochrome mode and so no processing and not writing output.
2. IT mode: There is no color component in the coefficient buffer, and so no processing and not writing output.

Context Switch

There is no pre-emption for the BCS pipeline; hence every command buffer is required to contain all the states setup (preamble). Specifically, CPU cannot interrupt the BCS-BSD pipe, to stop the operation in the middle of decoding a bitstream data.

Switch of contexts can only be performed at picture boundary.

No state needs to be saved.

PMSI Support

Pipeline Flush

Implicit flush for AVC and VC1 is performed at the end of Slice : for MPEG2 is done when a new image/picture command is issued. Because MPEG2 a slice can be one MB, no point to flush. MPEG2 will snoop the next command if it is an img_state command.

Explicit flush MI (1 bit to do media pipeline vs Gx pipeline) flush and cache flush (switch reference frame) - MI flush has bit to do cache flush. MI flush is for driver synchronization.

MMIO Interface

A set of registers are defined and accessible through MMIO interface to serve multiple purposes:

- Use for system configuration
- For accessing Performance counters

The following is the table for all the MMIO addresses for MFX.

Decoder Registers

Following are Decoder Registers:

Registers
MFD_ERROR_STATUS - MFD Error Status
AVC CAVLC
AVC CABAC
VC1
MPEG2
JPEG
MFD_PICTURE_PARAM - MFD Picture Parameter
MFX_STATUS_FLAGS - MFX Pipeline Status Flags
MFX_MB_COUNT - MFX Frame Macroblock Count
MFX_SE-BIN_CT - MFX Frame BitStream SE/BIN Count

Encoder Registers

Following are the Encoder Registers:

Register
MFC_VIN_AVD_ERROR_CNTR - MFC_AVC Bitstream Decoding Front-End Parsing Logic Error Counter.
MFC_BITSTREAM_BYTECOUNT_FRAME - Reported Bitstream Output Byte Count per Frame Register
MFC_BITSTREAM_SE_BITCOUNT_FRAME - Reported Bitstream Output Bit Count for Syntax Elements Only Register
MFC_AVC_CABAC_BIN_COUNT_FRAME - Reported Bitstream Output CABAC Bin Count Register
AVC_CABAC_INSERTION_COUNT - MFC_AVC_CABAC_INSERTION_COUNT
MFC_AVC_MINSIZE_PADDING_COUNT - Bitstream Output Minimal Size Padding Count Report Register
MFC_IMAGE_STATUS_MASK - MFC Image Status Mask
MFC_IMAGE_STATUS_CONTROL - MFC Image Status Control
MFC_QUP_CT - MFC QP Status Count
MFC_BITSTREAM_BYTECOUNT_SLICE - Bitstream Output Byte Count Per Slice Report Register
MFC_BITSTREAM_SE_BITCOUNT_SLICE - Bitstream Output Bit Count for the last Syntax Element Report Register
MFX_PAK_ERROR Register
MFX_PAK_WARNING Register

Register
MFX_VP8_CNTRL_MASK - Reported BitRateControl parameter Mask
MFX_VP8_CNTRL_STATUS - Reported BitRateControl parameter Status
MFX_VP8_FRM_BYTE_CNT - Reported Final Bitstream Byte Count
MFX_VP8_FRM_ZERO_PAD - Reported Frame Zero Padding Byte Count
MFX_VP8_BRC_DQindex - Reported BitRateControl DeltaQindex
MFX_VP8_BRC_DLoopFilter - Reported BitRateControl DeltaLoopFilter
MFX_VP8_BRC_CumulativeDQindex01 - Reported BitRateControl CumulativeDeltaQindex and Qindex 01
MFX_VP8_BRC_CumulativeDQindex23 - Reported BitRateControl CumulativeDeltaQindex and Qindex 23
MFX_VP8_BRC_CumulativeDLoopFilter01 - Reported BitRateControl CumulativeDeltaLoopFilter and LoopFilter 01
MFX_VP8_BRC_CumulativeDLoopFilter23 - Reported BitRateControl CumulativeDeltaLoopFilter and LoopFilter 23
MFX_VP8_BRC_Convergence_Status - Reported BitRateControl Convergence Status

MMIO Interface

A set of registers are defined and accessible through MMIO interface to serve multiple purposes:

- Use as Status register for Bit Rate Control
- Use for Context Switch in Multipass

Register Name	Description	Register Type	Address Offset	Dec/Enc
MFX_VP8_CNTRL_MASK	BitRateControl parameter Mask register	RO	12900	Enc
MFX_VP8_CNTRL_STATUS	BitRateControl parameter Status register	RO	12904	Enc
MFX_VP8_FRM_BYTE_CNT	Final Bitstream Byte count	RO	12908	Enc
MFX_VP8_FRM_ZERO_PAD	Final Bitstream Zero Padding Byte count	RO	1290B	Enc
MFX_VP8_BRC_DQindex	BitRateControl Delta Qindex	RO	12910	Enc
MFX_VP8_BRC_DLoopFilter	BitRateControl Delta LoopFilter	RO	12914	Enc
MFX_VP8_BRC_CumulativeDQindex01	BitRateControl Cumulative Delta Qindex for Seg0/1	RW	12918	Enc
MFX_VP8_BRC_CumulativeDQindex23	BitRateControl Cumulative Delta Qindex for Seg2/3	RW	1291C	Enc
MFX_VP8_BRC_CumulativeDLoopFilter01	BitRateControl Cumulative Delta LoopFilter for Seg0/1	RW	12920	Enc
MFX_VP8_BRC_CumulativeDLoopFilter23	BitRateControl Cumulative Delta LoopFilter for Seg2/3	RW	12924	Enc
MFX_VP8_BRC_Convergence_Status	BitRateControl Convergence Status	RW	12928	Enc

The following registers are the same as above except they have a different Address Offset. They are used if the second VDbox (VP8 Encoder) exists.

Register Name	Description	Register Type	Address Offset	Dec/Enc
MFX_VP8_CNTRL_MASK	BitRateControl parameter Mask register	RO	1C900	Enc
MFX_VP8_CNTRL_STATUS	BitRateControl parameter Status register	RO	1C904	Enc
MFX_VP8_FRM_BYTE_CNT	Final Bitstream Byte count	RO	1C908	Enc
MFX_VP8_FRM_ZERO_PAD	Final Bitstream Zero Padding Byte count	RO	1C90B	Enc
MFX_VP8_BRC_DQindex	BitRateControl Delta Qindex	RO	1C910	Enc
MFX_VP8_BRC_DLoopFilter	BitRateControl Delta LoopFilter	RO	1C914	Enc
MFX_VP8_BRC_CumulativeDQindex01	BitRateControl Cumulative Delta Qindex for Seg0/1	RW	1C918	Enc
MFX_VP8_BRC_CumulativeDQindex23	BitRateControl Cumulative Delta Qindex for Seg2/3	RW	1C91C	Enc
MFX_VP8_BRC_CumulativeDLoopFilter01	BitRateControl Cumulative Delta LoopFilter for Seg0/1	RW	1C920	Enc
MFX_VP8_BRC_CumulativeDLoopFilter23	BitRateControl Cumulative Delta LoopFilter for Seg2/3	RW	1C924	Enc
MFX_VP8_BRC_Convergence_Status	BitRateControl Convergence Status	RW	1C928	Enc

Row Store Sizes and Allocations

	AVC	VC1	MPEG2	JPEG	IT	ENC	SEC ENC
vin_vmx_pixcoefind_ addr[31:6]	Bitstream	Bitstream	Bitstream	Bitstream	VDS COEF	Orig Pix	BSP data
vin_vmx_mvbsdrs_ addr[31:6]	VAD BSD		VMD RS		VDS MV	MPC MV	
vin_vmx_mpcildbmpr_ addr[31:6]	VAM MPR				VDS ILDB	MPC RS	
vin_vmx_dmv*_ addr[31:6]	VAM DMV	VCP DMV					
vin_vmx_bp_addr [31:0]		VCP BP					

	Write		Surf Size
	Read		

MPEG2 VLD Decoding Mode :

use BSD Row Store only, and

MPEG2 IT Decoding Mode :

MPEG2 IT mode does not need row-store

JPEG VLD Decoding Mode : no row store is needed

VDBOX Registers

This section describes the VDBOX Command Memory Interface registers.

MMIO Ranges

MMIO ranges for media are described in this section. The base address of MFX(x), VCS(x), VECS(x), HEVC(x) are modified.

HEVC MMIO is split into two ranges as HEVC is split into frontend and Backend. The x value can range from 0 through 7.

The address offset is defined in hierarchical manner. Each VDBOX has 16KB of MMIO address range and is allocated as shown in the table below. Unallocated address with-in 16KB space would be claimed by HEVCFE for writes and read zeros.

Offset Address of Each Engines:

UNIT	Address	Size
VCS (range 0)	0x0000 - 0x07FF	2 KB
MFX Pipe (VIN)	0x0800 - 0x0FFF	2 KB
VCS (range 1)	0x1000 - 0x1FFF	4 KB
HEVC Pipe (HWM)	0x2800 - 0x2AFF	750 B
AVP Pipe (AWM)	0x2B00 - 0x2CFF	500 B
VDENC	0x2D00-0x2DFF	1KB
Reserved	0x2E00-0x3EFF	4096B
CFCFG	0x3F00-0x3FFF	128B
SCR (no mmio space but MsgCh endpoints)		
Total allocation:		12.5 KB

VDBOX and VEBOX Offset Table:

Media Boxes	Base Address	Offset Range	Size	Media sliceid[2:0]	Media subsliceid[1:0]
VDBOX0	0x1C_0000	0x0000 - 0x3FFF	16KB	000	00
VDBOX1	0x1C_4000	0x0000 - 0x3FFF	16KB	000	01
VEBOX0	0x1C_8000	0x0000 - 0x3FFF	16KB	000	00
VDBOX2	0x1D_0000	0x0000 - 0x3FFF	16KB	001	00
VDBOX3	0x1D_4000	0x0000 - 0x3FFF	16KB	001	01
VEBOX1	0x1D_8000	0x0000 - 0x3FFF	16KB	001	00
VDBOX4	0x1E_0000	0x0000 - 0x3FFF	16KB	010	00
VDBOX5	0x1E_4000	0x0000 - 0x3FFF	16KB	010	01
VEBOX2	0x1E_8000	0x0000 - 0x3FFF	16KB	010	00
VDBOX6	0x1F_0000	0x0000 - 0x3FFF	16KB	011	00
VDBOX7	0x1F_4000	0x0000 - 0x3FFF	16KB	011	01
VEBOX3	0x1F_8000	0x0000 - 0x3FFF	16KB	011	00

Media VEBOX

This chapter describes the VEBOX Media Engine.

Media VEBOX Introduction

The VEBOX is an independent pipe with a variety of image enhancement functions.

The following sections are contained in Media VEBOX:

Feature
Denoise
Deinterlacer
Image Enhancement/Color Processing (IECP)
Capture Pipe
VEBOX State
VEBOX Surface State
VEB DI IECP Commands
Command Stream Backend - Video
Video Enhancement Engine Functions

The IECP consists of these functions:

Feature
STD - Skin Tone Detection detects colors which might represent skin.
STE - Skin Tone Enhancement modifies colors marked by STD.
GCC - Gamut Compression
ACE - Automatic Contrast Enhancement changes luma values to enhance contrast.
TCC - Total Color Control allows UV values to be modified to adjust color saturation.
ProcAmp - implements the ProcAmp DDI functions to modify the brightness, contrast, hue, and saturation.
CSC - Color Space Conversion
GEE - Gamut Expansion and Color Correction in Linear RGB Space

Programming Note
The input and output dimensions are restricted to 16K for VEBOX DN/DI/IECP/Capture Pipe.

VEBOX State and Primitive Commands

Every engine can have internal state that can be common and reused across the data entities it processes instead of reloading for every data entity.

There are two kinds of state information:

1. Surface state or state of the input and output data containers.
2. Engine state or the architectural state of the processing unit.

For example, in the case of DN/DI, architectural state information such as denoise filter strength can be the same across frames. This section gives the details of both the surface state and engine state.

Each frame should have these commands, in this order:

1. VEBOX_State
2. VEBOX_Surface_state for input & output
3. VEB_DI_IECP

Alternatively, VEBOX_Tiling_Convert can be used instead of VEB_DI_IECP.

VEBOX State

This chapter discusses various commands that control the internal functions of the VEBOX. The following commands are covered:

Command
DN/DI State Table Contents
VEBOX_IECP_STATE
VEBOX_FORWARD_GAMMA_CORRECTION_STATE
VEBOX_STATE
VEBOX_Ch_Dir_Filter_Coefficient

DN-DI State Table Contents

This section contains tables that describe the state commands that are used by the Denoise and Deinterlacer functions.

VEBOX_DNDI_STATE

VEBOX_IECP_STATE

For all piecewise linear functions in the following table, the control points must be monotonically increasing (increasing continuously) from the lowest control point to the highest. Functions which have bias/correction values associated with each control point have the additional restriction that any control points which have the same value must also have the same bias/correction value. The piecewise linear functions include:

- For Skin Tone Detection:
    - Y_point_4 to Y_point_0
    - P3L to P0L
    - P3U to P0U
    - SATP3 to SATP1
    - HUEP3 to HUEP1
    - SATP3_DARK to SATP1_DARK
    - HUEP3_DARK to HUEP1_DARK
- For ACE:
    - Ymax, Y10 to Y1 and Ymin
    - There is no state variable to set the bias for Ymin and Ymax. The biases for these two points are equal to the control point values: B0 = Ymin and B11 = Ymax. That means that if control points adjacent to Ymin and Ymax have the same value as Ymin/Ymax then the biases must also be equal to the Ymin/Ymax control points based on the restriction mentioned above.
- Forward Gamma correction
    - Gamma correction table (1K points & correction values)
- Gamut Expansion:
    - Gamma Correction (256 points & correction values)

Inverse Gamma Correction (256 points & correction values)

Command
VEBOX_STD_STE_STATE
VEBOX_ACE_LACE_STATE
VEBOX_TCC_STATE
VEBOX_PROCAMP_STATE
VEBOX_CSC_STATE
VEBOX_ALPHA_AOI_STATE
VEBOX_CCM_STATE
VEBOX_FRONT_END_CSC_STATE
VEBOX_GAMUT_CONTROL_STATE
Gamut_Expansion_Gamma_Correction
VEBOX_VERTEX_TABLE
VEBOX_CAPTURE_PIPE_STATE
VEBOX_FORWARD_GAMMA_CORRECTION_STATE
VEBOX_RGB_TO_GAMMA_CORRECTION

Surface Formats - Feature Notes

Feature
Surfaces are 4 kb aligned, chroma X offset is cache line aligned (16 byte).
If Y8/Y16 is used as the input format, it must also be used for the output format (chroma is not created by VEBOX).
If IECP and either DN or DI are enabled at the same time, it is possible to select any input that is legal for DN/DI and any output which is legal for IECP. The only exception is that if DN or DI are enabled, the IECP is not able to output P216 and P016.
16-bit data from IECP or DN is rounded when converting to 8-bit output formats.
High Speed Bypass has the same format limitations as IECP Input/Output, but the surface formats for the input and output must be the same.
Capture Input is only linear Bayer Surface Format.
Input formats for Demosaic, White Balance, Vignette and Black Level Correction must be linear Bayer.
For capture pipe, we **can** support the combination of DN and P216 and P016. For capture pipe with a P016 output the U/V output is not an average of the 4 component pixels, but the U/V for pixel 4 (the lower right pixel of the 4).
Output format Y410 is supported for DN, DI and DM modes only with IECP enabled. In non IECP cases, default of "0xFFFF" is sent if output format requires alpha.
For DN 444 input formats interlaced input content is not supported
If IECP and either DN or DI are enabled at the same time, it is possible to select any input that is legal for DN/DI and any output which is legal for IECP.

SFC

This chapter describes the SFC Media Engine.

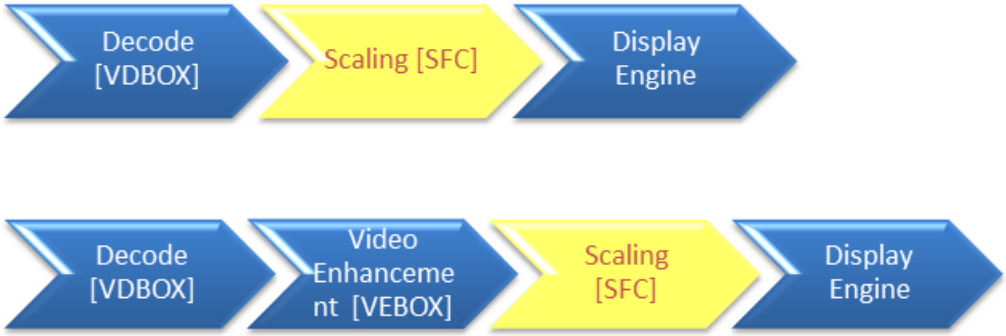
SFC Overview

Scaler & Format Converter (SFC) pipeline is a multi-format scaling engine to accelerate several media usages and achieve ultra low-power video playback.

Ultra Low-Power Usages

Several power saving techniques are brought into consideration and incorporated into the architecture of SFC pipeline: offloading from EU to fixed function to reduce Cdyn power, memory traffic reduction to lower IO and DDR power, and native surface support between acceleration engines.

Two ultra low-power playback modes are introduced to achieve sub 1-Watt solution: Decode->Scale-> Display (sprite) and Decode-> Image Enhancement-> Scale-> Display (sprite).



- In these two usages, SFC is fed by the decoder (VDBOX) and image enhancer (VEBOX) directly instead of writing to memory and read back from memory. A direct data bus is added between VD-to-SFC and VE-to-SFC. SFC will also include an internal store buffer to capture overlap pixel data between column/rows. In another word, the only IO traffic to DDR is the final scaled surface writes. All input and intermediate traffics related to SFC engine are confined inside GT and not expose to external components.
- EU-less usage: SFC is a fixed function engine architects to run concurrently along VDBOX or VEBOX. i.e. Decode and scaling will be happening at the same time, or Image enhancement and scaling will be occurring at the same time. It saves power by offloading the scaling workload off the media render engine to this dedicated engine which is much smaller.
- In both cases, scaling operation is the last processing step before final pixels are presented by the display engine. SFC is designed to generate output format native to display engine. This reduces the memory traffic caused by elimination of the extra memory copy used to convert the format incompatibility between engines. In addition, SFC supports 90 degree clockwise rotation of the final pixel surface for tablet space.

- SFC pipeline is chained together with VDBOX and VEBOX with direct interface and ability to run concurrently. VDBOX/VEBOX sends control parameters and pixel data directly to SFC through direct interface. This help reduces the IO and package power by eliminating the traffic to memory, and allows VD/VE to run concurrently along with SFC pipeline. SFC pipeline is a shared resource that can be called and accessed by VDBOX or VEBOX. A lock must be placed and granted with an acknowledgement ahead of transferring data to SFC. On completion, the lock must be removed to free up the shared resource (SFC).

SFC Commands Definition

This section contains definitions for commands used with the scaler and format converter (SFC). These commands are sent from the VDBOX/VEBOX to the SFC pipeline.

Terminology

Term	Description
DP	DisplayPort
SST, DP SST	DisplayPort Single Stream Transport
MST, DP MST	DisplayPort Multi Stream Transport

Register Access Field	Description	Implementation
R/W (Read/Write)	The value written into this register will control hardware and is the same value that will be read.	Write data is stored. Read is from the stored data. Stored value is used to control hardware.
Reserved	Unused register bit. Don't assume a value for these bits. Writes have no effect.	Write data is ignored. Read is zero.
MBZ (Must Be Zero)	Always write a zero to this register.	May be implemented as Reserved or as R/W.
PBC (Preserve Bit Contents)	Software must write the original value back to this bit. This allows new features to be added using these bits.	May be implemented as Reserved or as R/W.
Read Only	The read value is determined by hardware. Writes to this bit have no effect.	Write data is ignored. Read is from a status signal or some other internal source.
Write Only	The value written into this register will control hardware. Reads return zero.	Write data is stored. Read is zero. Stored value is used to control hardware.
R/W Clear (Read/Write Clear)	Sticky status bit. Hardware will set the bit, software can clear it with a write of 1b.	Internal hardware events set a sticky bit. Read is from the sticky bit. A write of 1b clears the sticky bit.
R/W Set (Read/Write Set)	Sticky status bit. Software can set the bit with a write of 1b. Hardware will clear the bit.	A write of 1b sets a sticky bit. Internal hardware events clear a sticky bit. Read is from the sticky bit.
Double Buffered	Write when desired and the written value will take effect at the time of the update point specified in the 'Double Buffer Update Point'	Two stages of registers used. Write data is stored into first

Register Access Field	Description	Implementation
	parameter. Reads will return the written value, which is not necessarily the value being currently used to control hardware. Some double-buffered registers have a corresponding "LIVE" read only register that provides the value being use to control hardware. Some have a specific arming sequence where a write to another register, specified in the 'Double Buffer Armed By' parameter, is required before the update can take place. Once the armed by register is written to, the written values of all registers controlled by that arming will take effect at the time of the double buffer update point. This is used to ensure atomic updates of several registers. Note: Once armed, by write to the armed by register, the registers controlled by this arming should not be changed until the double buffer update point is reached. If changed, this will disarm the sequence and will require another write to the armed by register to get it to the armed status again.	stage. Read is from the first stage stored data. First stage stored value is transferred to second stage storage at the double buffer update point. Second stage stored value is used to control hardware. Arm/disarm logic may be used for some registers to control the double buffer update point.
Write/Read Status	The value written into this register will control hardware. The read value is determined by hardware.	Write data is stored. Stored value is used to control hardware. Read is from a status signal or some other internal source.

VGA and Extended VGA Registers

This section describes the registers and the functional operation notations for the observable registers in the VGA section. This functionality is provided as a means for support of legacy applications and operating systems.

It is important to note that these registers in general have the desired effects only when running VGA display modes. The main exceptions to this are the palette interface which allows real mode DOS applications and full screen VGA applications under an OS control running in high resolution (non-VGA) modes to access the palette through the VGA register mechanisms and the use of the ST01 status bits that determine when the VGA enters display enable and sync periods. Other exceptions include the register bits that control the memory accesses through the A000:0000 and B000:0000 memory segments which are used during operating system emulation of VGA for "DOS box" applications.

Some of the functions of the VGA are enabled or defeated through the programming of the VGA control register bits that are located in the MMIO register space.

Given the legacy nature of this function, it has been adapted to the changing environment that it must operate within. The three most notable changes are the addition of high resolution display mode support, new operating system support, and the use of fixed resolution display devices (such as LCD panels). Additional control bits in the PCI Config space will affect the ability to access the registers and memory aperture associated with VGA.

Mode of Operation	VGA Disable	VGA Display	VGA Registers	Palette (VGA)	VGA Memory	VGA Banking
VGA DOS	No	Yes	Yes	Yes	Yes	No
HiRes DOS	Yes	No	Yes	Yes	No	Yes
Fullscreen DOS	Yes/No	No/Yes	Yes	Yes	Yes	Yes
DOS Emulation	Yes	No	Yes	Yes	Yes	Yes

VGA Display Mode	Dot Clock Select	Dot Clock Range	132 Column Text Support	9-Dot Disable Support	Main Use
Native	VGA Clock Select	25/28 MHz	No	No	Analog CRT (VGA connector)
Centered	Fixed at display Requirements	Product Specific	No	Yes	Digital Display
Upper Left Corner	Fixed at display Requirements	Product Specific	No	Yes	Internal Panel

Native, Centered, and Upper Left Corner support varies from product to product.

Even in the native VGA display operational modes, not all combinations of bit settings result in functional operating modes. VGA display modes have the restriction that they can be used only when all other display planes are disabled.

These registers are accessed via I/O space. The I/O space resides in the PCI compatibility hole and uses only the addresses that were part of the original VGA I/O space (which includes EGA and MDA emulation). Accesses to the VGA I/O addresses are steered to the proper bus and rely on proper setup of bridge registers. Extended VGA registers such as GR10 and GR11 use additional indexes for the already defined I/O addresses. VGA register accesses are allowed as 8 or 16 bit naturally aligned transactions only. Word transactions must have the least significant bit of the address set to zero. DWORD I/O operations should not be performed on these registers.

Some products may support access to these registers through MMIO. The access method varies and is documented elsewhere.

General Control and Status Registers

The setup, enable, and general registers are all directly accessible by the CPU. A sub indexing scheme is not used to read from and write to these registers.

Various bits in these registers provide control over the real-time status of the horizontal sync signal, the horizontal retrace interval, the vertical sync signal, and the vertical retrace interval. The horizontal retrace interval is the period during the drawing of each scan line containing active video data, when the active video data is not being displayed. This period includes the horizontal front and back porches, and the horizontal sync pulse. The horizontal retrace interval is always longer than the horizontal sync pulse. The vertical retrace interval is the period during which the scan lines not containing active video data are drawn. This includes the vertical front porch, back porch, and the vertical sync pulse. The vertical retrace interval is normally longer than the vertical sync pulse.

ST00 - Input Status 0

Address: 3C2h

Default: 00h

Attributes: Read Only

Bit	Descriptions
7	**CRT Interrupt Pending.** This bit is here for EGA compatibility and **will always return zero**. The generation of interrupts was originally enabled, through bits [4,5] of the Vertical Retrace End Register (CR11). This ability to generate interrupts at the start of the vertical retrace interval is a feature that is typically unused by DOS software and therefore is only supported through other means for use under a operating system support. 0 = CRT (vertical retrace interval) interrupt is not pending. 1 = CRT (vertical retrace interval) interrupt is pending
6:5	**Reserved.** Read as 0s.
4	**RGB Comparator / Sense.** This bit is here for compatibility and **will always return one**. Monitor detection must be done be done through the programming of hotplug registers in the MMIO space. 0 = Below threshold 1 = Above threshold
3:0	**Reserved.** Read as 0s.

ST01 - Input Status 1

Address: 3BAh/3DAh

Default: 00h

Attributes: Read Only

The address selection is dependent on CGA or MDA emulation mode as selected via the MSR register.

Bit	Descriptions
7	**Reserved (as per VGA specification).** Read as 0s.
6	**Reserved.** Read as 0.
5:4	**Video Feedback 1, 0.** These bits are connected to 2 of the 8 color bits sent to the palette. Bits 4 and 5 of the Color Plane Enable Register (AR12) selects which two of the 8 possible color bits become connected to these 2 bits of this register. These bits exist for EGA compatibility.
3	**Vertical Retrace/Video.** 0 = VSYNC inactive (Indicates that a vertical retrace interval is not taking place). 1 = VSYNC active (Indicates that a vertical retrace interval is taking place). VGA pixel generation is not locked to the display output but is loosely coupled. A VSYNC indication may not occur during the actual VSYNC going to the display but during the VSYNC that is generated as part of the VGA pixel generation. The exact relationship will vary with the VGA display operational mode. This status bit will remain active when the VGA is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now incorrectly) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. Bits 4 and 5 of the Vertical Retrace End Register (CR11) previously could program this bit to generate an interrupt at the start of the vertical retrace interval. This ability to generate interrupts at the start of the vertical retrace interval is a feature that is largely unused by legacy software. Interrupts are not supported through the VGA register bits.
2:1	**Reserved.** Read as 0s.
0	**Display Enable Output.** Display Enable is a status bit (bit 0) in VGA Input Status Register 1 that indicates when either a horizontal retrace interval or a vertical retrace interval is taking place. This bit was used with the EGA graphics system (and the ones that preceded it, including MDA and CGA). In those cases, it was important to check the status of this bit to ensure that one or the other retrace intervals was taking place before reading from or writing to the frame buffer. In these earlier systems, reading from or writing to the frame buffer at times outside the retrace intervals meant that the CRT controller would be denied access to the frame buffer. Those behaviors resulted in either "snow" or a flickering display. This bit provides compatibility with software designed for those early graphics controllers. This bit is currently used in DOS applications that access the palette to prevent the sparkle associated with read and write accesses to the palette RAM with the same address on the same clock cycle. **This status bit remains active when the VGA display is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now considered incorrect) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. When in panel fitting VGA or centered VGA operation, the meaning of these bits will not be consistent with native VGA timings.** 0 = Active display data is being sent to the display. Neither a horizontal retrace interval or a vertical retrace interval is currently taking place. 1 = Either a horizontal retrace interval (horizontal blanking) or a vertical retrace interval (vertical blanking) is

Bit	Descriptions
	currently taking place.

FCR - Feature Control

Address: 3BAh/3DAh - Write; 3CAh - Read

Default: 00h

Attributes: Read/Write

The address used for writes is dependent on CGA or MDA emulation mode as selected via the MSR register. In the original EGA, bits 0 and 1 were used as part of the feature connector interface. Feature connector is not supported in these devices and those bits will always read as zero.

Bit	Descriptions
7:4	**Reserved.** Read as 0.
3	**VSYNC Control.** This bit is provided for compatibility only and has no other function. Reads and writes to this bit have no effect other than to change the value of this bit. The previous definition of this bit selected the output on the VSYNC pin. 0 = Was used to set VSYNC output on the VSYNC pin (default). 1 = Was used to set the logical 'OR' of VSYNC and Display Enable output on the VSYNC pin. This capability was not typically very useful.
2:0	**Reserved.** Read as 0.

MSR - Miscellaneous Output

Address: 3C2h - Write; 3CCh - Read

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7	**CRT VSYNC Polarity.** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. Sync polarity was used in VGA to signal the monitor how many lines of active display are being generated. 0 = Positive Polarity (default). 1 = Negative Polarity.
6	**CRT HSYNC Polarity.** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with

Bit	Descriptions
	the original VGA when used in the VGA native mode. 0 = Positive Polarity (default). 1 = Negative Polarity
5	**Page Select.** In Odd/Even Memory Map Mode 1 (GR6), this bit selects the upper or lower 64 KB page in display memory for CPU access: 0 = Upper page (default) 1 = Lower page. Selects between two 64KB pages of frame buffer memory during standard VGA odd/even modes (modes 0h through 5h). Bit 1 of register GR06 can also program this bit in other modes. This bit is would normally set to 1 by the software.
4	**Reserved.** Read as 0.
3:2	**Clock Select.** These bits can select the dot clock source for the CRT interface. The bits should be used to select the dot clock in standard native VGA modes only. When in the centering or upper left corner modes, these bits should be set to have no effect on the clock rate. The actual frequencies that these bits select, if they have any affect at all, is programmable through the PLL MMIO registers. 00 = CLK0, 25.175 MHz (for standard VGA modes with 640 pixel (8-dot) horizontal resolution) (default) 01 = CLK1, 28.322 MHz. (for standard VGA modes with 720 pixel (9-dot) horizontal resolution) 10 = Was used to select an external clock (now unused) 11 = Reserved
1	**A0000-BFFFFh Memory Access Enable.** VGA Compatibility bit enables access to video memory (frame buffer) at A0000-BFFFFh. When disabled, accesses to VGA memory are blocked in this region. This bit is independent of and does not block CPU access to the video linear frame buffer at other addresses. 0 = Prevent CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture (default). 1 = Allow CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture. This memory must be mapped as UC by the CPU.
0	**I/O Address Select.** This bit selects 3Bxh or 3Dxh as the I/O address for the CRT Controller registers, the Feature Control Register (FCR), and Input Status Register 1 (ST01). Presently ignored (whole range is claimed), but will "ignore" 3Bx for color configuration or 3Dx for monochrome. It is typical in AGP chipsets to shadow this bit and properly steer I/O cycles to the proper bus for operation where a MDA exists on another bus such as ISA. 0 = Select 3Bxh I/O address (MDA emulation) (default). 1 = Select 3Dxh I/O address (CGA emulation).

In standard VGA modes using the analog VGA connector, bits 7 and 6 indicate which of the three standard VGA vertical resolutions the standard VGA display should use. Extended modes, including those with a vertical resolution of 480 scan lines, may use a setting of 0 for both of these bits. Different

connector standards and timing standards specify the proper use of sync polarity. This setting was "reserved" in the VGA standard.

Analog CRT Display Sync Polarities

V	H	Display	Horizontal Frequency	Vertical Frequency
P	P	200 Line	15.7 KHz	60 Hz
N	P	350 Line	21.8 KHz	60 Hz
P	N	400 Line	31.5 KHz	70 Hz
N	N	480 Line	31.5 KHz	60 Hz

Sequencer Registers

To access registers the VGA Sequencer Index register (SRX) at address 3C4h is written with the index of the desired register. Then the desired register is accessed through the data port for the sequencer registers at address 3C5.

SRX - Sequencer Index

Address: 3C4h

Default: 00h

Attributes: Read/Write

Bit	Description
7:3	**Reserved.** Read as 0s.
2:0	**Sequencer Index.** This field contains a 3-bit Sequencer Index value used to access sequencer data registers at indices 0 through 7.

SR00 - Sequencer Reset

Address: 3C5h(Index=00h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:2	**Reserved.** Read as 0.
1	**Reserved.** Reserved for VGA compatibility (was reset).
0	**Reserved.** Reserved for VGA compatibility. (was reset)

SR01 - Clocking Mode

Address: 3C5h (Index=01h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:6	**Reserved.** Read as 0s.
5	**Screen Off.** 0 = Normal Operation (default). 1 = Disables video output (blanks the screen) and turns off display data fetches. Synchronization pulses to the display, however, are maintained. Setting this bit to 1 had been used as a way to more rapidly update and improve CPU access performance to the frame buffer during VGA modes. In non-VGA modes (VGA Disable=1), this bit has no effect. Before the VGA is disabled through the MMIO VGA control register, this bit should be set to stop the memory accesses from the display. The following sequence must be used when disabling the VGA plane. 1. Write SR01 to set bit 5 = 1 to disable video output. 2. Wait for 100us. 3. Disable the VGA plane via Bit 31 of the MMIO VGA control register (location found in the MMIO display register programming specification).
4	**Shift 4.** 0 = Load video shift registers every 1 or 2 character clocks (depending on bit 2 of this register) (default). 1 = Load shift registers every 4th character clock.
3	**Dot Clock Divide.** Setting this bit to 1 stretches doubles all horizontal timing periods that are specified in the VGA horizontal CRTC registers. This bit is used in standard VGA 40-column text modes to stretch timings to create horizontal resolutions of either 320 or 360 pixels (as opposed to 640 or 720 pixels, normally used in standard VGA 80-column text modes). The effect of this is that there will actually be twice the number of pixels sent to the display per line. 0 = Pixel clock is left unaltered (used for 640 (720) pixel modes); (default). 1 = Pixel clock divided by 2 (used for 320 (360) pixel modes).
2	**Shift Load.** Bit 4 of this register must be 0 for this bit to be effective. 0 = Load video data shift registers every character clock (default). 1 = Load video data shift registers every other character clock.
1	**Reserved.** Read as 0.
0	**8/9 Dot Clocks.** This bit determines whether a character clock is 8 or 9 dot clocks long if clock doubling is disabled and 16 or 18 clocks if it is. This also changes the interpretation of the pixel panning values (see chart). An additional control bit determines if this bit is to be ignored and 8-dot characters are to be used always. The 9-dot disable would be used when doubling the horizontal pixels on a 1280 wide display or non-doubling on a 640 wide display. Panning however will occur according to the expected outcome. 0 = 9 dot clocks (9 horizontal pixels) per character in text modes with a horizontal resolution of 720 pixels. 1 = 8 dot clocks (8 horizontal pixels) per character in text or graphics modes with a horizontal resolution of

Bit	Descriptions
	640 pixels.

SR02 - Plane/Map Mask

Address: 3C5h (Index=02h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:4	**Reserved.** Read as 0s.
3:0	**Memory Planes [3:0] Processor Write Access Enable.** In both the Odd/Even Mode and the Chain 4 Mode, these bits still control access to the corresponding color plane. 0 = Disable. 1 = Enable. This register is referred to in the VGA standard as the Map Mask Register.

SR03 - Character Font

Address: 3C5h (index=03h)

Default: 00h

Attributes: Read/Write

In text modes, bit 3 of the video data's attribute byte normally controls the foreground intensity. This bit may be redefined to control switching between character sets. This latter function is enabled whenever there is a difference in the values of the Character Font Select A and the Character Font Select B bits. If the two values are the same, the character select function is disabled and attribute bit 3 controls the foreground intensity.

Bit 1 of the Memory Mode Register (SR04) must be set to 1 for the character font select function of this register to be active. Otherwise, only character maps 0 and 4 are available.

Bit	Descriptions
7:6	**Reserved.** Read as 0s.
3:2,5	**Character Map Select Bits for Character Map B.** These three bits are used to select the character map (character generator tables) to be used as the secondary character set (font). The numbering of the maps is not sequential.

Bit [3:2,5]	Map Number	Table Location
00,0	0	1st 8KB of plane 2 at offset 0 (default)
00,1	4	2nd 8KB of plane 2 at offset 8K
01,0	1	3rd 8KB of plane 2 at offset 16K
01,1	5	4th 8KB of plane 2 at offset 24K
10,0	2	5th 8KB of plane 2 at offset 32K

Bit	Descriptions
	10,1 | 6 | 6th 8KB of plane 2 at offset 40K 11,0 | 3 | 7th 8KB of plane 2 at offset 48K 11,1 | 7 | 8th 8KB of plane 2 at offset 56K
1:0,4	**Character Map Select Bits for Character Map A.** These three bits are used to select the character map (character generator tables) to be used as the primary character set (font). The numbering of the maps is not sequential. Bit [1:0,4] | Map Number | Table Location 00,0 | 0 | 1st 8KB of plane 2 at offset 0 (default) 00,1 | 4 | 2nd 8KB of plane 2 at offset 8K 01,0 | 1 | 3rd 8KB of plane 2 at offset 16K 01,1 | 5 | 4th 8KB of plane 2 at offset 24K 10,0 | 2 | 5th 8KB of plane 2 at offset 32K 10,1 | 6 | 6th 8KB of plane 2 at offset 40K 11,0 | 3 | 7th 8KB of plane 2 at offset 48K 11,1 | 7 | 8th 8KB of plane 2 at offset 56K

SR04 - Memory Mode Register

Address: 3C5h (index=04h)

Default: 00h

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3	**Chain 4 Mode.** The selections made by this bit affect both CPU Read and write accesses to the frame buffer. 0 = The manner in which the frame buffer memory is mapped is determined by the setting of bit 2 of this register (default). 1 = The frame buffer memory is mapped in such a way that the function of address bits 0 and 1 are altered so that they select planes 0 through 3. This setting is used in mode x13 to allow all four planes to be accessed via sequential addresses.
2	**Odd/Even Mode.** Bit 3 of this register must be set to 0 for this bit to be effective. The selections made by this bit affect only non-paged CPU accesses to the frame buffer through the VGA aperture. 0 = The frame buffer memory is mapped in such a way that the function of address bit 0 such that even addresses select planes 0 and 2 and odd addresses select planes 1 and 3 (default). 1 = Addresses sequentially access data within a bit map, and the choice of which map is accessed is made according to the value of the Plane Mask Register (SR02).
1	**Extended Memory Enable.** This bit must be set to 1 to enable the selection and use of character maps in plane 2 via the Character Map Select Register (SR03). 0 = Disable CPU accesses to more than the first 64KB of VGA standard memory (default). 1 = Enable CPU accesses to the rest of the 256KB total VGA memory beyond the first 64KB.

Bit	Description
0	**Reserved.** Read as 0.

SR07 - Horizontal Character Counter Reset

Address: 3C5h (index=07h)

Default: 00h

Attributes: Read/Write

For standard VGAs, writing this register (with any data) causes the horizontal character counter to be held in reset (the character counter output will remain 0). It remained in reset until a write occurred to any other sequencer register location with SRX set to an index of 0 through 6. In this implementation that sequence has no such special effect.

The vertical line counter is clocked by a signal derived from the horizontal display enable (which does not occur if the horizontal counter is held in reset). Therefore, if a write occurs to this register during the vertical retrace interval, both the horizontal and vertical counters will be set to 0. A write to any other sequencer register location (with SRX set to an index of 0 through 6) may then be used to start both counters with reasonable synchronization to an external event via software control. Although this was a standard VGA register, it was not documented.

Bit	Description
7:0	**Horizontal Character Counter.**

Graphics Controller Registers

Accesses to the registers of the VGA Graphics Controller are done through the use of address 3CEh written with the index of the desired register. Then the desired register is accessed through the data port for the graphics controller registers at address 3CFh. Indexes 10 and 11 must only be accessed through the I/O space.

GRX - GRX Graphics Controller Index Register

Address: 3CEh

Default:
000UUUUUb (U=Undefined)
Attributes:
Read/Write

Bit	Description
7:5	**Reserved.** Read as 0.
4:0	**Graphics Controller Register Index.** This field selects any one of the graphics controller registers (GR00-GR18) to be accessed via the data port at address 3CFh.

GR00 - Set/Reset Register

Address: 3CFh (index=00h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Set/Reset Plane [3:0].** When the Write Mode bits (bits 0 and 1) of the Graphics Mode Register (GR05) are set to select Write Mode 0, all 8 bits of each byte of each memory plane are set to either 1 or 0 as specified in the corresponding bit in this register, if the corresponding bit in the Enable Set/Reset Register (GR01) is set to 1. When the Write Mode bits (bits 0 and 1) of the Graphics Mode Register (GR05) are set to select Write Mode 3, all CPU data written to the frame buffer is rotated, then logically ANDed with the contents of the Bit Mask Register (GR08), and then treated as the addressed data's bit mask, while value of these four bits of this register are treated as the color value.

GR01 - Enable Set/Reset Register

Address: 3CFh (Index=01h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Enable Set/Reset Plane [3:0].** This register works in conjunction with the Set/Reset Register (GR00). The Write Mode bits (bits 0 and 1) must be set for Write Mode 0 for this register to have any effect. 0 = The corresponding memory plane can be read from or written to by the CPU without any special bitwise operations taking place. 1 = The corresponding memory plane is set to 0 or 1 as specified in the Set/Reset Register (GR00).

GR02 - Color Compare Register

Address: 3CFh (Index=02h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Color Compare Plane [3:0].** When the Read Mode bit (bit 3) of the Graphics Mode Register (GR05) is set to select Read Mode 1, all 8 bits of each byte of each of the 4 memory planes of the frame buffer corresponding to the address from which a CPU read access is being performed are compared to the corresponding bits in this register (if the corresponding bit in the Color Don't Care Register (GR07) is set to 1). The value that the CPU receives from the read access is an 8-bit value that shows the result of this comparison, wherein value of 1 in a given bit position indicates that all of the corresponding bits in the bytes across all of the memory planes that were included in the comparison had the same value as their memory plane's respective bits in this register.

GR03 - Data Rotate Register

Address: 3CFh (Index=03h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:5	**Reserved.** Read as 0.
4:3	**Function Select.** These bits specify the logical function (if any) to be performed on data that is meant to be written to the frame buffer (using the contents of the memory read latch) just before it is actually stored in the frame buffer at the intended address location. 00 = Data being written to the frame buffer remains unchanged, and is simply stored in the frame buffer. 01 = Data being written to the frame buffer is logically ANDed with the data in the memory read latch before it is actually stored in the frame buffer. 10 = Data being written to the frame buffer is logically ORed with the data in the memory read latch before it is actually stored in the frame buffer. 11 = Data being written to the frame buffer is logically XORed with the data in the

Bit	Description
	memory read latch before it is actually stored in the frame buffer.
2:0	**Rotate Count.** These bits specify the number of bits to the right to rotate any data that is meant to be written to the frame buffer just before it is actually stored in the frame buffer at the intended address location.

GR04 - Read Plane Select Register

Address: 3CFh (Index=04h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:2	**Reserved.** Read as 0.
1:0	**Read Plane Select.** These two bits select the memory plane from which the CPU reads data in Read Mode 0. In Odd/Even Mode, bit 0 of this register is ignored. In Chain 4 Mode, both bits 1 and 0 of this register are ignored. The four memory planes are selected as follows: 00 = Plane 0 01 = Plane 1 10 = Plane 2 11 = Plane 3 These two bits also select which of the four memory read latches may be read via the Memory read Latch Data Register (CR22). The choice of memory read latch corresponds to the choice of plane specified in the table above. The Memory Read Latch Data register and this additional function served by 2 bits are features of the VGA standard that were never documented.

GR05 - Graphics Mode Register

Address: 3CFh (Index=05h)

Default: 0UUU U0UUb (U=Undefined)

Attributes:
Read/Write

Bit	Description
7	**Reserved.** Read as 0.

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>6:5</td><td>
Shift Register Control. In standard VGA modes, pixel data is transferred from the 4 graphics memory planes to the palette via a set of 4 serial output bits. These 2 bits of this register control the format in which data in the 4 memory planes is serialized for these transfers to the palette.

Bits [6:5]=00

One bit of data at a time from parallel bytes in each of the 4 memory planes is transferred to the palette via the 4 serial output bits, with 1 of each of the serial output bits corresponding to a memory plane. This provides a 4-bit value on each transfer for 1 pixel, making possible a choice of 1 of 16 colors per pixel.

Serial

</table>

Bits [6:5]=01

Two bits of data at a time from parallel bytes in each of the 4 memory planes are transferred to the palette in a pattern that alternates per byte between memory planes 0 and 2, and memory planes 1 and 3. First the even-numbered and odd-numbered bits of a byte in memory plane 0 are transferred via serial output bits 0 and 1, respectively, while the even-numbered and odd-numbered bits of a byte in memory plane 2 are transferred via serial output bits 2 and 3. Next, the even-numbered and odd-numbered bits of a byte in memory plane 1 are transferred via serial output bits 0 and 1, respectively, while the even-numbered and odd-numbered bits of memory plane 3 are transferred via serial out bits 1 and 3. This provides a pair of 2-bit values (one 2-bit value for each of 2 pixels) on each transfer, making possible a choice of 1 of 4 colors per pixel.

Bit	Description
	Bit 2 plane2 bit6 plane2 bit4 plane2 bit2 plane2 bit0 plane3 bit6 plane3 bit4 plane3 bit2 plane3 bit0 Bit 1 plane0 bit7 plane0 bit5 plane0 bit3 plane0 bit1 plane1 bit7 plane1 bit5 plane1 bit3 plane1 bit1 Bit 0 plane0 bit6 plane0 bit4 plane0 bit2 plane0 bit0 plane1 bit6 plane1 bit4 plane1 bit2 plane1 bit0 This alternating pattern is meant to accommodate the use of the Odd/Even mode of organizing the 4 memory planes, which is used by standard VGA modes 2h and 3h. **Bits [6:5]=1x** Four bits of data at a time from parallel bytes in each of the 4 memory planes are transferred to the palette in a pattern that iterates per byte through memory planes 0 through 3. First the 4 most significant bits of a byte in memory plane 0 are transferred via the 4 serial output bits, followed by the 4 least significant bits of the same byte. Next, the same transfers occur from the parallel byte in memory planes 1, 2 and lastly, 3. Each transfer provides either the upper or lower half of an 8 bit value for the color for each pixel, making possible a choice of 1 of 256 colors per pixel. This is the setting used in mode x13. Serial Out 1st Xfer 2nd Xfer 3rd Xfer 4th Xfer 5th Xfer 6th Xfer 7th Xfer 8th Xfer Bit 3 plane0 bit7 plane0 bit3 plane1 bit7 plane1 bit3 plane2 bit7 plane2 bit3 plane3 bit7 plane3 b3it Bit 2 plane0 bit6 plane0 bit2 plane1 bit6 plane1 bit2 plane2 bit6 plane2 bit2 plane3 bit6 plane3 bit2 Bit 1 plane0 bit5 plane0 bit1 plane1 bit5 plane1 bit1 plane2 bit5 plane2 bit1 plane3 bit5 plane3 bit1 Bit 0 plane0 bit4 plane0 bit0 plane1 bit4 plane1 bit0 plane2 bit4 plane2 bit0 plane3 bit4 plane3 bit0 This pattern is meant to accommodate mode 13h, a standard VGA 256-color graphics mode.
4	**Odd/Even Mode.** 0 = Addresses sequentially access data within a bit map, and the choice of which map is accessed is made according to the value of the Plane Mask Register (SR02). 1 = The frame buffer is mapped in such a way that the function of

Bit	Description
	address bit 0 is such that even addresses select memory planes 0 and 2 and odd addresses select memory planes 1 and 3. This works in a way that is the inverse of (and is normally set to be the opposite of) bit 2 of the Memory Mode Register (SR02).
3	**Read Mode.** 0 = During a CPU read from the frame buffer, the value returned to the CPU is data from the memory plane selected by bits 1 and 0 of the Read Plane Select Register (GR04). 1 = During a CPU read from the frame buffer, all 8 bits of the byte in each of the 4 memory planes corresponding to the address from which a CPU read access is being performed are compared to the corresponding bits in this register (if the corresponding bit in the Color Don't Care Register (GR07) is set to 1). The value that the CPU receives from the read access is an 8-bit value that shows the result of this comparison. A value of 1 in a given bit position indicates that all of the corresponding bits in the bytes across all 4 of the memory planes that were included in the comparison had the same value as their memory plane's respective bits in this register.
2	**Reserved.** Read as 0.
1:0	**Write Mode.** 00 = Write Mode 0 - During a CPU write to the frame buffer, the addressed byte in each of the 4 memory planes is written with the CPU write data after it has been rotated by the number of counts specified in the Data Rotate Register

Bit	Description
	(GR03). If, however, the bit(s) in the Enable Set/Reset Register (GR01) corresponding to one or more of the memory planes is set to 1, then those memory planes will be written to with the data stored in the corresponding bits in the Set/Reset Register (GR00). 01 = Write Mode 1 - During a CPU write to the frame buffer, the addressed byte in each of the 4 memory planes is written to with the data stored in the memory read latches. (The memory read latches stores an unaltered copy of the data last read from any location in the frame buffer.) 10 = Write Mode 2 - During a CPU write to the frame buffer, the least significant 4 data bits of the CPU write data is treated as the color value for the pixels in the addressed byte in all 4 memory planes. The 8 bits of the Bit Mask Register (GR08) are used to selectively enable or disable the ability to write to the corresponding bit in each of the 4 memory planes that correspond to a given pixel. A setting of 0 in a bit in the Bit Mask Register at a given bit position causes the bits in the corresponding bit positions in the addressed byte in all 4 memory planes to be written with value of their counterparts in the memory read latches. A setting of 1 in a Bit Mask Register at a given bit position causes the bits in the corresponding bit positions in the addressed byte in all 4 memory planes to be written with the 4 bits taken from the CPU write data to thereby cause the pixel corresponding to these bits to be set to the color value. 11 = Write Mode 3 - During a CPU write to the frame buffer, the CPU write data is logically ANDed with the contents of the Bit Mask Register (GR08). The result of this ANDing is treated as the bit mask used in writing the contents of the Set/Reset Register (GR00) are written to addressed byte in all 4 memory planes.

GR06 - Miscellaneous Register

Address: 3CFh (Index=06h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description

Bit	Description
7:4	**Reserved.** Read as 0s.
3:2	**Memory Map Mode.** These 2 bits control the mapping of the VGA address range for frame buffer into the CPU address space as follows: 00 = A0000h - BFFFFh 01 = A0000h - AFFFFh 10 = B0000h - B7FFFh 11 = B8000h - BFFFFh This function is used in standard VGA modes, extended VGA modes (132 column text), and in non-VGA modes (hi-res). 132 column text modes are no longer supported. VGA aperture memory accesses are also controlled by the PCI configuration Memory Enable bit and MSR<1>. For accesses using GR10 and GR11 to paged VGA RAM or to device MMIO registers, set these bits to 01 to select the (A0000-AFFFF) range. The CPU must map this memory as uncacheable (UC).
1	**Chain Odd/Even.** This bit provides the ability to alter the interpretation of address bit A0, so that it may be used in selecting between the odd-numbered memory planes (planes 1 and 3) and the even-numbered memory planes (planes 0 and 2). 0 = A0 functions normally. 1 = A0 is switched with a high order address bit, in terms of how it is used in address decoding. The result is that A0 is used to determine which memory plane is being accessed (A0=0 for planes 0 and 2 and A0=1 for planes 1 and 3).
0	**Graphics/Text Mode.** This is one of two bits that are used to determine if the VGA is operating in text or graphics modes. The other bit is in AR10[0], these two bits need to be programmed in a consistent manner to achieve the proper results. 0 = Text mode. 1 = Graphics mode.

GR07 - Color Don't Care Register

Address: 3CFh (Index=07h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Ignore Color Plane [3:0].** These bits have effect only when bit 3 of the Graphics Mode Register (GR05) is set to 1 to select read mode 1. 0 = The corresponding bit in the Color Compare Register (GR02) will not be included in color comparisons. 1 = The corresponding bit in the Color Compare Register (GR02) is used in color comparisons.

GR08 - Bit Mask Register

Address: 3CFh (Index=08h)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Bit Mask.** 0 = The corresponding bit in each of the 4 memory planes is written to with the corresponding bit in the memory read latches. 1 = Manipulation of the corresponding bit in each of the 4 memory planes via other mechanisms is enabled. This bit mask applies to any writes to the addressed byte of any or all of the 4 memory planes, simultaneously. This bit mask is applicable to any data written into the frame buffer by the CPU, including data that is also subject to rotation, logical functions (AND, OR, XOR), and Set/Reset. To perform a proper read-modify-write cycle into frame buffer, each byte must first be read from the frame buffer by the CPU (and this will cause it to be stored in the memory read latches), this Bit Mask Register must be set, and the new data then written into the frame buffer by the CPU.

GR10 - Address Mapping

Address: 3CFh (Index=10h)

Default: 00h

Attributes:
Read/Write

This register must only be accessed using I/O operations.

Bit	Description

Bit	Description
7:4	**Page Select Extension - Unused** These bits form the upper bits of a 12-bit page selection value. When combined with the GR11 <7:0> bits they define the offset into stolen memory to the 64KB page that is accessible via the VGA Memory paging mechanism. These bits are ignored.
3	**Reserved**
2:1	**Paging Map Target.** When paging is enabled, these bits determine the target for data cycle accesses through the VGA memory aperture. VGA graphics memory starts from the base of graphics data stolen memory defined in the PCI configuration BDSM register. VGA display uses the first four 64KB pages of VGA graphics memory. 00 = VGA Graphics Memory 01 = Reserved 10 = Reserved 11 = Reserved
0	**Page Mapping Enable.** This mode allows the mapping of the VGA memory address space. Once this is enabled, no VGA memory address swizzle will be performed, addresses are directly mapped to memory. A single paging register is used to map the 64KB [A0000:AFFFF] window. An internal address is generated using GR11 as the address lines extension to the lower address lines of the access A[15:2]. When mapping is enabled, the B0000:BFFFF area must be disabled using GR06<3:2>=01. The use of addresses in the A0000-BFFFF range require that both the graphics device PCI configuration memory enable and MSR<1> be enabled. 0 = Disable (default) 1 = Enable

GR11 - Page Selector

Address: 3CFh (Index=11h)

Default: 00h

Attributes:
Read/Write

This register must only be accessed using I/O operations.

Bit	Description
7	**Reserved**
6:0	**Page Select.** When concatenated with the GR10<7:4> bits, selects a 64KB window within target area when Page Mapping is enabled (GR10[0]=1). This requires that the graphics device PCI configuration space memory enable, the GR06<3:2> bits to be 01 (select A0000-AFFFF only), and the MSR<1:1> bit to be set. This register provides the Address[22:16] bits for the access. VGA paging of frame buffer memory is for non-VGA packed modes only and should not be enabled when using basic VGA modes.

GR18 - Software Flags

Address: 3CFh (Index=18h)

Default: 00h

Attributes:
Read/Write

Bit	Description
7:0	**Software Flags.** Used as scratch pad space in video BIOS. These bits are separate from the bits which appear in the MMIO space. They are used specifically by the SMI BIOS which does not have access to MMIO at the time they are required. These register bits have no effect on H/W operation.

Attribute Controller Registers

Unlike the other sets of indexed registers, the attribute controller registers are not accessed through a scheme employing entirely separate index and data ports. Address 3C0h is used both as the read and write for the index register, and as the write address for the data port. Address 3C1h is the read address for the data port.

To write to the attribute controller registers, the index of the desired register must be written to address 3C0h, and then the data is written to the very same address. A flip-flop alternates with each write to address 3C0h to change its function from writing the index to writing the actual data, and back again. This flip-flop may be deliberately set so that address 3C0h is set to write to the index (which provides a way to set it to a known state) by performing a read operation from Input Status Register 1 (ST01) at address 3BAh or 3DAh, depending on whether the graphics system has been set to emulate an MDA or a CGA as per MSR[0].

To read from the attribute controller registers, the index of the desired register must be written to address 3C0h, and then the data is read from address 3C1h. A read operation from address 3C1h does not reset the flip-flop to writing to the index. Only a write to 3C0h or a read from 3BAh or 3DAh, as described above, will toggle the flip-flop back to writing to the index.

ARX - Attribute Controller Index Register

Address: 3C0h

Default:
00UU UUUUb (U=Undefined)
Attributes:
Read/Write

Bit	Description
7:6	**Reserved.** Read as 0s.
5	**Video Enable.** In the VGA standard, this is called the "Palette Address Source" bit. Clearing this bit will cause the VGA display data to become all 00 index values. For the default palette, this will cause a black screen. The video timing signals continue. Another control bit will turn video off and stop the data fetches. 0 = Disable. Attribute controller color registers (AR[00:0F]) can be accessed by the CPU. 1 = Enable. Attribute controller color registers (AR[00:0F]) are inaccessible by the CPU.
4:0	**Attribute Controller Register Index.** These five bits are used to select any one of the attribute controller registers (AR[00:14]), to be accessed.

AR[00:0F] - Palette Registers [0:F]

Address: Read at 3C1h and Write at 3C0h; (index=00h-0Fh)

Default: 00UU UUUUb (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5:0	**Palette Bits P[5:0].** In each of these 16 registers, these are the lower 6 of 8 bits that are used to map either text attributes or pixel color input values (for modes that use 16 colors) to the 256 possible colors available to be selected in the palette. Bits 3 and 2 of the Color Select Register (AR14) supply bits P7 and P6 for the values contained in all 16 of these registers. Bits 1 and 0 of the Color Select Register (AR14) can also replace bits P5 and P4 for the values contained in all 16 of these registers, if bit 7 of the Mode Control Register (AR10) is set to 1.

AR10 - Mode Control Register

Address: Read at 3C1h and Write at 3C0h; (index=10h)

Default: UUh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7	**Palette Bits P5, P4 Select.** **0** = P5 and P4 for each of the 16 selected colors (for modes that use 16 colors) are individually provided by bits 5 and 4 of their corresponding Palette Registers (AR[00:0F]). **1** = P5 and P4 for all 16 of the selected colors (for modes that use 16 colors) are provided by bits 1 and 0 of Color Select Register (AR14).
6	**Pixel Width/Clock Select.** **0** = Six bits of video data (translated from 4 bits via the palette) are output every dot clock. **1** = Two sets of 4 bits of data are assembled to generate 8 bits of video data which is output every other dot clock, and the Palette Registers (AR[00:0F]) are bypassed. This bit is set to 0 for all of the standard VGA modes, except mode 13h.
5	**Pixel Panning Compatibility.** **0** = Scroll both the upper and lower screen regions horizontally as specified in the Pixel Panning Register (AR13). **1** = Scroll only the upper screen region horizontally as specified in the Pixel Panning Register (AR13). This bit has application only when split-screen mode is being used, where the display area is divided into distinct upper and lower regions which function somewhat like separate displays.

Bit	Description
4	**Reserved.** Read as 0.
3	**Enable Blinking/Select Background Intensity.** **0** = Disables blinking in graphics modes, and for text modes, sets bit 7 of the character attribute bytes to control background intensity, instead of blinking. **1** = Enables blinking in graphics modes and for text modes, sets bit 7 of the character attribute bytes to control blinking, instead of background intensity. The blinking rate is derived by dividing the VSYNC signal. The Blink Rate Control field of the VGA control register defines the blinking rate.
2	**Enable Line Graphics Character Code.** **0** = Every 9th pixel of a horizontal line (i.e., the last pixel of each horizontal line of each 9-pixel wide character box) is assigned the same attributes as the background of the character of which the given pixel is a part. **1** = Every 9th pixel of a horizontal line (i.e., the last pixel of each horizontal line of each 9-pixel wide character box) is assigned the same attributes as the 8th pixel if the character of which the given pixel is a part. This setting is intended to accommodate the line-drawing characters of the PC's extended ASCII character set -- characters with an extended ASCII code in the range of B0h to DFh. In some literature describing the VGA standard, the range of extended ASCII codes that are said to include the line-drawing characters is mistakenly specified as C0h to DFh, rather than the correct range of B0h to DFh.
1	**Select Display Type.** **0** = Attribute bytes in text modes are interpreted as they would be for a color display. **1** = Attribute bytes in text modes are interpreted as they would be for a monochrome display.
0	**Graphics/Alphanumeric Mode.** This bit (along with GR06[0]) select either graphics mode or text mode. These two bits must be programmed in a consistent manner to achieve the desired results. **0** = Alphanumeric (text) mode. **1** = Graphics mode.

AR11 - Overscan Color Register

Address: Read at 3C1h and Write at 3C0h; (index=11h)

Default: UUh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:0	**Overscan.** These 8 bits select the overscan (border) color index value. The actual border color will be determined by the contents of the palette at the selected index. The border color is displayed between the end of active and the beginning of blank or the end of blank and the beginning of active on CRT type devices driven from the DAC output port. For native VGA modes on digital display ports, some devices have the option of including the border in the active region or not, depending on a control bit in the port control register. For centered VGA modes, the VGA control register determines if the border is included in the centered region or not. For monochrome displays, this value should be set to 00h.

AR12 - Memory Plane Enable Register

Address: Read at 3C1h and Write at 3C0h; (index=12h)

Default: 00UU UUUUb (U=Undefined)

Attributes:
Read/Write

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>7:6</td><td>Reserved. Read as 0.</td></tr>
<tr><td>5:4</td><td>Video Status Mux. These 2 bits are used to select 2 of the 8 possible palette bits (P7-P0) to be made available to be read via bits 5 and 4 of the Input Status Register 1 (ST01). The table below shows the possible choices.
<table>
<tr><th>Bit [5:4]</th><th>ST01 Bit 5</th><th>ST01 Bit 4</th></tr>
<tr><td>00</td><td>P2 (default)</td><td>P0 (default)</td></tr>
<tr><td>01</td><td>P5</td><td>P4</td></tr>
<tr><td>10</td><td>P3</td><td>P1</td></tr>
<tr><td>11</td><td>P7</td><td>P6</td></tr>
</table>
These bits are typically unused by current software; they are provided for EGA compatibility.</td></tr>
<tr><td>3:0</td><td>Enable Plane [3:0]. These 4 bits individually enable the use of each of the 4 memory planes in providing 1 of the 4 bits used in video output to select 1 of 16 possible</td></tr>
</table>

Bit	Description
	colors from the palette to be displayed. 0 = Disable the use of the corresponding memory plane in video output to select colors, forcing the bit that the corresponding memory plane would have provided to a value of 0. 1 = Enable the use of the corresponding memory plane in video output to select colors. AR12 is referred to in the VGA standard as the Color Plane Enable Register.

AR13 - Horizontal Pixel Panning Register

Address: Read at 3C1h and Write at 3C0h; (index=13h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:4	**Reserved.**
3:0	**Horizontal Pixel Shift 3-0.** This field holds a 4-bit value that selects the number of pixels by which the image is shifted horizontally to the left. This function is available in both text and graphics modes and allows for pixel panning. In text modes with a 9-pixel wide character box, the image can be shifted up to 9 pixels to the left. In text modes with an 8-pixel wide character box, and in graphics modes other than those with 256 colors, the image can be shifted up to 8 pixels to the left. A pseudo 9-bit mode is when the 9-dot character is selected but overridden by the VGA control bit. In standard VGA mode 13h (where bit 6 of the Mode Control Register, AR10, is set to 1 to support 256 colors), bit 0 of this register must remain set to 0, and the image may be shifted up to only 4 pixels to the left. In this mode, the number of pixels by which the image is shifted can be further controlled using bits 6 and 5 of the Preset Row Scan Register (CR08).

Number of Pixels Shifted				
Bits [3:0]	**9-dot**	**Pseudo 9-dot**	**8-dot**	**256-Color**
0	1	1	0	0
1	2	2	1	Undefined

AR14 - Color Select Register

Address: Read at 3C1h and Write at 3C0h; (index=14h)

Default: 0Uh (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:4	**Reserved.**
3:2	**Palette Bits P[7:6].** These are the 2 upper-most of the 8 bits that are used to map either text attributes or pixel color input values (for modes that use 16 colors) to the 256 possible colors contained in the palette. These 2 bits are common to all 16 sets of bits P5 through P0 that are individually supplied by Palette Registers 0-F (AR[00:0F]).
1:0	**Alternate Palette Bits P[5:4].** These 2 bits can be used as an alternate version of palette bits P5 and P4. Unlike the P5 and P4 bits that are individually supplied by Palette Registers 0-F (AR[00:0F]), these 2 alternate palette bits are common to all 16 of Palette Registers. Bit 7 of the Mode Control Register (AR10) is used to select between the use of either the P5 and P4 bits that are individually supplied by the 16 Palette Registers or these 2 alternate palette bits.

VGA Color Palette Registers

In devices that have multiple display pipes, there is one palette for each display pipe. These palettes are the same for VGA modes and non-VGA modes. Accesses through VGA register methods will read or write from the palette of the pipe selected through MMIO VGA control register.

For each palette, the color data stored in these 256 color data positions can be accessed only through a complex sub-addressing scheme, using a data register and two index registers. The Palette Data Register at address 3C9h is the data port. The Palette Read Index Register at address 3C7h and the Palette Write Index Register at address 3C8h are the two index registers. The Palette Read Index Register is the index register that is used to choose the color data position that is to be read from via the data port, while the Palette Write Index Register is the index register that is used to choose the color data position that is to be written to through the same data port. This arrangement allows the same data port to be used for reading from and writing to two different color data positions. Reading and writing the color data at a color data position involves three successive reads or writes since the color data stored at each color data position consists of three bytes.

To read a palette color data position, the index of the desired color data position must first be written to the Palette Read Index Register. Then all three bytes of data in a given color data position may be read at the Palette Data Register. The first byte read from the Palette Data Register retrieves the 8-bit value specifying the intensity of the red color component. The second and third bytes read are the corresponding 8-bit values for the green and blue color components respectively. After completing the third read operation, the Palette Read Index Register is automatically incremented so that the data of the next color data position becomes accessible for being read. This allows the contents of all of the 256 color data positions of the palette to be read in sequence. This is done by specifying only the index of the 0th color data position in the Palette Read Index Register, and then simply performing 768 successive reads from the Palette Data Register.

Writing a color data position, entails a very similar procedure. The index of the desired color data position must first be written to the Palette Write Index Register. Then all three bytes of data to specify a given color may be written to the Palette Data Register. The first byte written to the Palette Data Register specifies the intensity of the red color component, the second byte specifies the intensity for the green color component, and the third byte specifies the same for the blue color component. One important detail is that all three of these bytes must be written before the hardware will actually update these three values in the given color data position. When all three bytes have been written, the Palette Write Index Register is automatically incremented so that the data of the next color data position becomes accessible for being written. This allows the contents of all of the 256 color data positions of the palette to be written in sequence. This is done by specifying only the index of the 0th color data position in the Palette Write Index Register, and then simply performing 768 successive writes to the Palette Data Register.

DACMASK - Pixel Data Mask Register

Address: 3C6h

Default:
Undefined
Attributes:
Read/Write

Bit	Description
7:0	**Pixel Data Mask.** In indexed-color mode, the 8 bits of this register are logically ANDed with the 8 bits of pixel data received from the frame buffer for each pixel. The result of this ANDing process becomes the actual index used to select color data positions within the palette. This has the effect of limiting the choice of color data positions that may be specified by the incoming 8-bit data. 0 = Corresponding bit in the resulting 8-bit index being forced to 0. 1 = Allows the corresponding bit in the resulting index to reflect the actual value of the corresponding bit in the incoming 8-bit pixel data.

DACSTATE - DAC State Register

Address: 3C7h

Default:
00h
Attributes:
Read Only

Bit	Description
7:2	**Reserved.** Read as 0.
1:0	**DACState.** This field indicates which of the two index registers was most recently written. **Bits [1:0]** Index Register Indicated 00 = Palette Write Index Register at Address 3C7h (default) 01 = Reserved 10 = Reserved 11 = Palette Read Index Register at Address 3C8h

DACRX - Palette Read Index Register

Address: 3C7h

Default:
00h
Attributes:
Write Only

Bit	Description
7:0	**Palette Read Index.** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being read from via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been read. A write to this register will abort an uncompleted palette write sequence. This register allows access to the palette even when running non-VGA display modes.

DACWX - Palette Write Index Register

Address: 3C8h

Default:
00h
Attributes:
Write Only

Bit	Description
7:0	**Palette Write Index.** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being written via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been written. This register allows access to the palette even when running non-VGA display modes.

DACDATA - Palette Data Register

Address: 3C9h

Default:
Undefined
Attributes:
Read/Write

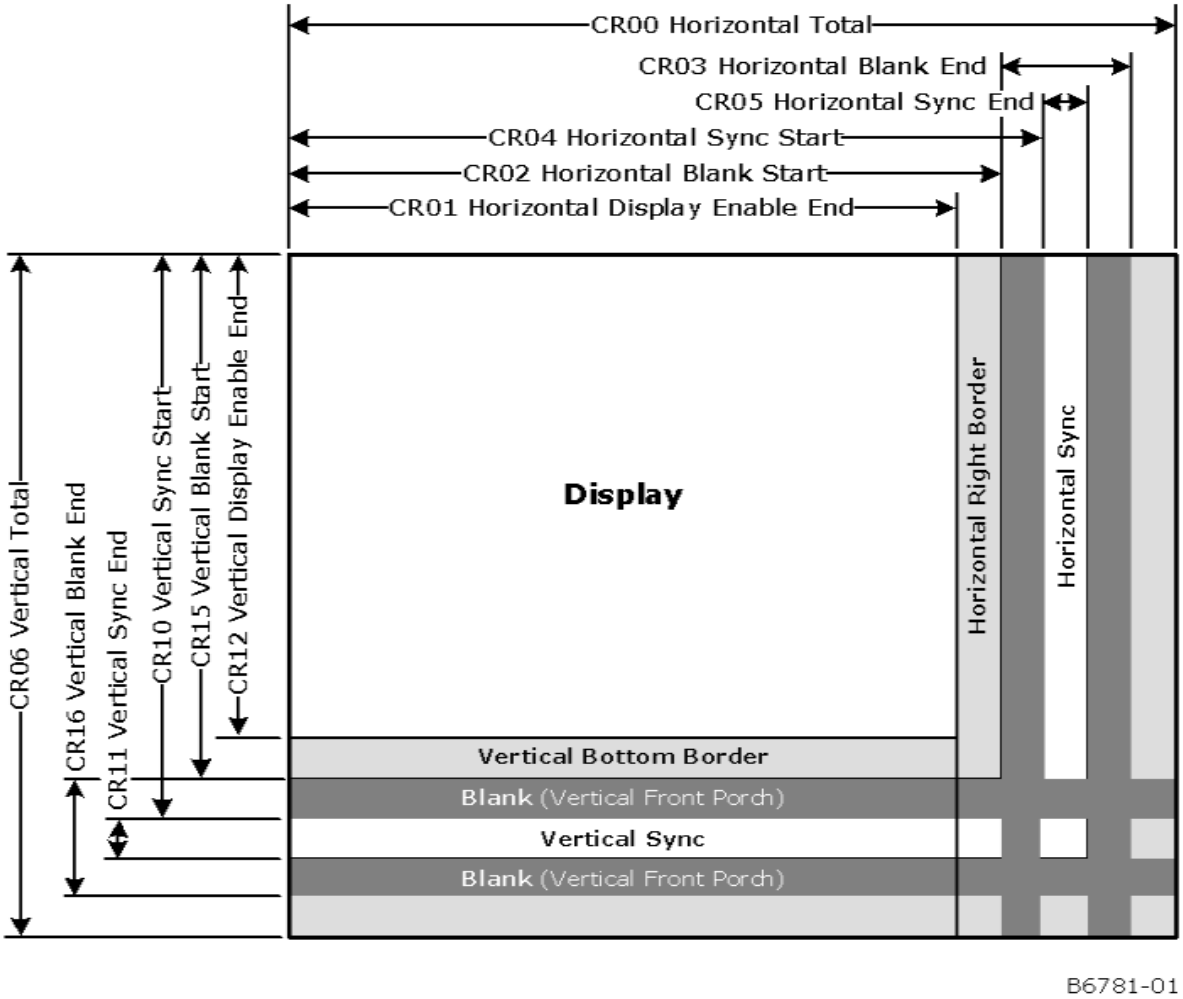
Bit	Description
7:0	**Palette Data.** This byte-wide data port provides read or write access to the three bytes of data of each color data position selected using the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX). The three bytes in each color data position are read or written in three successive read or write operations. The first byte read or written specifies the intensity of the red component of the color specified in the selected color data position. The second byte is for the green component, and the third byte is for the blue component. When writing data to a color data position, all three bytes must be written before the hardware will actually update the three bytes of the selected color data position. When reading or writing to a color data position, ensure that neither the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX) are written to before all three bytes are read or written. A write to either of these two registers causes the circuitry that automatically cycles through providing access to the bytes for red, green and blue components to be reset such that the byte for the red component is the one that will be accessed by the next read or write operation via this register. This register allows access to the palette even when running non-VGA display modes. Writes to the palette can cause sparkle if not done during inactive video periods. This sparkle is caused by an attempt to write and read the same address on the same cycle. Some devices contain anti-sparkle circuits which will substitute the previous pixel value for the read output.

CRT Controller Register

For native VGA modes, the CRTC registers determine the display timing that is to be used. In centered VGA modes, these registers determine the size of the VGA image that is to be centered in the larger timing generator defined rectangle.

The CRT controller registers are accessed by writing the index of the desired register into the CRT Controller Index Register at address 3B4h or 3D4h, depending on whether the graphics system is configured for MDA or CGA emulation. The desired register is then accessed through the data port for the CRT controller registers located at address 3B5h or 3D5h, again depending upon the choice of MDA or CGA emulation as per MSR[0].

The following figure shows display fields and dimensions and the particular CRxx register that provides the control.



Group 0 Protection: In the original VGA, CR[0:7] could be made write-protected by CR11[7]. In BIOS code, this write protection is set following each mode change. Other protection groups have no current use, and would not be used going forward by the BIOS or by drivers. They are the result of an industry fad some years ago to attempt to write protect other groups of registers; however, all such schemes were chip specific. Only the write protection (Group 0 Protection) is supported.

CRX - CRT Controller Index Register

Address: 3B4h/3D4h

Default:
0Uh (U=Undefined)
Attributes:
Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:0	**CRT Controller Index.** These 7 bits are used to select any one of the CRT controller registers to be accessed via the data port at location 3B5h or 3D5h, depending upon whether the graphics system is configured for MDA or CGA emulation.

CR00 - Horizontal Total Register

Address: 3B5h/3D5h (index=00h)

Default: 00h

Attributes:
Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Total.** This register is used to specify the total length of each scan line. This encompasses both the part of the scan line that is within the active display area and the part that is outside of it. Programming this register to a zero has the effect of stopping the fetching of display data. This field should be programmed with a value equal to the total number of character clocks within the entire length of a scan line, minus 5.

CR01 - Horizontal Display Enable End Register

Address: 3B5h/3D5h (index=01h)

Default: Undefined

Attributes:
Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Display Enable End.** This register is used to specify the end of the part of the scan line that is within the active display area relative to its beginning. In other words, this is the horizontal width of the active display area. This field should be programmed with a value equal to the number of character clocks that occur within the horizontal active display area, minus 1. Horizontal display

Bit	Description
	enable will go active at the beginning of each line during vertical active area, it will go inactive based on the programming of this register or the programming of the horizontal total (CR00) register. When this register value is programmed to a number that is larger than the total number of characters on a line, display enable will be active for all but the last character of the horizontal display line.

CR02 - Horizontal Blanking Start Register

Address: 3B5h/3D5h (index=02h)

Default: Undefined

Attributes:
Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Blanking Start.** This register is used to specify the beginning of the horizontal blanking period relative to the beginning of the active display area of a scan line. Horizontal blanking should always be set to start no sooner than after the end of horizontal active. This field should be programmed with a value equal to the number of character clocks that occur on a scan line from the beginning of the active display area to the beginning of the horizontal blanking.

CR03 - Horizontal Blanking End Register

Address: 3B5h/3D5h (index=03h)

Default: 1UUU UUUUb (U=Undefined)

Attributes:
Read/Write (Group 0 Protection)

Bit	Description
7	**Reserved.** Values written to this bit are ignored, and to maintain consistency with the VGA standard, a value of 1 is returned when this bit is read. At one time, this bit was used to enable access to certain light pen registers. At that time, setting this bit to 0 provided this access, but setting this bit to 1 was necessary for normal operation.
6:5	**Display Enable Skew Control.** Defines the degree to which the start and end of the active display area are delayed along the length of a scan line to compensate for internal pipeline delays. These 2 bits describe the delay in terms of a number character clocks. **Bit [6:5]** Amount of Delay 00 = no delay

Bit	Description
	01 = delayed by 1 character clock 10 = delayed by 2 character clocks 11 = delayed by 3 character clocks
4:0	**Horizontal Blanking End Bits [4:0].** This field provides the 5 least significant bits of a 6-bit value that specifies the end of the blanking period relative to its beginning on a single scan line. Bit 7 of the Horizontal Sync End Register (CR05) supplies the most significant bit. This 6-bit value should be programmed to be equal to the least significant 6 bits of the result of adding the length of the blanking period in terms of character clocks to the value specified in the Horizontal Blanking Start Register (CR02). End of blanking should occur before horizontal total.

CR04 - Horizontal Sync Start Register

Address: 3B5h/3D5h (index=04h)

Default: Undefined

Attributes:
Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Sync Start** This register is used to specify the position of the beginning of the horizontal sync pulse relative to the start of the active display area on a scan line. This field should be set equal to the number of character clocks that occur from beginning of the active display area to the beginning of the horizontal sync pulse on a single scan line. Horizontal sync should always occur at least 2 clocks after the start of horizontal blank and 2 clocks before the end of horizontal blank. The actual start of sync will also be affected by both the horizontal sync skew register field and whether it is a text or graphics mode.

CR05 - Horizontal Sync End Register

Address: 3B5h/3D5h (index=05h)

Default: 00h

Attributes:
Read/Write (Group 0 Protection)

Bit	Description
7	**Horizontal Blanking End Bit 5.** This bit provides the most significant bit of a 6-bit value that specifies the end of the horizontal blanking period relative to its beginning. Bits [4:0] of Horizontal Blanking End Register (CR03) supplies the 5 least significant bits.

Bit	Description
	See CR03[4:0] for further details. This 6-bit value should be set to the least significant 6 bits of the result of adding the length of the blanking period in terms of character clocks to the value specified in the Horizontal Blanking Start Register (CR02).
6:5	**Horizontal Sync Delay.** This field defines the degree to which the start and end of the horizontal sync pulse are delayed to compensate for internal pipeline delays. This capability is supplied to implement VGA compatibility. These field describes the delay in terms of a number character clocks. **Bit [6:5] — Amount of Delay** 00 — no delay 01 — delayed by 1 character clock 10 — delayed by 2 character clocks 11 — delayed by 3 character clocks
4:0	**Horizontal Sync End.** This field provides the 5 least significant bits of a 5-bit value that specifies the end of the horizontal sync pulse relative to its beginning. A value equal to the 5 least significant bits of the horizontal character counter value at which time the horizontal retrace signal becomes inactive (logical 0). Thus, this 5-bit value specifies the width of the horizontal sync pulse. To obtain a retrace signal of W, the following algorithm is used: Value of Horizontal Sync start Register (CR04) + width of horizontal retrace signal in character clock units = 5 bit result to be programmed in this field

CR06 - Vertical Total Register

Address: 3B5h/3D5h (index=06h)

Default: 00h

Attributes:
Read/Write (Group 0 Protection)

Bit	Description
7:0	**Vertical Total Bits [7:0].** This field provides the 8 least significant bits of either a 10-bit or 12-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. In standard VGA modes, the vertical total is specified with a 10-bit value. The 8 least significant bits of this value are supplied by these 8 bits of this register, and the 2 most significant bits are supplied by bits 5 and 0 of the Overflow Register (CR07).

CR07 - Overflow Register (Vertical)

Address: 3B5h/3D5h (index=07h)

Default: UU0U UUU0b (U=Undefined)

Attributes:

Read/Write (Group 0 Protection on bits [7:5, 3:0])

Bit	Description
7	**Vertical Sync Start Bit 9.** The vertical sync start is a 10-bit that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Sync Start Register (CR10), and the most and second-most significant bits are supplied by this bit and bit 2, respectively, of this register. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the start of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.
6	**Vertical Display Enable End Bit 9.** The vertical display enable end is a 10-bit that specifies the number of the last scan line within the active display area. In standard VGA modes, the vertical display enable end is specified with a 10-bit value. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Display Enable End Register (CR12), and the most and second-most significant bits are supplied by this bit and bit 1, respectively, of this register. This 10-bit value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area, minus 1.
5	**Vertical Total Bit 9.** The vertical total is a 10-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Total Register (CR06), and the most and second-most significant bits are supplied by this bit and bit 0, respectively, of this register. This 10-bit value should be programmed equal to the total number of scan lines, minus 2.
4	**Line Compare Bit 8.** This bit provides the second most significant bit of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 6 of the Maximum Scan Line Register (CR09) supplies the most significant bit, and bits 7-0 of the Line Compare Register (CR18) supply the 8 least significant bits. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and

Bit	Description
	bottom part, with the image in the top part being repeated in the bottom part. When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display what data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display what data exists in the frame buffer starting at the first byte of the frame buffer.
3	**Vertical Blanking Start Bit 8.** The vertical blanking start is a 10-bit that specifies the beginning of the vertical blanking period relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Blanking Start Register (CR15), and the most and second-most significant bits are supplied by bit 5 of the Maximum Scan Line Register (CR09) and this bit of this register, respectively. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the beginning of the blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical blanking period begins.
2	**Vertical Sync Start Bit 8.** The vertical sync start is a 10-bit value that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Sync Start Register (CR10), and the most and second-most significant bits are supplied by bit 7 and this bit, respectively, of this register. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the start of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.
1	**Vertical Display Enable End Bit 8.** The vertical display enable end is a 10-bit value that specifies the number of the last scan line within the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Display Enable End Register (CR12), and the two most significant bits are supplied by bit 6 and this bit, respectively, of this register. This 10-bit or value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area, minus 1.
0	**Vertical Total Bit 8.** The vertical total is a 10-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Total Register (CR06), and the most and second-most significant bits

Bit	Description
	are supplied by bit 5 and this bit, respectively, of this register. This 10-bit value should be programmed to be equal to the total number of scan lines, minus 2.

CR08 - Preset Row Scan Register

Address: 3B5h/3D5h (index=08h)

Default: 0UUU UUUUb (U=Undefined)

Attributes:
Read/Write

Bit	Description
7	**Reserved.** Read as 0s.
6:5	**Byte Panning.** This field holds a 2-bit value that selects number of bytes (up to 3) by which the image is shifted horizontally to the left on the screen. This function is available in both text and graphics modes. In text modes with a 9-pixel wide character box, the image can be shifted up to 27 pixels to the left, in increments of 9 pixels. In text modes with an 8-pixel wide character box, and in all standard VGA graphics modes, the image can be shifted up to 24 pixels to the left, in increments of 8 pixels. When the Nine dot disable bit of the VGA control register is set, the pixel shift will be equivalent to the 8-dot mode. The image can be shifted still further, in increments of individual pixels, through the use of bits [3:0] of the Horizontal Pixel Panning Register (AR13).
4:0	**Starting Row Scan Count.** This field specifies which horizontal line of pixels within the character boxes of the characters used on the top-most row of text on the display will be used as the top-most scan line. The horizontal lines of pixels of a character box are numbered from top to bottom, with the top-most line of pixels being number 0. If a horizontal line of the these character boxes other than the top-most line is specified, then the horizontal lines of the character box above the specified line of the character box will not be displayed as part of the top-most row of text characters on the display. Normally, the value specified by these 5 bits should be 0, so that all of the horizontal lines of

Number of Pixels Shifted		
Bit [6:5]	**9-Pixel Text**	**8-Pixel Text & Graphics**
00	0	0
01	9	8
10	18	16
11	27	24

Bit	Description
	pixels within these character boxes will be displayed in the top-most row of text, ensuring that the characters in the top-most row of text do not look as though they have been cut off at the top.

CR09 - Maximum Scan Line Register

Address: 3B5h/3D5h (index=09h)

Default: 00h

Attributes:
Read/Write

Bit	Description
7	**Double Scanning Enable.** 0 = Disable. When disabled, the clock to the row scan counter is equal to the horizontal scan rate. This is the normal setting for many of the standard VGA modes. 1 = Enable. When enabled, the clock to the row scan counter is divided by 2. This is normally used to allow CGA-compatible modes that have only 200 scan lines of active video data to be displayed as 400 scan lines (each scan line is displayed twice).
6	**Line Compare Bit 9.** This bit provides the most significant bit of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 4 of the Overflow Register (CR07) supplies the second most significant bit, and bits 7-0 of the Line Compare Register (CR18) supply the 8 least significant bits. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display whatever data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display whatever data exists in the frame buffer starting at the first byte of the frame buffer.
5	**Vertical Blanking Start Bit 9.** The vertical blanking start is a 10-bit value that specifies the beginning of the vertical blanking period relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Blanking Start Register (CR15), and the most and second-most significant bits are supplied by this bit and bit 3 of the Overflow Register (CR07), respectively. This 10-bit value should be programmed to be equal to the number of scan line from

Bit	Description
	the beginning of the active display area to the beginning of the blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical blanking period begins.
4:0	**Starting Row Scan Count.** This field provides all 5 bits of a 5-bit value that specifies the number of scan lines in a horizontal row of text. This value should be programmed to be equal to the number of scan lines in a horizontal row of text, minus 1.

CR0A - Text Cursor Start Register

Address: 3B5h/3D5h (index=0Ah)

Default: 00UU UUUUb (U=Undefined)

Attributes:
Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5	**Text Cursor Off.** This text cursor exists only in text modes, so this register is entirely ignored in graphics modes. 0 = Enables the text cursor. 1 = Disables the text cursor.
4:0	**Text Cursor Start.** This field specifies which horizontal line of pixels in a character box is to be used to display the first horizontal line of the cursor in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the first horizontal line of pixels on which the cursor is to be shown.

CR0B - Text Cursor End Register

Address: 3B5h/3D5h (index=0Bh)

Default: 0UUU UUUUb (U=Undefined)

Attributes:
Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:5	**Text Cursor Skew.** This field specifies the degree to which the start and end of each horizontal line of pixels making up the cursor is delayed to compensate for internal

Bit	Description
	pipeline delays. These 2 bits describe the delay in terms of a number character clocks. **Bit [6:5]** Amount of Delay 00 = No delay 01 = Delayed by 1 character clock 10 = Delayed by 2 character clocks 11 = Delayed by 3 character clocks
4:0	**Text Cursor End.** This field specifies which horizontal line of pixels in a character box is to be used to display the last horizontal line of the cursor in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the last horizontal line of pixels on which the cursor is to be shown.

CR0C - Start Address High Register

Address: 3B5h/3D5h (index=0Ch)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Start Address Bits [15:8].**This register provides either bits 15 through 8 of a 16-bit value that specifies the memory address offset from the beginning of the frame buffer at which the data to be shown in the active display area begins. (default is 0) In standard VGA modes, the start address is specified with a 16-bit value. The eight bits of this register provide the eight most significant bits of this value, while the eight bits of the Start Address Low Register (CR0D) provide the eight least significant bits.

CR0D - Start Address Low Register

Address: 3B5h/3D5h (index=0Dh)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Start Address Bits [7:0]** This register provides either bits 7 through 0 of a 16 bit value that specifies the memory address offset from the beginning of the frame buffer at

Bit	Description
	which the data to be shown in the active display area begins. (default is 0) In standard VGA modes the start address is specified with a 16-bit value. The eight bits of the Start Address High Register (CR0C) provide the eight most significant bits of this value, while the eight bits of this register provide the eight least significant bits.

CR0E - Text Cursor Location High Register

Address: 3B5h/3D5h (index=0Eh)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Text Cursor Location Bits [15:8].** This field provides the 8 most significant bits of a 16-bit value that specifies the address offset from the beginning of the frame buffer at which the text cursor is located. Bit 7:0 of the Text Cursor Location Low Register (CR0F) provide the 8 least significant bits.

CR0F - Text Cursor Location Low Register

Address: 3B5h/3D5h (index=0Fh)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Text Cursor Location Bits [7:0].** This field provides the 8 least significant bits of a 16-bit value that specifies the address offset from the beginning of the frame buffer at which the text cursor is located. Bits 7:0 of the Text Cursor Location High Register (CR0E) provide the 8 most significant bits.

CR10 - Vertical Sync Start Register

Address: 3B5h/3D5h (index=10h)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Vertical Sync Start Bits [7:0].** This register provides the 8 least significant bits of a 10-bit that specifies the beginning of the vertical sync pulse relative to the

Bit	Description
	beginning of the active display area of a screen. In standard VGA modes, this value is described in 10 bits with bits [7,2] of the Overflow Register (CR07) supplying the 2 most significant bits. This 10-bit value should equal the vertical sync start in terms of the number of scan lines from the beginning of the active display area to the beginning of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.

CR11 - Vertical Sync End Register

Address: 3B5h/3D5h (index=11h)

Default: 0U00 UUUUb (U=Undefined)

Attributes:
Read/Write

Bit	Description
7	**Protect Registers [0:7].** The ability to write to Bit 4 of the Overflow Register (CR07) is not affected by this bit (i.e., bit 4 of the Overflow Register is always writeable). 0 = Enable writes to registers CR[00:07]. (default) 1 = Disable writes to registers CR[00:07].
6	**Reserved.** In the VGA standard, this bit was used to switch between 3 and 5 frame buffer refresh cycles during the time required to draw each horizontal line.
5	**Vertical Interrupt Enable.** This bit is reserved for compatibility only. While this bit may be written or read, it's value will have no effect. VGA does not provide an interrupt signal which would be connected to an input of the system's interrupt controller. Bit 7 of Input Status Register 0 (ST00) originally indicated the status of the vertical retrace interrupt. 0 = Enable the generation of an interrupt at the beginning of each vertical retrace period. 1 = Disable the generation of an interrupt at the beginning of each vertical retrace period.
4	**Vertical Interrupt Clear.** This is reserved for compatibility only. VGA does not provide an interrupt signal which would be connected to an input of the system's interrupt controller. 0 = Setting this bit to 0 clears a pending vertical retrace interrupt. This bit must be set back to 1 to enable the generation of another vertical retrace interrupt.

Bit	Description
3:0	**Vertical Sync End.** This 4-bit field provides a 4-bit value that specifies the end of the vertical sync pulse relative to its beginning. This 4-bit value should be set to the least significant 4 bits of the result of adding the length of the vertical sync pulse in terms of the number of scan lines that occur within the length of the vertical sync pulse to the value that specifies the beginning of the vertical sync pulse (see the description of the Vertical Sync Start Register for more details).

CR12 - Vertical Display Enable End Register

Address: 3B5h/3D5h (index=12h)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Vertical Display Enable End Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the number of the last scan line within the active display area. In standard VGA modes, this value is described in 10 bits with bits [6,1] of the Overflow Register (CR07) supplying the two most significant bits. This 10-bit value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area,minus 1.

CR13 - Offset Register

Address: 3B5h/3D5h (index=13h)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Offset Bits [7:0].** This register provides either all 8 bits of an 8-bit value that specifies the number of words or DWords of frame buffer memory occupied by each horizontal row of characters. Whether this value is interpreted as the number of words or DWords is determined by the settings of the bits in the Clocking Mode Register (SR01). In standard VGA modes, the offset is described with an 8-bit value, all the bits of which are provided by this register. This 8-bit value should be programmed to be equal to either the number of words or DWords (depending on the setting of the bits in the Clocking Mode Register, SR01) of frame buffer memory that is occupied by each horizontal row of characters.

CR14 - Underline Location Register

Address: 3B5h/3D5h (index=14h)

Default: 0UUU UUUUb (U=Undefined)

Attributes:
Read/Write

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>7</td><td>Reserved. Read as 0.</td></tr>
<tr><td>6</td><td>DWord Mode.
0 = Frame buffer addresses are interpreted by the frame buffer address decoder as being either byte addresses or word addresses, depending on the setting of bit 6 of the CRT Mode Control Register (CR17).
1 = Frame buffer addresses are interpreted by the frame buffer address decoder as being DWord addresses, regardless of the setting of bit 6 of the CRT Mode Control Register (CR17).
This bit is used in conjunction with bits 6 and 5 of the CRT Mode Control Register (CR17) to select how frame buffer addresses from the CPU are interpreted by the frame buffer address decoder as shown below:
<table>
<tr><th>CR14[6]</th><th>CR17[6]</th><th>Addressing Mode</th></tr>
<tr><td>0</td><td>0</td><td>Word Mode</td></tr>
<tr><td>0</td><td>1</td><td>Byte Mode</td></tr>
<tr><td>1</td><td>0</td><td>DWord Mode</td></tr>
<tr><td>1</td><td>1</td><td>DWord Mode</td></tr>
</table></td></tr>
<tr><td>5</td><td>Count By 4.
0 = The memory address counter is incremented either every character clock or every other character clock, depending upon the setting of bit 3 of the CRT Mode Control Register.
1 = The memory address counter is incremented either every 4 character clocks or every 2 character clocks, depending upon the setting of bit 3 of the CRT Mode Control Register. . This is used in mode x13 to allow for using all four planes.
This bit is used in conjunction with bit 3 of the CRT Mode Control Register (CR17) to select the number of character clocks are required to cause the memory address counter to be incremented as shown, below:
<table>
<tr><th>CR14[5]</th><th>CR17[3]</th><th>Addressing Incrementing Interval</th></tr>
<tr><td>0</td><td>0</td><td>every character clock</td></tr>
<tr><td>0</td><td>1</td><td>every 2 character clocks</td></tr>
<tr><td>1</td><td>0</td><td>every 4 character clocks</td></tr>
<tr><td>1</td><td>1</td><td>every 2 character clocks</td></tr>
</table></td></tr>
<tr><td>4:0</td><td>Underline Location. This field specifies which horizontal line of pixels in a character box is to be used to display a character underline in text mode. The horizontal lines of pixels in a character box are numbered</td></tr>
</table>

Bit	Description
	from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the horizontal line on which the character underline mark is to be shown.

CR15 - Vertical Blanking Start Register

Address: 3B5h/3D5h (index=15h)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Vertical Blanking Start Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the beginning of the vertical blanking period relative to the beginning of the active display area of the screen. In standard VGA modes, the vertical blanking start is specified with a 10-bit value. The most and second-most significant bits of this value are supplied by bit 5 of the Maximum Scan Line Register (CR09) and bit 3 of the Overflow Register (CR07), respectively. This 10-bit value should be programmed to be equal the number of scan lines from the beginning of the active display area to the beginning of the vertical blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which vertical blanking begins.

CR16 - Vertical Blanking End Register

Address: 3B5h/3D5h (index=16h)

Default: Undefined

Attributes:
Read/Write

This register provides a 8-bit value that specifies the end of the vertical blanking period relative to its beginning.

Bit	Description
7:0	**Vertical Blanking End Bits [7:0].** This 8-bit value should be set equal to the least significant 8 bits of the result of adding the length of the vertical blanking period in terms of the number of scan lines that occur within the length of the vertical blanking period to the value that specifies the beginning of the vertical blanking period (see the description of the Vertical Blanking Start Register for details).

CR17 - CRT Mode Control

Address: 3B5h/3D5h (index=17h)

Default: 0UU0 UUUUb (U=Undefined)

Attributes:
Read/Write

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>7</td><td>CRT Controller Reset. This bit has no effect except in native VGA modes (non-centered).
0 = Forces horizontal and vertical sync signals to be inactive. No other registers or outputs are affected.
1 = Permits normal operation.</td></tr>
<tr><td>6</td><td>Word Mode or Byte Mode.
0 = The memory address counter's output bits are shifted by 1 bit position before being passed on to the frame buffer address decoder such that they are made into word-aligned addresses when bit 6 of the Underline Location Register (CR17) is set to 0.
1 = The memory address counter's output bits remain unshifted before being passed on to the frame buffer address decoder such that they remain byte-aligned addresses when bit 6 of the Underline Location Register (CR17) is set to 0.
This bit is used in conjunction with bits 6 and 5 of the CRT Mode Control Register (CR17) to control how frame buffer addresses from the memory address counter are interpreted by the frame buffer address decoder as shown below:
<table>
<tr><th>CR14[6]</th><th>CR17[6]</th><th>Address Mode</th></tr>
<tr><td>0</td><td>0</td><td>Word Mode - Addresses from the memory address counter are shifted once to become word-aligned</td></tr>
<tr><td>0</td><td>1</td><td>Byte Mode - Addresses from the memory address counter are not shifted</td></tr>
<tr><td>1</td><td>0</td><td>DWord Mode - Addresses from the memory address counter are shifted twice to become DWord-aligned</td></tr>
<tr><td>1</td><td>1</td><td>DWord Mode - Addresses from the memory address counter are shifted twice to become DWord-aligned</td></tr>
</table></td></tr>
<tr><td>5</td><td>Address Wrap. This bit is only effective when word mode is made active by setting bit 6 in both the Underline Location Register and this register to 0.
0 = Wrap frame buffer address at 16 KB. This is used in CGA-compatible modes.
1 = No wrapping of frame buffer addresses.</td></tr>
</table>

Bit	Description
4	**Reserved.** Read as 0.
3	**Count By 2.** This bit is used in conjunction with bit 5 of the Underline Location Register (CR14) to select the number of character clocks are required to cause the memory address counter to be incremented. 0 = The memory address counter is incremented either every character clock or every 4 character clocks, depending upon the setting of bit 5 of the Underline Location Register. 1 = The memory address counter is incremented either every other clock. CR14[5] CR17[3] Address Incrementing interval 0 0 every character clock 0 1 every 2 character clocks 1 0 every 4 character clocks 1 1 every 2 character clocks
2	**Horizontal Retrace Select.** This bit provides a way of effectively doubling the vertical resolution by allowing the vertical timing counter to be clocked by the horizontal retrace clock divided by 2 (usually, it would be undivided). 0 = The vertical timing counter is clocked by the horizontal retrace clock. 1 = The vertical timing counter is clocked by the horizontal retrace clock divided by 2.
1	**Select Row Scan Counter.** 0 = A substitution takes place, where bit 14 of the 16-bit memory address generated of the memory address counter (after the stage at which these 16 bits may have already been shifted to accommodate word or DWord addressing) is replaced with bit 1 of the row scan counter at a stage just before this address is presented to the frame buffer address decoder. 1 = No substitution takes place. See following tables.
0	**Compatibility Mode Support.** 0 = A substitution takes place, where bit 13 of the 16-bit memory address generated of the memory address counter (after the stage at which these 16 bits may have already been shifted to accommodate word or DWord addressing) is replaced with bit 0 of the row scan counter at a stage just before this address is presented to the frame buffer address decoder. 1 = No substitution takes place. See following tables.

The following tables show the possible ways in which the address bits from the memory address counter can be shifted and/or reorganized before being presented to the frame buffer address decoder. First, the address bits generated by the memory address counter are reorganized, if need be, to accommodate

byte, word or DWord modes. The resulting reorganized outputs (MAOut15-MAOut0) from the memory address counter may also be further manipulated with the substitution of bits from the row scan counter (RSOut1 and RSOut0) before finally being presented to the input bits of the frame buffer address decoder (FBIn15-FBIn0).

CR18 - Line Compare Register

Address: 3B5h/3D5h (index=18h)

Default: Undefined

Attributes:
Read/Write

Bit	Description
7:0	**Line Compare Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 6 of the Maximum Scan Line Register (CR09) supplies the most significant bit, and bit 4 of the Overflow Register (CR07) supplies the second most significant bit. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. (This register is only used in split screening modes, and this is not a problem because split screening is not actually used for extended modes. As a result, there is no benefit to extending the existing overflow bits for higher resolutions.) When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described

Bit	Description
	earlier, but with the top and bottom parts displaying different data. The top part will display whatever data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display whatever data exists in the frame buffer starting at the first byte of the frame buffer.

CR22 - Memory Read Latch Data Register

Address: 3B5h/3D5h (index=22h)

Default: 00h

Attributes:
Read Only

Bit	Description
7:0	**Memory Read Latch Data.** This field provides the value currently stored in 1 of the four memory read latches. Bits 1 and 0 of the Read Map Select Register (GR04) select which of the four memory read latches may be read via this register.

CR24 - Toggle State of Attribute Controller Register

Address: 3B5h/3D5h (index=24h)

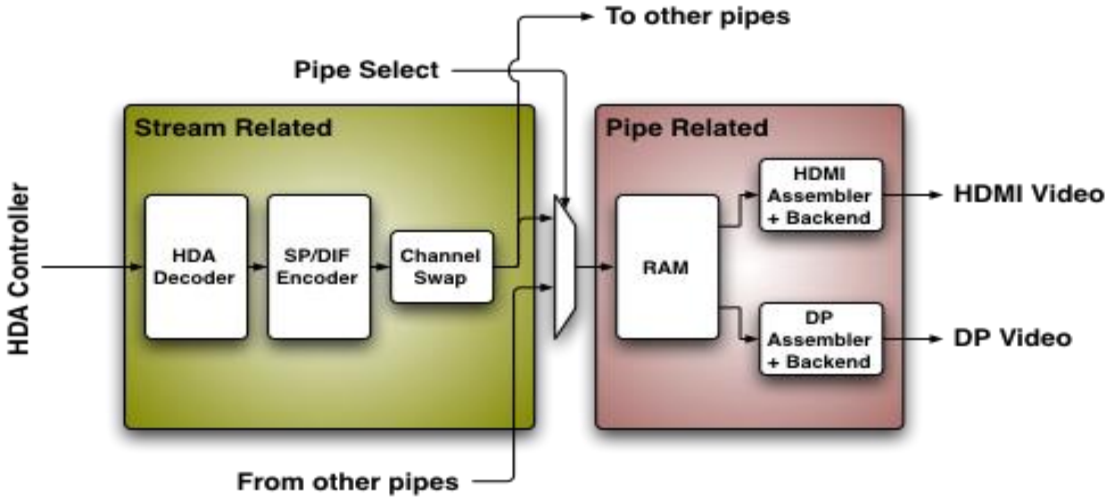
Default: 00h

Attributes:
Read Only

Bit	Description
7	**Toggle Status.** Indicates where the last write to attribute register was to: 0 = index port 1 = data port
6:0	**Reserved.** Read as 0.

Display Audio Codec Verbs

Block Diagram



Codec Node Hierarchy

The diagram below shows the hierarchy of the internal codec. The codec is presented as a single codec with multiple endpoints. By operating as a single codec, only one driver needs to be loaded on the system.

Inside the codec are three "converter widgets" and three "pin widgets", responsible for taking data from HD Audio DMA engines and placing into an HDMI/DP stream. Each pin widget has a 1-1 connection to a converter widget (as indicated by the dotted lines in the diagram).

NID = 8
Vendor Widget

Programming

Programming of the codec is performed by "verbs" as described in the HD Audio specification. These verbs travel over the internal HD Audio link at a rate of 1 verb per frame. A verb can either come from the CORB, with responses using the RIRB, or using an immediate command and response mechanism (ICR). Device 2 contains its own copy of an ICR mechanism as a back-door into the audio codec.

15:00	<value in table below>	**Device ID (DID):** Indicates the 16-bit Device ID values used to identify the codec to the PnP subsystem.

Device ID
2812h

Parameter 02h: RID - Revision ID

Bit	Reset	Description
31:24	*0*	*Reserved*
23:20	1h	**Major Revision (MJR):** Indicates the major revision number (left of the decimal) of the High Definition Audio Specification to which the codec is fully compliant.
19:16	0h	**Minor Revision (MNR):** Indicates the minor revision number (right of the decimal) or "dot number" of the High Definition Audio Specification to which the codec is fully compliant.
15:08	00h	**Revision ID (RID):** Indicates the vendor's revision number for this given Device ID.
07:00	00h	**Stepping ID (SID):** Indicates optional vendor stepping number within the revision.

Parameter 04h: PARAM_SNC - Subordinate Node Count

Bit	Reset	Description
31:24	*0*	*Reserved*
23:16	0h	**Starting Node Number (SNN):** Indicates the first sub-node's ID is 01h.
15:08	00h	Reserved
07:00	01h	**Total Number of Nodes (TNN):** Indicates one sub-node

F37h GET CCF - Get Current Clock Frequency

Bits	Default	Description
31:6	0	*Reserved*
05	0	**Current Clock 192 MHz (C192)**: Indicates the current clock is 192 MHz. Reserved for Display Codec
04	1	**Current Clock 96 MHz (C96)**: Indicates the current clock is 96 MHz.
03	0	**Current Clock 48 MHz (C48)**: Indicates the current clock is 48 MHz.
02	0	**Current Clock 24 MHz (C24)**: Indicates the current clock is 24 MHz. Reserved for Display Codec
01	0	**Current Clock 12 MHz (C12)**: Indicates the current clock is 12 MHz. Reserved for Display Codec
00	0	**Current Clock 6 MHz (C6)**: Indicates the current clock is 6 MHz. Reserved for Display Codec

Node ID 01h Audio Function Group Verbs

Set Verb	Get Verb	Symbol	Name
-	F00h	GET PARAM	Get Parameters
705h	F05h	SET_PS / GET_PS	Set Power State
-	F20h	GET_SSID	Get Subsystem ID
720h	F20h	SET_SSID0	Set/Get Subsystem ID
721h	F21h	SET_SSID1	Set/Get Subsystem ID
722h	F22h	SET_SSID2	Set//Get Subsystem ID
723h	F23h	SET_SSID3	Set/Get Subsystem ID

Set Verb	Get Verb	Symbol	Name
724h	F24h	SET CCF	Set/Get Current Clock Frequency

F00h Get Parameters

Parameter	Symbol	Register Name
04h	PARAM_SNC	Subordinate Node Count
05h	PARAM_FGT	Function Group Type
08h	PARAM_FGC	Function Group Capabilities
0Fh	PARAM SPS	Supported Power States

Parameter 04h: PARAM_SNC - Subordinate Node Count

Bit	Reset	Description
31:24	*0*	*Reserved*
23:16	03h	**Start Node Number (SNN):** Indicates the start node number of widget or functional nodes in the Functional Group.
15:08	*0*	*Reserved*
07:00	07h	**Total Number of Nodes (TNN):** Indicates 7 widgets in the Functional Group. (HDMI/DP converters (3) + HDMI/DP pins (3) + Vendor Defined Widget (1)). If Wigig is enabled in the vendor defined widget then the total number of nodes should be reported as 08h. Default for D11 is 9 [HDMI/DP converters (4) + HDMI/DP pins (5)]. If wireless widgets are enabled then total is 10 or 11. Default for D11p5 is 13 [HDMI/DP converters (4) + HDMI/DP pins (9)]. If wireless widgets are enabled then total is 14 or 15.

Parameter 05h: PARAM_FGT - Function Group Type

Bit	Reset	Description
31:09	*0*	*Reserved*
08	0	**Unsolicited Capable (UC):** Not capable of generating an unsolicited response.
07:00	01h	**Node Type (NT):** Indicates Audio Function Group.

Parameter 08h: PARAM_FGC - Function Group Capability

Bit	Reset	Description
31:04	*0*	*Reserved*
03:00	00h	**Output Delay (OD)**Output Delay.

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30	1	**Clock Stop (CS):** Indicates support for D3 when clock is stopped.
29:04	*0*	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

Parameter 16h: PARAM_A2CAP - Azalia 2 Capabilities

Bits	Reset	Description
31:17	*0*	*Reserved*
16	0	**Independent Codec Clock (ICC):** When set, this indicates that the codec generates its own clock, which may drift from the link clock. When cleared, the codec's clock is locked to the link clock.
15:06	*0*	*Reserved*
05	*0*	*Reserved for 192 MHz support.*
04	1	**96MHz Supported (S96):** Indicates 96 MHz clock is supported.
03	1	**48MHz Supported (S48):** Indicates 48 MHz clock is supported.This bit must always be set.
02	0	**24MHz Supported (S24):** Indicates 24 MHz clock is supported. Reserved for Display Codec
01	0	**12MHz Supported (S12):** Indicates 12 MHz clock is supported. Reserved for Display Codec
00	0	**6MHz Supported (S6)**Indicates 6 MHz clock is supported. Reserved for Display Codec

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Default values will not be changed. This bit will report 0 in all cases.
09	1	**Clock Stop OK (CSOK):** Clock stopping in D3 is OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved

Bits	Reset	Description
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

F20h GET SSID - Get Subsystem ID0

Bits	Reset	Description
31:00	80860101h	**Subsystem ID (SSID):** Reports the sub-system ID set via SET_SSIDx verbs.

720h SET SSID0 - Set Subsystem ID0

Bits	Description
07:00	Subsystem ID Bits [7:0]

721h SET SSID1 - Set Subsystem ID1

Bits	Description
07:00	Subsystem ID Bits [15:8]

722h SET SSID2 - Set Subsystem ID2

Bits	Description
07:00	Subsystem ID Bits [23:16]

723h SET SSID3 - Set Subsystem ID3

Bits	Description
07:00	Subsystem ID Bits [31:24]

724h SET CCF - Set Current Clock Frequency

Bits	Description
07:06	Reserved
05	**Set Clock 192 MHz (S192)**: Set clock to 192 MHz.
04	**Set Clock 96 MHz (S96)**: Set clock to 96 MHz
03	**Set Clock 48 MHz (S48)**: Set clock to 48 MHz
02	**Set Clock 24 MHz (S24)**: Set clock to 24 MHz
01	**Set Clock 12 MHz (S12)**: Set clock to 12 MHz
00	**Set Clock 6 MHz (S6)**: Set clock to 6 MHz

F24h GET CCF - Get Current Clock Frequency

Bits	Bits	Description
31:06	0	*Reserved*
05	0	**Current Clock 192 MHz (C192)**: Indicates the current clock is 192 MHz.
04	0	**Current Clock 96 MHz (C96)**: Indicates the current clock is 96 MHz.
03	0	**Current Clock 48 MHz (C48)**: Indicates the current clock is 48 MHz.
02	0	**Current Clock 24 MHz (C24)**: Indicates the current clock is 24 MHz.
01	0	**Current Clock 12 MHz (C12)**: Indicates the current clock is 12 MHz.
00	0	**Current Clock 6 MHz (C6)**: Indicates the current clock is 6 MHz.

7FFh SET Function Group Reset

Bits	Reset	Description
07:00	00h	The Function Reset command causes the functional unit, and all widgets associated with the functional unit, to return to their power-on reset values. Note that some controls such as the Configuration Default controls should not be reset with this command. It is also possible that certain other controls, such as Caller-ID, should not be reset. This command does not affect the Link interface logic, which must be reset with the link RST# signal. Therefore, a codec must not initiate a Status Change request on the link.

Audio Output Convertor Widget Verbs

Verb	Symbol	Verb Name
2h	SET_SDF	Set Stream Descriptor Format
Ah	GET_SDF	Get Stream Descriptor Format
F00h	GET_PARAM	Get Parameters
705h	SET_PS	Set Power State
F05h	GET_PS	Get Power State
706h	SET_CSID	Set Channel and Stream ID
F06h	GET_CSID	Get Channel and Stream ID
F0Dh	SET_DC1	Get Digital Converter
70Dh	SET_DC1	Set Digital Converter 1
70Eh	SET_DC2	Set Digital Converter 2
73Eh	SET_DC3	Set Digital Converter 3

Verb	Symbol	Verb Name
73Fh	SET_DC4	Set Digital Converter 4
72Dh	SET_CCC	Set Converter Channel Count
F2Dh	GET_CCC	Get Converter Channel Count

2hAh SETGET_SDF - SetGET Stream Descriptor Format

Bits	Reset	Description
31:15	0	Reserved
14	0	**Sample Base Rate (SBR):**
13:11	000	**Sample Base Rate Multiplier (SBRM):**
10:08	000	**Sample Base Rate Divisor (SBRD):**
07	0	Reserved
06:04	011	**Bits / Sample (BPS):** • 001b: Data is packed in memory in 16 bit containers on 16 bit boundaries • 010b: Data is packed in memory in 20 bit containers on 32 bit boundaries • 011b: Data is packed in memory in 24 bit containers on 24 bit boundaries • 100b: Data is packed in memory in 32 bit containers on 32 bit boundaries All other bit combinations reserved
03:00	1h	**# Channels in Stream (NCS):** 2 channels in each frame

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ah	PARAM_PSB	Parameter Sizes and Bit Rates
0Bh	PARAM_SF	Stream Formats
0Fh	PARAM_SPS	Power Supported States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	0h	**Widget Type (TYPE):** Indicates this is an audio output widget
19:16		Sample Delay in Widget (DELAY):
15:13	011	**Channel Count Extension (CCE):** These three bits, combined with STRO, indicate that there are 8 channels supported.
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	0	**Connection List (CL):** Indicates no connection list
07	0	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	1	**Format Override (FO):** Indicates support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier support.
02	0	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ah: PSB - PCM Sizes and Bit Rates

Bits	Reset	Description
31:21	0	*Reserved*
20	1	**32-bit Support (B32):** Indicates 32-bit samples supported
19	1	**24-bit Support (B24):** Indicates 24-bit samples supported
18	0	**20-bit Support (B20):** Indicates 20-bit samples supported
17	1	**16-bit Support (B16):** Indicates 16-bit samples supported
16	0	**8-bit Support (B8):** Indicates 8-bit samples not supported
15:12	0	*Reserved*
11	0	**384 kHz Support (R12):** Indicates 384 kHz not supported
10	1	**192 kHz Support (R11):** Indicates 192 kHz supported
09	1	**176.4 kHz Support (R10):** Indicates 176.4 kHz supported
08	1	**96 kHz Support (R9):** Indicates 96 kHz supported
07	1	**88.2 kHz Support (R8):** Indicates 88.2 kHz supported
06	1	**48 kHz Support (R7):** Indicates 48 kHz supported
05	1	**44.1 kHz Support (R6):** Indicates 44.1 kHz supported
04	1	**32 kHz Support (R5):** Indicates 32 kHz supported
03	0	**22.05 kHz Support (R4):** Indicates 22.05 kHz not supported
02	0	**16 kHz Support (R3):** Indicates 16 kHz not supported
01	0	**11.025 kHz Support (R2):** Indicates 11.025 kHz not supported
00	0	**8 kHz Support (R1):** Indicates 8 kHz not supported

Parameter 0Bh: SF - Stream Formats

Bits	Reset	Description
31:03	0	*Reserved*
02	1	**AC3 Support (AC3):** Indicates AC3 stream format is supported
01	0	**Float32 Support (F32):** Indicates float32 stream format not supported
00	1	**PCM Support (PCM):** Indicates PCM format is supported.

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Default values will not be changed. This bit will report 0 in all cases.
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK

Bits	Reset	Description
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

706hF06h GETSET_CSID - GetSet Channel and Stream ID

Bits	Reset	Description
07:04	0h	**Stream ID (SID):** Link stream used by the converter for data output.
03:00	0h	**Lowest Channel Number (LCN):** Lowest channel used by the converter.

Digital Converter Verbs

F0Dh: GET_DC - Get Digital Converter

Bits	Reset	Description
31:24	0	Reserved
23	1	**Keep Alive (KA):** See SET_DC3.KA
22:20	0	Reserved
19:16	0h	**IEC Coding Type (ICT):** See SET_DC3.ICT
15	0	Reserved
14:08	00h	**Category Code (CC):** See SET_DC1.CC
07	0	**Level (LVL):** See SET_DC1.LVL
06	0	**Professional (PRO):** See SET_DC1.PRO
05	0	**Audio is not PCM (AUDIO):** See SET_DC1.AUDIO
04	0	**Copyright (COPY):** See SET_DC1.COPY
03	0	**Pre-emphasis (PRE):** See SET_DC1.PRE
02	0	**Validity Configuration (VCFG):** See SET_DC1.VCFG

Bits	Reset	Description
01	0	**Validity (V):** See SET_DC1.V
00	1	**Digital Enable (DIGEN):** See SET_DC1.DIGEN

70Dh: SET_DC1 - Set Digital Converter 1

Bits	Description
07	**Level (LVL):** S/PDIF IEC Generation Level.
06	**Professional (PRO):** When set, indicates professional use of channel.
05	**Audio is not PCM (AUDIO):** When set, data is non-PCM format.
04	**Copyright (COPY):** When set, copyright asserted.
03	**Pre-emphasis (PRE):** When set, enables filter pre-emphasis.
02	**Validity Configuration (VCFG):** Determines S/PDIF transmitter behavior when data is not being transmitted.
01	**Validity (V):** Affects the validity flag transmitted in each sub-frame, and enables S/PDIF transmitter to maintain connection during error or mute conditions.
00	**Digital Enable (DIGEN):** When set, enables digital content

70Eh: Digital Converter 2

Bits	Description
07	Reserved
06:00	**Category Code (CC):** S/PDIF IEC Category Code.

73Eh: Digital Converter 3

Bits	Description
07	Keep Alive
06:04	Reserved
03:00	IEC Coding Type

73Fh: Digital Converter 4

Bits	Description
07:00	Reserved

72DhF2Dh GETSET_CCC - GetSet Converter Channel Count

Bits	Reset	Description
07:04	0	Reserved
03:00	0000	Converter Channel Count 1 (0th order)

Pin Widget Verbs

Set Verb	Get Verb	Symbol	Verb Name

73Ch	F3Ch	SET_DPID / GET_DPID	Set/Get DisplayPort Stream ID

3h SET_AM - Set Amplifier Mute

Bits	Bits	Description
15	0	**Set Output Amp (SOA):**.
14	0	**Set Input Amp (SIA):**.
13	0	**Set Left Amp (SLA):**.
12	0	**Set Right Amp (SRA):**.
11:08	0h	**Index (IDX):**
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

B8h GET_AM - Get Amplifier Mute

Bits	Bits	Description
31:08	0	Reserved
07	1	**Mute (MUTE):** When set, amp is muted.
06:00	0	Reserved

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ch	PARAM_PC	Pin Capabilities
0Eh	PARAM_CLL	Connection List Length
12h	PARAM OAC	Output Amplifier Capabilities
15h	PARAM_DLL	Device List Length
0Fh	PARAM_SPS	Supported Power States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	4h	**Widget Type (TYPE):** Indicates this is a pin complex widget
19:16	0	**Sample Delay in Widget (DELAY):** No delay through the pin widget.
15:13	011	**Channel Count Extension (CCE):** This field, combined with STRO, indicate 8 channels supported.
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	1	**Connection List (CL):** Indicates a connection list
07	1	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	0	**Format Override (FO):** Indicates no support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier override support.
02	1	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ch: PC - Pin Capabilities

Bits	Reset	Description
31:28	0	*Reserved*
27	1	**High Bit Rate (HBR):** Indicates support for high bit-rate audio
26	0	*Reserved*
25	1	**Multi Stream Capable (MSC):** Indicates support for DisplayPort Multistream. Will be zero in vanilla mode.
24	1	**DisplayPort (DP):** Indicates support for DisplayPort
23:08	0	*Reserved*
07	1	**HDMI (HDMI):** Indicates support for HDMI
06:05	0	*Reserved*
04	1	**Output Capable (OC):** Pin is output capable
03	0	*Reserved*
02	1	**Presence Detect Capable (PDC):** Indicates capability for presence detection
01:00	0	*Reserved*

Parameter 0Eh: CLL - Connection List Length

Bits	Reset	Description
31:08	0	*Reserved*
07	0	**Long Form (LF):** Indicates connection list is short form
06:00	03h	**Length (LEN):** Indicates there is one item in the connection list.

Parameter 12h: OAC - Output Amplifier Capabilities

Bits	Reset	Description
31	1	**Mute Capable (MC):** Muting is capable on this pin
30:00	0	Reserved

Parameter 15h: DLL - Device List Length

Bits	Reset	Description
31:06	0	*Reserved*
05:00	00h	**Length (LEN):** Indicates no devices

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

701hF01h SETGET_CSC - SetGet Connection Select Control

Bits	Reset	Description
07:00	00h	**Connection Select Control (CSC):**

F02h GET_CLE - Get Connection List Entry

Bits	Reset	Description
31:08	0	Reserved
07:00	Varies	**Connection List Entry (CLE):** 02h for NodeID 05h, 03h for NodeID 06h, and 04h for NodeID 07h.

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Default values will not be changed. This bit will report 0 in all cases.
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

707hF07h SETGET_PWC - SetGet Pin Widget Control

Bits	Reset	Description
07	0	Reserved
06	1	**Out Enable (OE):** When set, the audio is enabled
05:02	0	Reserved
01:00	00	**Encoded Packet Type (EPT):**

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses are allowed
06	Reserved
05:00	**Tag (TAG):**

F09h GET_PS - Get Pin Sense

Determining SST / MST Mode

The audio codec will use multi-stream based indexing (MST mode) as described in the following sections if the following conditions are met, else it will use Non-MST mode.

Conditions for MST Mode
• In register **TRANS_DDI_FUNC_CTL**, the bit-field "TRANS DDI Mode Select" is set to "DP MST" **AND** • In verb GetSet iDisp Codec Vendor Verb (781h), the bit-field "Enable DP1.2 Features" (bit 1) is set to 1b.

Verb Parameters (Non-MST Mode)

For non-MST mode, the F09h verb response will automatically provide the status of the single pipe associated with the given pin node.

Nothing needs to be set in the data byte of the F09h Get Pin Sense verb.

Bits	Reset	Description
07:00	0	Reserved

Verb Parameters (MST Mode)

For MST mode, the F09h verb response will provide the status of the pipe selected in the Pipe Select bit-field, among the pipe(s) associated with the given pin node.

The data byte of the F09h Get Pin Sense verb should be programmed to select the desired pipe as shown below.

Bits	Reset	Description
07:06	0	Reserved
05:00	0	**Pipe Select:** Set to 000000b for pipe A, 000001b for pipe B, 000010b for pipe C, 000011b for pipe D

Verb Response (All Modes)

The verb response for the F09h Get Pin Sence verb command contains the following data regardless of which mode (Non-MST or MST) is used.

Bits	Reset	Description
31	0	**Presence Detect (PD):** When set presence is detected on this pin.
30	0	**ELD Value (ELDV):**

Bits	Reset	Description
29	0	**Inactive (INA):**
28:00	28:00	Reserved

71Ch SET_CD0 - Set Configuration Default Byte 0

Bits	Description
07:04	Default Association (DA):
03:00	Sequence (SEQ):

71Dh SET_CD1 - Set Configuration Default Byte 1

Bits	Description
07:04	Color (COL):
03:00	Miscellaneous (MISC):

71Eh SET_CD2 - Set Configuration Default Byte 2

Bits	Description
07:04	Default Device (DD):
03:00	Connection Type (CT):

71Fh SET_CD3 - Set Configuration Default Byte 3

Bits	Description
07:06	**Port Connectivity (PC):** External connectivity of the pin complex. • 00 = Connected to jack • 01 = No physical connection • 10 = Fixed function device (integrated speaker, mic, etc.) • 11 = Both a jack and internal connection

Bits	Description
05:00	**Location (LOC):** Bits 3:0 Bits 5:4 / 0h: N/A / 1h: Rear / 2h: Front / 3h: Left / 4h: Right / 5h: Top / 6h: Bottom / 7h: Special / 8h: Special / 9h: Special / Ah-Fh Reserved 00: External — Y Y Y Y Y Y Y Y Y 01: Internal — Y Y Y Y 10: Separate Chassis — Y Y Y Y Y Y Y 11: Other — Y Y Y Y Y

F1Ch GET_CD - Get Configuration Default

Bits	Description
31:30	**Port Connectivity (PC):** See SET_CD3.PC
29:24	**Location (L):** See SET_CD3.L
23:20	**Default Device (DD):** See Set_CD2.DD
19:16	**Connection Type (CT):** See Set_CD2.CT
15:12	**Color (COL):** See SET_CD1.COL
11:08	**Miscellaneous (MISC):** See SET_CD1.MISC
07:04	**Default Association (DA):** See SET_CD0.DA
03:00	**Sequence (SEQ):** See SET_CD0.SEQ

F2Eh HDMIDP Info Size

Bits	Reset	Description
31:08	0	Reset
07:00	Varies	**Size (SZ):** Indexes 0 - 3 return 1Eh, index 1000 returns 53h, others reserved.

F2Fh Get ELD Data

Parameter	Symbol	Register Name
07:0h	PARAM_INDX	ELD DATA Index

Parameter nn: ELD Data

Bits	Reset	Description
31:00	0	ELD Data

730hF30h SETGET_HII - SetGet HDMI Info Index

Bits	Reset	Description
07:05	000	**Infoframe Packet Index (IPI):** Value / Name / Value / Name 000 / Audio / 011 / GP3 001 / GP / 100 / GP4 010 / GP2 / Others / Reserved
04:00	00h	**Byte Offset Index Pointer (BOI):**

731hF31h SETGET_HID - SetGet HDMI Info Data

Bits	Reset	Description
07:00	00h	**Data (DATA):** Data at current index pointed to from SET_HII verb.

732hF32h SETGET_HITC - SetGet HDMI Info Transmit Control

Bits	Reset	Description
07:06	00	**InfoFrame Control Current Indexed Frame (IFCCIF):** • 00 = Disable Transmit • 01 = Reserved • 10 = Transmit Once • 11 = Best Effort
05:00	0	*Reserved*

733h SET_PC - Set Protection Control

Bits	Description
07:03	**Unsolicited Response Sub Tag (URST):** Subtag to use for unsolicited responsed.
02	Reserved

734hF34h SETGET_CCM - GetSet Converter Channel Map

Bits	Reset	Description
07:04	0h	Converter Channel (CC):
03:00	0h	Slot (SN):

735h SET_DS - Set Device Select

Bits	Reset	Description
07:06	0	*Reserved*
05:00	00h	**Device (D):** 000000, 000001, 000010, 000011 (based upon number of devices present)

F35h: GET_DS - Get Device Select

Bits	Description
31:12	**Reserved:** Set to 0
11:06	**SinK Device ID:** Sink Device ID in the multi stream topology of the DP hierarchy. Device attached to Pipe A will have ID of "000000", PipeB will have "000001", Pipe C will have "000010" and Pipe D will have "000011".
05:00	**Device (D):**Device Entry index currently set

F36h GET_DDLE - Get Display Device List Entry

Bits	Bits	Description
31:16	0	*Reserved*
15	0	*Reserved*
14	0	**IA of Entry 3**
13	0	**ELDV of Entry 3**
12	0	**PD of Entry 3**
11	0	*Reserved*
10	0	**IA of Entry 2**

Bits	Bits	Description
09	0	**ELDV of Entry 2**
08	0	**PD of Entry 2**
07	0	*Reserved*
06	0	**IA of Entry 1**
05	0	**ELDV of Entry 1**
04	0	**PD of Entry 1**
03	0	*Reserved*
02	0	**IA of Entry 0**
01	0	**ELDV of Entry 0**
00	0	**PD of Entry 0**

73ChF3Ch SETGET_DPID - SetGet DisplayPort Stream ID

Bits	Reset	Description
07:03	00h	**Tag (TAG):** Represents the SSID that will go in the lower 5 bits of the SSID
02:00	000	**Index (IDX):** Pointer to program multiple SSID

Intel Vendor Widget Verbs

Set Verb	Get Verb	Symbol	Verb Name
-	F00h	GET_PARAM	Get Parameters
-	F80h	GET_HDPS	Get HDMI/DP Status
781h	F81h	SET_HVV / GET_HVV	Set/Get iDisp Codec Vendor Verb
782h	-	SET_GTCT	Set GTC Trigger
-	F83h	GET_CWC	Get Captured Wall Clock
	F84h	GET_CGTC	Get Captured GTC Value
	F85h	GET_GOF	Get GTC Offset Value
785h	-	SET_GOF0	Set GTC Offset Value Byte 0
786h	-	SET_GOF1	Set GTC Offset Value Byte 1
787h	-	SET_GOF2	Set GTC Offset Value Byte 2

Set Verb	Get Verb	Symbol	Verb Name
788h	-	SET_GOF3	Set GTC Offset Value Byte 3
789h	F89h	SET_GDI / GET_GDI	Set/Get GTC Offset Device Index

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	Fh	**Widget Type (TYPE):** Indicates this is a vendor defined widget
19:00	0	Reserved

71Eh SET_GET_GFXMAILBOX - Set Get GFX MAILBOX Byte 2

71Eh: SET GFX MAILBOXM

Bits	Default	Description
07:00	00	Contents to be defined by GFX driver and audio driver

F1Eh: GET GFX MAILBOX

Bits	Default	Description
31:24	00h	Other values of 71F, verbs
23:16	00h	Contents to be defined by GFX driver and audio driver
15:00	0000h	Other values of 71D, 71C verb

728h SET CLOCK OFF - Set Clock Off Command

Bits	Description
07:00	Data is Irrelevant

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses from GFX MAIL BOX register writes are allowed.
06	Reserved
05:00	**Tag (TAG):** Tag for GFX Mail box register unsol responses.

781hF81h GETSET_VV - GetSet iDisp Codec Vendor Verb

Bits	Default	Description
07:04	0	**Port Select:** This filed is programmed to select the port to be exposed to the inbox driver in the vanilla mode. Will not reset on double function group reset. 0000 -> DDI A 0001 -> DDI B 0010 -> DDI C 0011 -> USBC1 0100 -> USBC2 0101 -> USBC3 0110 -> USBC4 0111 -> USBC5 1000 -> USBC6
03:02	0	**Reserved**
01	0	**Enable DP1.2 Features (EDP12):** When set, DP1.2 features are enabled. Will not reset on double function group reset.
00	0	**Enable all Pins and all Converter Widget (E3P):** When set, all the pins and converter widgets are enabled and can respond to HD Audio Verbs. When cleared, only one Pin and one converter widgets are exposed. Pin selection is done programming bits 7:5. Will not reset on double function group reset.

782h SET_GTCT - Set GTC Trigger

Bits	Bits	Description
07:00	0	**Any data:** The value of this field is irrelevant. The access of the SET causes a capture to occur.

F83h GET_CGTC - Get Captured GTC Value

Bits	Bits	Description
07	0	**GTC Value:** 32-bit GTC value captured on the SET_GTCT verb

F84h GET_CWC - Get Captured Wall Clock Value

Bits	Bits	Description
31:00	0	**Wall Clock Value:** 32-bit wall clock value captured on the SET_GTCT verb

F85h GET GOF - Get GTC Offset Value

Bits	Reset	Description
31:00	0h	**Value (VAL):** Reports the GTC Offset Value.

785h SET GOF0 - Set GTC Offset Value Byte 0

Bits	Description
07:00	GTC Offset Value Bits [7:0]

786h SET GOF1 - Set GTC Offset Value Byte 1

Bits	Description
07:00	GTC Offset Value Bits [15:8]

787h SET GOF2 - Set GTC Offset Value Byte 2

Bits	Description
07:00	GTC Offset Value Bits [23:16]

788h SET GOF3 - GTC Offset Value Byte 3

Bits	Description
07:00	GTC Offset Value Bits [31:24]

789hF89h SETGET_GDI - SetGet GTC Device Index

Bits	Reset	Description
07:06	0	*Reserved*
05:00	00h	**Device (D):** 000001, 000010 (based upon number of devices present) This is the pipe based. 000000 i s pipeA and so on and so forth.

Intel Wireless Widget Verbs

Set Verb	Get Verb	Symbol	Verb Name
3h	-	SET_AM	Set Amplifier Mute
-	Bh	GET_AM	Get Amplifier Mute
-	F00h	-	Get Parameters
701h	F01h	SET_CSC / GET_CSC	Set/Get Connection Select Control
-	F02h	-	Get Connection List Entry
705h	F05h	SET_PS / GET_PS	Set/Get Power State
707h	F07h	SET_PWC / GET_PWC	Set/Get Pin Widget Control
708h	F08h	SET_UE / GET_UE	Set/Get Unsolicited Response Enable
-	F09h	-	Get Pin Sense
71Ch	-	SET_CD0	Set Configuration Default Byte 0
71Dh	-	SET_CD1	Set Configuration Default Byte 1
71Eh	-	SET_CD2	Set Configuration Default Byte 2
71Fh	-	SET_CD3	Set Configuration Default Byte 3
-	F1Ch	GET_CD	Get Configuration Default
-	F2Eh	GET_HDIS	Get HDMI/DP Info Size
733h	F33h	SET_PC / GET_PC	Set/Get Protection Control
734h	F34h	SET_CCM / GET_CCM	Set/Get Converter Channel Map
73Ch	F3Ch	SET_STRID / GET_STRID	Set/Get Widi Stream ID
740h-743h	F40h-F43h	SET / GET_PTSOFFSET	Set/Get PTS Offset Byte 0, 1, 2, 3
750h-753h	F50h-F53h	SET / GET Widi Buf LowBase Addr	Set/Get Widi Lower base address Byte 0, 1, 2, 3
754h-757h	F54h-F57h	SET / GET Widi Buf Upper Base Addr	Set/Get Widi Upper base address Byte 0, 1, 2, 3
760h-763h	F60h-F63h	SET / GET Widi Buf size	Set/Get Widi Buf Size Byte 0, 1, 2, 3
764h	F64h	SET / GET WDE TFD Size	Set/Get WDE TFD Size
770h	F70h	SET/GET Widi PID	Set/Get Widi PID
780h-783h	F80h-F83h	SET/GET WDE/WFA Header	Set/Get WDE/WFA Header
784h	F84h	SET/GET WDE Program Number	Set/Get WDE Program number

Set Verb	Get Verb	Symbol	Verb Name
785h-786h	F85h-F86h	SET/GET WDE STD Bit Rate	Set/Get WDE STD bit rate
787h	F87h	SET/GET WDE PKT PER FRM	Set/Get Packets per frame
788h	F88h	SET/GET Wireless Widget Mode	Set/Get Wireless Widget Mode (Wigig, Widi, WFA)

3h SET_AM - Set Amplifier Mute

Bits	Bits	Description
15	0	**Set Output Amp (SOA):**.
14	0	**Set Input Amp (SIA):**.
13	0	**Set Left Amp (SLA):**.
12	0	**Set Right Amp (SRA):**.
11:08	0h	**Index (IDX):**
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

B8h GET_AM - Get Amplifier Mute

Bits	Bits	Description
31:08	0	*Reserved*
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ch	PARAM_PC	Pin Capabilities
0Eh	PARAM_CLL	Connection List Length
12h	PARAM OAC	Output Amplifier Capabilities
0Fh	PARAM_PS	Supported Power States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	4h	**Widget Type (TYPE):** Indicates this is a pin complex widget
19:16	0	**Sample Delay in Widget (DELAY):** No delay through the pin widget.
15:13	011	**Channel Count Extension (CCE):** This field, combined with STRO, indicate 8 channels supported.
12	0	**Content Protection Capable (CPC):** Indicates pin capable of content protection.
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	1	**Connection List (CL):** Indicates a connection list
07	1	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	0	**Format Override (FO):** Indicates no support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier override support.
02	1	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ch: PC - Pin Capabilities

Bits	Reset	Description
31:28	0	*Reserved*
27	1	**High Bit Rate (HBR):** Indicates support for high bit-rate audio
26	0	*Reserved*
25	0	*MST capable (DP1.2)*
24	1	**DisplayPort (DP):** Indicates support for DisplayPort
23:08	0	*Reserved*
07	1	**HDMI (HDMI):** Indicates support for HDMI
06:05	0	*Reserved*
04	1	**Output Capable (OC):** Pin is output capable
03	0	*Reserved*
02	1	**Presence Detect Capable (PDC):** Indicates capability for presence detection
01:00	0	*Reserved*

Parameter 0Eh: CLL - Connection List Length

Bits	Reset	Description
31:08	0	*Reserved*
07	0	**Long Form (LF):** Indicates connection list is short form
06:00	03h	**Length (LEN):** Indicates there is one item in the connection list.

Parameter 12h: OAC - Output Amplifier Capabilities

Bits	Reset	Description
31	1	**Mute Capable (MC):** Muting is capable on this pin
30:00	0	Reserved

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

701hF01h SETGET_CSC - SetGet Connection Select Control

Bits	Reset	Description
07:00	00h	**Connection Select Control (CSC):**

F02h GET_CLE - Get Connection List Entry

Bits	Reset	Description
31:24	0	Reserved
23:16	100	**Connection List Entry (CLE):** Hardwired to Converter ID 4
15:08	011	**Connection List Entry (CLE)**: Hardwired to Converter ID 3
07:00	010	**Connection List Entry (CLE)**: Hardwired to Converter ID 2

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Default values will not be changed. This bit will report 0 in all cases.
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

707hF07h SETGET_PWC - SetGet Pin Widget Control

Bits	Reset	Description
07	0	Reserved
06	1	**Out Enable (OE):** When set, the audio is enabled
05:02	0	Reserved
01:00	00	**Encoded Packet Type (EPT):**

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses are allowed
06	Reserved
05:00	**Tag (TAG):**

F09h GET_PS - Get Pin Sense

Bits	Reset	Description
31	0	**Presence Detect (PD):** When set presence is detected on this pin.
30	0	**ELD Value (ELDV):**
29	0	**Inactive (INA):**
28:00	28:00	Reserved

71Ch SET_CD0 - Set Configuration Default Byte 0

Bits	Description
07:04	Default Association (DA):
03:00	Sequence (SEQ):

71Dh SET_CD1 - Set Configuration Default Byte 1

Bits	Description
07:04	Color (COL):
03:00	Miscellaneous (MISC):

71Eh SET_CD2 - Set Configuration Default Byte 2

Bits	Description
07:04	Default Device (DD):
03:00	Connection Type (CT):

71Fh SET_CD3 - Set Configuration Default Byte 3

Bits	Description
07:06	**Port Connectivity (PC):** External connectivity of the pin complex. • 00 = Connected to jack • 01 = No physical connection • 10 = Fixed function device (integrated speaker, mic, etc.) • 11 = Both a jack and internal connection
05:00	**Location (LOC):**

Bits	Description

	Bits 3:0										
Bits 5:4	0h: N/A	1h: Rear	2h: Front	3h: Left	4h: Right	5h: Top	6h: Bottom	7h: Special	8h: Special	9h: Special	Ah-Fh Reserved
00: External	Y	Y	Y	Y	Y	Y	Y	Y	Y		
01: Internal	Y							Y	Y	Y	
10: Separate Chassis	Y	Y	Y	Y	Y	Y	Y				
11: Other	Y						Y	Y	Y		

F1Ch GET_CD - Get Configuration Default

Bits	Description
31:30	**Port Connectivity (PC):** See SET_CD3.PC
29:24	**Location (L):** See SET_CD3.L
23:20	**Default Device (DD):** See Set_CD2.DD
19:16	**Connection Type (CT):** See Set_CD2.CT
15:12	**Color (COL):** See SET_CD1.COL
11:08	**Miscellaneous (MISC):** See SET_CD1.MISC
07:04	**Default Association (DA):** See SET_CD0.DA
03:00	**Sequence (SEQ):** See SET_CD0.SEQ

F2Eh WIDI ELD Size

Bits	Reset	Description
31:08	0	Reset
07:00	Varies	**Size (SZ)**Reserved as we do not have Info frame support for WIdi widget. Will return the value 53h as the response.

F2Fh Get ELD Data

Parameter	Symbol	Register Name
07:0h	PARAM_INDX	ELD DATA Index

Parameter nn: ELD Data

Bits	Reset	Description
31:00	0	ELD Data

733h SET_PC - Set Protection Control

Bits	Description
07:03	**Unsolicited Response Sub Tag (URST):** Subtag to use for unsolicited responsed.
02	Reserved
01:00	**Content Protection Requested (CPR):** • 00 = Don't Care • 01 = Reserved • 10 = protection OFF • 11 = Protection ON

734hF34h SETGET_CCM - GetSet Converter Channel Map

Bits	Reset	Description
07:04	0h	Converter Channel (CC):
03:00	0h	Slot (SN):

73ChF3Ch SETGET_STRID - SetGet WIDI Stream ID

Bits	Reset	Description
07:00	00h	**WDSTRMID (WDSTRMID):** Represents the SSID that will go in the TS HEADER of PES and DATA packets

740hF40h SETGET PTS Offset Byte0

Bits	Reset	Description
07:00	00h	**PTS B0(PTSB0):** Bits 7:0 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

741hF41h SETGET PTS Offset Byte1

Bits	Reset	Description
07:00	00h	**PTS B1(PTSB1):** Bits 15:8 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

742hF42h SETGET PTS Offset Byte2

Bits	Reset	Description
07:00	00h	**PTS B2(PTSB2):** Bits 23:16 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

743hF43h SETGET PTS Offset Byte3

Bits	Reset	Description
07:00	00h	**PTS B3(PTSB3):** Bits 31:24 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

750hF50h SETGET Widi Buffer Base Address Byte0

Bits	Reset	Description
07:00	00h	**BLADDR Byte0(BLADDR0):** Bits 7: 0 of the 32 bits of the lower base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

751hF51h SETGET Widi Buffer Base Address Byte1

Bits	Reset	Description
07:00	00h	**BLADDR Byte1(BLADDR1):** Bits 15: 8 of the 32 bits of the lower base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

752hF52h SETGET Widi Buffer Base Address Byte2

Bits	Reset	Description
07:00	00h	**BLADDR Byte2(BLADDR2):** Bits 23:16 of the 32 bits of the lower base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

753hF53h SETGET Widi Buffer Base Address Byte3

Bits	Reset	Description
07:00	00h	**BLADDR Byte3(BLADDR3):** Bits 31:24 of the 32 bits of the lower base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

754hF54h SETGET Widi Buffer Upper Base Address Byte0

Bits	Reset	Description
07:00	00h	**BUADDR Byte0(BUADDR0):** Bits 7: 0 of the 32 bits of the upper base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

755hF55h SETGET Widi Buffer Upper Base Address Byte1

Bits	Reset	Description
07:00	00h	**BUADDR Byte1(BUADDR1):** Bits 15:8 of the 32 bits of the upper base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

756hF56h SETGET Widi Buffer Upper Base Address Byte2

Bits	Reset	Description
07:00	00h	**BUADDR Byte2(BUADDR2):** Bits 23:16 of the 32 bits of the Upper base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

757hF57h SETGET Widi Buffer Upper Base Address Byte3

Bits	Reset	Description
07:00	00h	**BUADDR Byte3(BUADDR3):** Bits 31:24 of the 32 bits of the Upper base address of the widi circular buffer. This is a physical address of the Stolen memory. Address is cacheline aligned.

760hF60h SETGET Widi Buffer Size Byte0

Bits	Reset	Description
07:00	00h	**BSIZE Byte0(BSIZE0):** Bits 7: 0 of the 32 bits of the size of the widi circular buffer. Size is in number of cachelines. It should be multiple of 3 Cachelines. Total buffer size cannot exceed more than 4MBytes For Wigig mode this represents the number of TFDs in the buffer.

761hF61h SETGET Widi Buffer Size Byte1

Bits	Reset	Description
07:00	00h	**BSIZE Byte1(BSIZE1):** Bits 15:8 of the 32 bits of the size of the widi circular buffer. Size is in number of cachelines. It should be multiple of 3 Cachelines. Total buffer size cannot exceed more than 4MBytes. For Wigig mode this represents the number of TFDs in the buffer.

762hF62h SETGET Widi Buffer Size Byte2

Bits	Reset	Description
07:00	00h	**BSIZE Byte2(BSIZE2):** Bits 23:16 of the 32 bits of the size of the widi circular buffer. Size is in number of cachelines. It should be multiple of 3 Cachelines. Total buffer size cannot exceed more than 4MBytes For Wigig mode this represents the number of TFDs in the buffer.

763hF63h SETGET Widi Buffer Size Byte3

Bits	Reset	Description
07:00	00h	**BSIZE Byte3(BSIZE3):** Bits 31:24 of the 32 bits of the size of the widi circular buffer. Size is in number of cachelines. It should be multiple of 3 Cachelines. Total buffer size cannot exceed more than 4MBytes. For Wigig mode this represents the number of TFDs in the buffer.

764hF64h SETGET WDE TFD size

764h: SET WDE TFD Size

Bits	Default	Description
07:04	00000	Reserved
03	0	This is an enable. If set, the tfd size is value is taken from here. Otherwise the tfd size is taken from WD_CNTRL register of MMIO.
02:00	000	This is TFD size. Valid only for WiGig mode. The total circular buffer should be a multiple of this number. 000b 512B [Default] default size of TFD is 512B 001b 1024B TFD Size is 1024B 010b 2048B TFD Size is 2048B 011b 4096B TFD Size is 4096B 100b 8192B TFD Size is 8192B Others: Reserved

North Display Engine Registers

This chapter contains the register descriptions for the display engine portion of a family of graphics devices.

These registers vary by devices within the family of devices, so special attention needs to be paid to which devices use which registers and register fields.

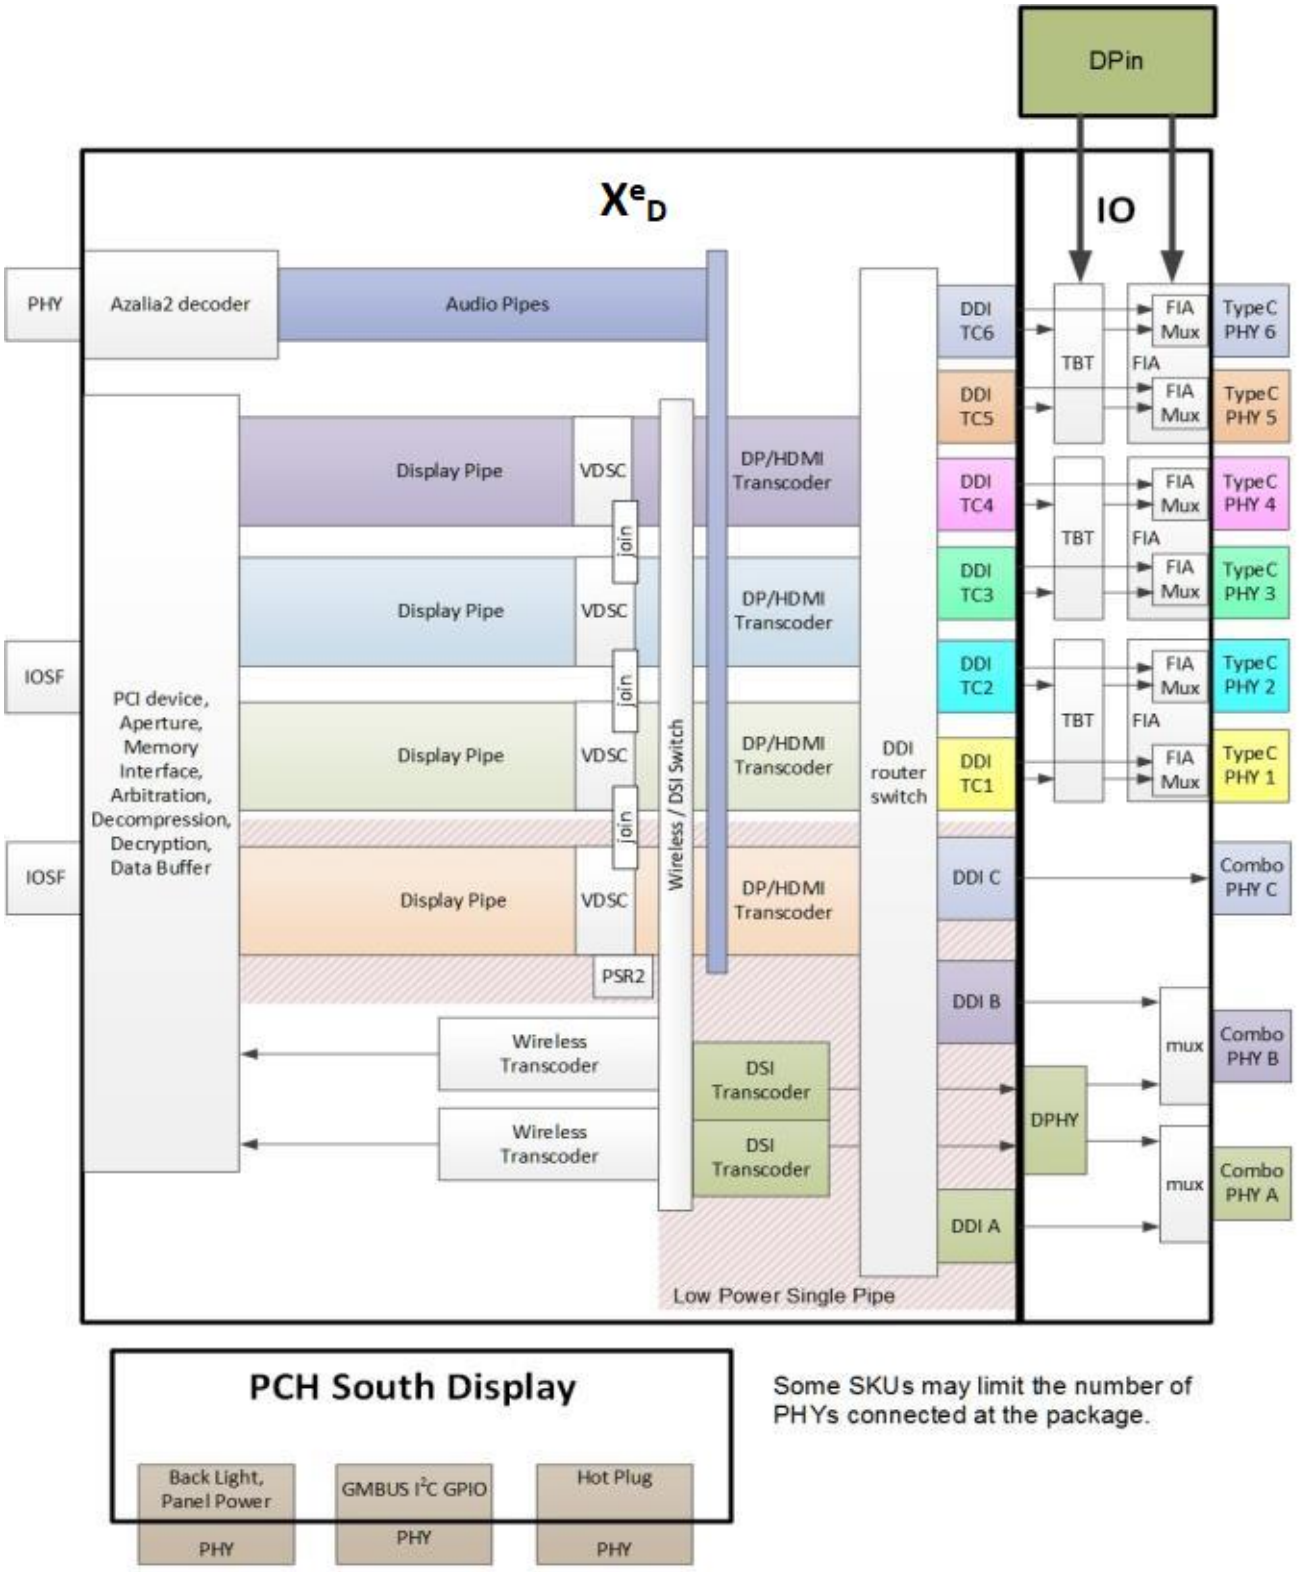
Different devices within the family may add, modify, or delete registers or register fields relative to another device in the same family based on the supported functions of that device.

Xe_D Overview

Genesis

This project uses Xe_D.

Block Diagram



The front end of the display contains the pipes. The pipes connect to the transcoders. The transcoders, except for wireless, connect to the DDIs to drive the IO/PHY. Wireless writes back to memory. DPin allows external graphics DisplayPort output to be routed to typeC and thunderbolt.

General Capabilities

Four simultaneous displays (pipes A, B, C, D)

- 7 planes and 1 cursor per pipe
- Audio streams per pipe to go to external ports
- HDR support for 3 planes per pipe
- VESA DSC compression support for all pipes
- Post-DSC joining to connect 2 adjacent pipes for resolutions that require more bandwidth than one pipe can support
- Pipe A optimized for low power

External display connections

- 2 wireless
- 3 combo ports (DisplayPort, HDMI, or eDP)
- 6 USB Type C ports (DisplayPort alternate mode, DisplayPort over thunderbolt, native DisplayPort on legacy connector, native HDMI on legacy connector)
- Hotplug for type C
- AUX channels for DisplayPorts
- Multi-stream support for DisplayPorts
- Genlock support on all combo ports at display IP level but not at SoC level. Feature cannot be used.

Embedded/local display connections

- 3 combo ports that can support eDP, DSI, and external ports, but only one low power optimized port at a time
- 1 x8 MIPI DSI or 2 x4 MIPI DSI (shared pins on DDIA and DDIB)
- Combo IO shares pins between DSI0 and DDIA and between DSI1 and DDIB
- AUX channel for eDP
- PSR1, PSR2, and MSO (multi-segmented operation, chip on glass) for eDP

PCH

- Backlight modulation PWM, panel power sequencing, GMBUS I2C, non-typeC hot plug detection

Port Configurations

Port Type	# of ports[1]	Protocol	Maximum Speed	Maximum Resolution[2]
Combo	1 port 8 lanes or 2 ports 4 lanes	MIPI DSI 1.3	2.5 Gbps	5k 60Hz compressed
"	3[3]	eDP 1.4b	HBR3 8.1 Gbps	5k 60Hz 24bpp
"	3	DP 1.4a	HBR2 5.4 Gbps	4k 60Hz 24bpp
"	3	HDMI 1.4	2.97 Gbps	4k 30Hz 24bpp
"	3	HDMI 2.0b	5.94 Gbps	4k 60Hz 24bpp
USB Type-C[4]	6	DP 1.4a	HBR3 8.1 Gbps	8k 60Hz compressed, 5k 120Hz compressed
"	6	HDMI 1.4	2.97 Gbps	4k 30Hz 24bpp
"	6	HDMI 2.0b	5.94 Gbps	4k 60Hz 24bpp
Capture	2	N/A	N/A	Single display 4k 60Hz 30bpp Dual display 2560x1600 60Hz 30bpp

[1] Many SKUs will limit the number of ports connected at the package. Only one power optimized port for eDP.

[2] Resolution restrictions

- Resolutions supported, but not a guarantee of user experience.
- Thermal constraints may apply.
- Multi-display resolution support limited.
- Subject to memory bandwidth availability. Software configuration constrained to fit available bandwidth.
- These are single cable panel (non-tiled panel) resolutions. Panels with two cables may support higher resolution by using two ports.
- Higher bits per color may be possible at lower resolutions.
- Some resolutions require compression (VDSC). VDSC input and output bits per color are limited.
- Supports other resolutions and bits per color that fit the same bandwidth and size constraints.
- Software configuration constrained to fit available bandwidth with current memory configuration.

[3] Only one power optimized port for eDP.

[4] USB type-C PHY can support DP alternate mode, DP tunneled over thunderbolt, DP with legacy connector, or HDMI with legacy connector.

Multiple Display Resolution Support

This table gives the required resolution support. Actual results may have higher resolution, depending on exact details of the configuration, such as the number of planes enabled and pixel formats.

Number of simultaneous displays	Maximum Common Resolution
1	8k 60Hz HDR or 5k 120Hz HDR
2	5k 60Hz SDR or 4k 60Hz HDR
3 or 4	4k 60Hz HDR

All subject to resolution restrictions noted under the Port Configurations table.

HDR (High Dynamic Range) increases memory bandwidth compared to standard dynamic range (SDR).

Software does not have explicit restrictions for multiple display cases, just constraints to fit available bandwidth with current memory configuration.

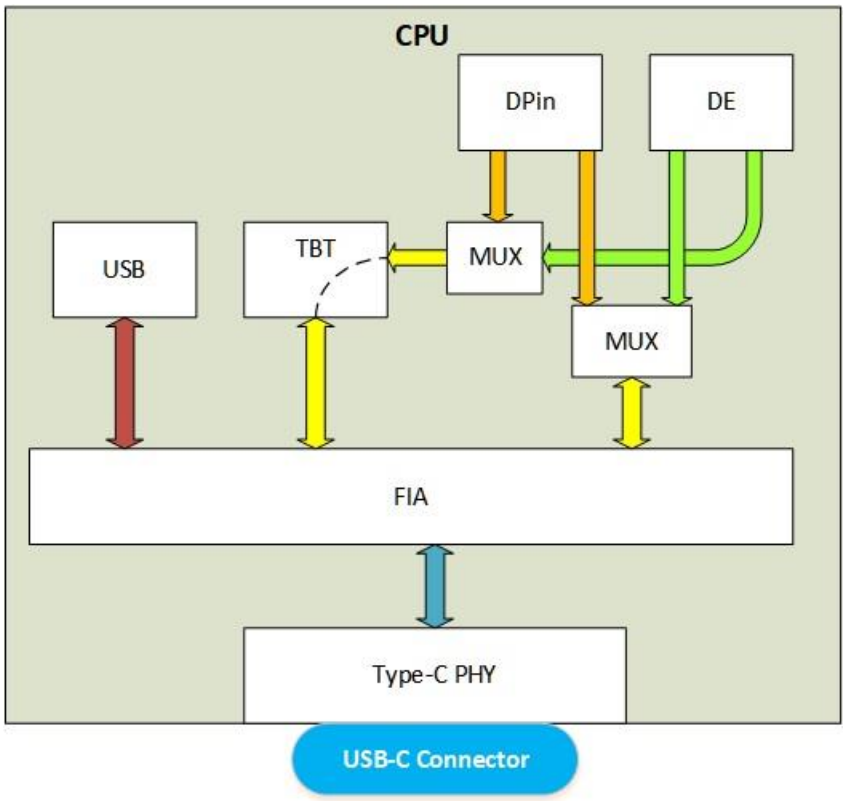
See the Resolution Support page for detailed restrictions and calculations.

Port Availability

Port	Usage	Capability	Alternate Names
DDI A	Combo port A	eDP, DP, HDMI, MIPI DSI 0	DDIA, Port A, Combo Port A, MIPIA, MIPI0
DDI B	Combo port B	eDP, DP, HDMI, MIPI DSI 1	DDIB, Port B, Combo Port B, MIPIB, MIPI1
DDI C	Combo port C	eDP, DP, HDMI	DDIC, Port C, Combo Port C
TC 1	Type C port 1	DP alternate mode, DP over Thunderbolt, native/legacy DP, native/legacy HDMI	Type C Port 1, TC1, USBC1
TC 2	Type C port 2	DP alternate mode, DP over Thunderbolt, native/legacy DP, native/legacy HDMI	Type C Port 2, TC2, USBC2
TC 3	Type C port 3	DP alternate mode, DP over Thunderbolt, native/legacy DP, native/legacy HDMI	Type C Port 3, TC3, USBC3
TC 4	Type C port 4	DP alternate mode, DP over Thunderbolt, native/legacy DP, native/legacy HDMI	Type C Port 4, TC4, USBC4
TC 5	Type C port 5	DP alternate mode, DP over Thunderbolt, native/legacy DP, native/legacy HDMI	Type C Port 5, TC5, USBC5
TC 6	Type C port 6	DP alternate mode, DP over Thunderbolt, native/legacy DP, native/legacy HDMI	Type C Port 6, TC6, USBC6

Some SKUs will limit which ports are connected in the die and package. Software should rely on hotplug to determine which ports are actually available.

USB TypeC



The USB type C ports are integrated into the CPU. Each type C port is shared between USB, thunderbolt (TBT), DPin, and display engine.

FIA selects between the controllers and handles cable orientation swapping. Multiple controllers can share the connector simultaneously, but with reduced number of lanes for each.

Display engine has 4 output types for type C

- DisplayPort alternate mode: Display engine sends DisplayPort data to FIA to be muxed to the correct PHY lanes. DP can use 2 or 4 of the data lanes, depending on whether the connector is being shared with another controller.
- DisplayPort over thunderbolt: Display engine sends DisplayPort data to the thunderbolt controller, which combines up to 2 DisplayPort streams with other data streams and sends it to FIA to be muxed to the correct PHY lanes.
- Native HDMI: This is used for a legacy HDMI connector on a type C port. Display engine sends data to FIA to be passed through to the correct PHY lanes. There is no muxing with other controllers.
- Native DisplayPort: This is used for a legacy DisplayPort connector on a type C port. Display engine sends data to FIA to be passed through to the correct PHY lanes. There is no muxing with other controllers.

The type C sub-system IOM and power delivery controller determine the ownership of the type C connector. They interpret type C hotplug events and decide whether the hotplug should be routed to display engine or to one of the other controllers, and which lanes are available for DP alternate mode.

If the hotplug is directed to display engine it can take 3 paths

- Legacy hotplug interrupt: This interrupt comes through the south display hotplug detection and interrupt. This is used for the native HDMI or DP case with a legacy connector on a type C port.
- Thunderbolt hotplug interrupt: This interrupt comes through the north display thunderbolt hotplug control and interrupt. This is used for DP over thunderbolt.
- DP alternate hotplug interrupt: This interrupt comes through the north display typeC hotplug control and interrupt. This is used for DP alternate mode.

Depending on the type of interrupt, software needs to configure the display output to go to the correct destination.

Power Wells

Display engine functions are spread across several different power gated (PG) wells that can be shut down to optimize power for different configurations.

Hardware can dynamically control some PGs for display power states. That is enabled through the DC State programming.

Refer to Sequences for Power Wells for more details on the functions in each power well and the sequences for enabling and disabling power.

Interface
Dither
To Transcoders

The display pipes contain the planes, blending, color measurement and adjustment, scaling, and dithering.

FBC and LDPST are supported only on pipe A.

3D LUT is supported only on pipes A and B.

The planes read data from memory, format it into pixels, and can apply color correction and scaling.

Each display pipe has 7 planes and a cursor.

The plane blending combines the output from all the planes following a fixed Z-order. Plane 1 is the bottom most plane and higher numbered planes stack on top of it. Cursor goes ontop of all the planes.

Planes 1-3 support HDR. Planes 4-7 support SDR. Plane details are in the Universal Plane and Plane Capability and Interoperability sections.

The background color that is seen under the bottom most plane is programmable.

The blended pixels pass through several color correction functions and then output to the transcoders.

The pipes each have two pipe scalers. Each pipe scaler can be assigned to scale a plane or scale the blended output.

Transcoders

The display transcoders contain the timing generators, port encoders, DisplayPort transport control, Audio/Video mixers, Video Data Island Packet mixers, and Panel Self Refresh controllers.

Except for the WD (Wireless Display, Capture) transcoders, the transcoders convert pixel data to the appropriate format for the port, mix in data islands and audio, and output the data to the DDIs.

The WD transcoders convert pixel data to the appropriate format, then write it to system memory.

Transcoder A-D can support DP or HDMI, with audio.

Transcoders DSI* only support MIPI DSI.

Only transcoder A supports PSR2.

Only transcoder A supports eDP CoG.

The transcoders, except for wireless transcoders, can make use of VDSC compression.

Audio

The Azalia2 interface provides data to the audio codec.

The audio codec connects to the Audio/Video mixers in the transcoders.

The audio codec can also write data back to system memory for wireless audio.

DDIs (Digital Display Interfaces)

The DDIs contain port logic to interface to the DDI physical (PHY) layer.

The DDIs going to the combo PHY support lane reversal where the internal lane to package lane mapping is swapped. The DDIs going to the type C PHY rely on FIA to do lane reversal.

A Combo PHY capable of supporting DDI or MIPI DSI is attached to DDI A and DDI B. It can select between MIPI DSI output or DDI output. Dynamic switching between the two configurations is not supported.

Some of the DDI GPIO and HPD pins are reused for MIPI DSI panel controls.

DDI Lane Mapping:

Package Pin	DisplayPort Non-Reversed	DisplayPort Reversed	HDMI/DVI Non-Reversed	HDMI/DVI Reversed
DDI data 3	Main Link Lane 3	Main Link Lane 0	TMDS Clock	TMDS Data2
DDI data 2	Main Link Lane 2	Main Link Lane 1	TMDS Data0	TMDS Data1
DDI data 1	Main Link Lane 1	Main Link Lane 2	TMDS Data1	TMDS Data0
DDI data 0	Main Link Lane 0	Main Link Lane 3	TMDS Data2	TMDS Clock

MIPI DSI Lane Mapping:

Package Pin	MIPI DSI Connection
DDIA data 3	DSI 0 Data 3
DDIA data 2	DSI 0 Clock
DDIA data 1	DSI 0 Data 2
DDIA data 0	DSI 0 Data 1
DDIA AUX	DSI 0 Data 0
DDIB data 3	DSI 1 Data 3
DDIB data 2	DSI 1 Clock
DDIB data 1	DSI 1 Data 2
DDIB data 0	DSI 1 Data 1
DDIB AUX	DSI 1 Data 0

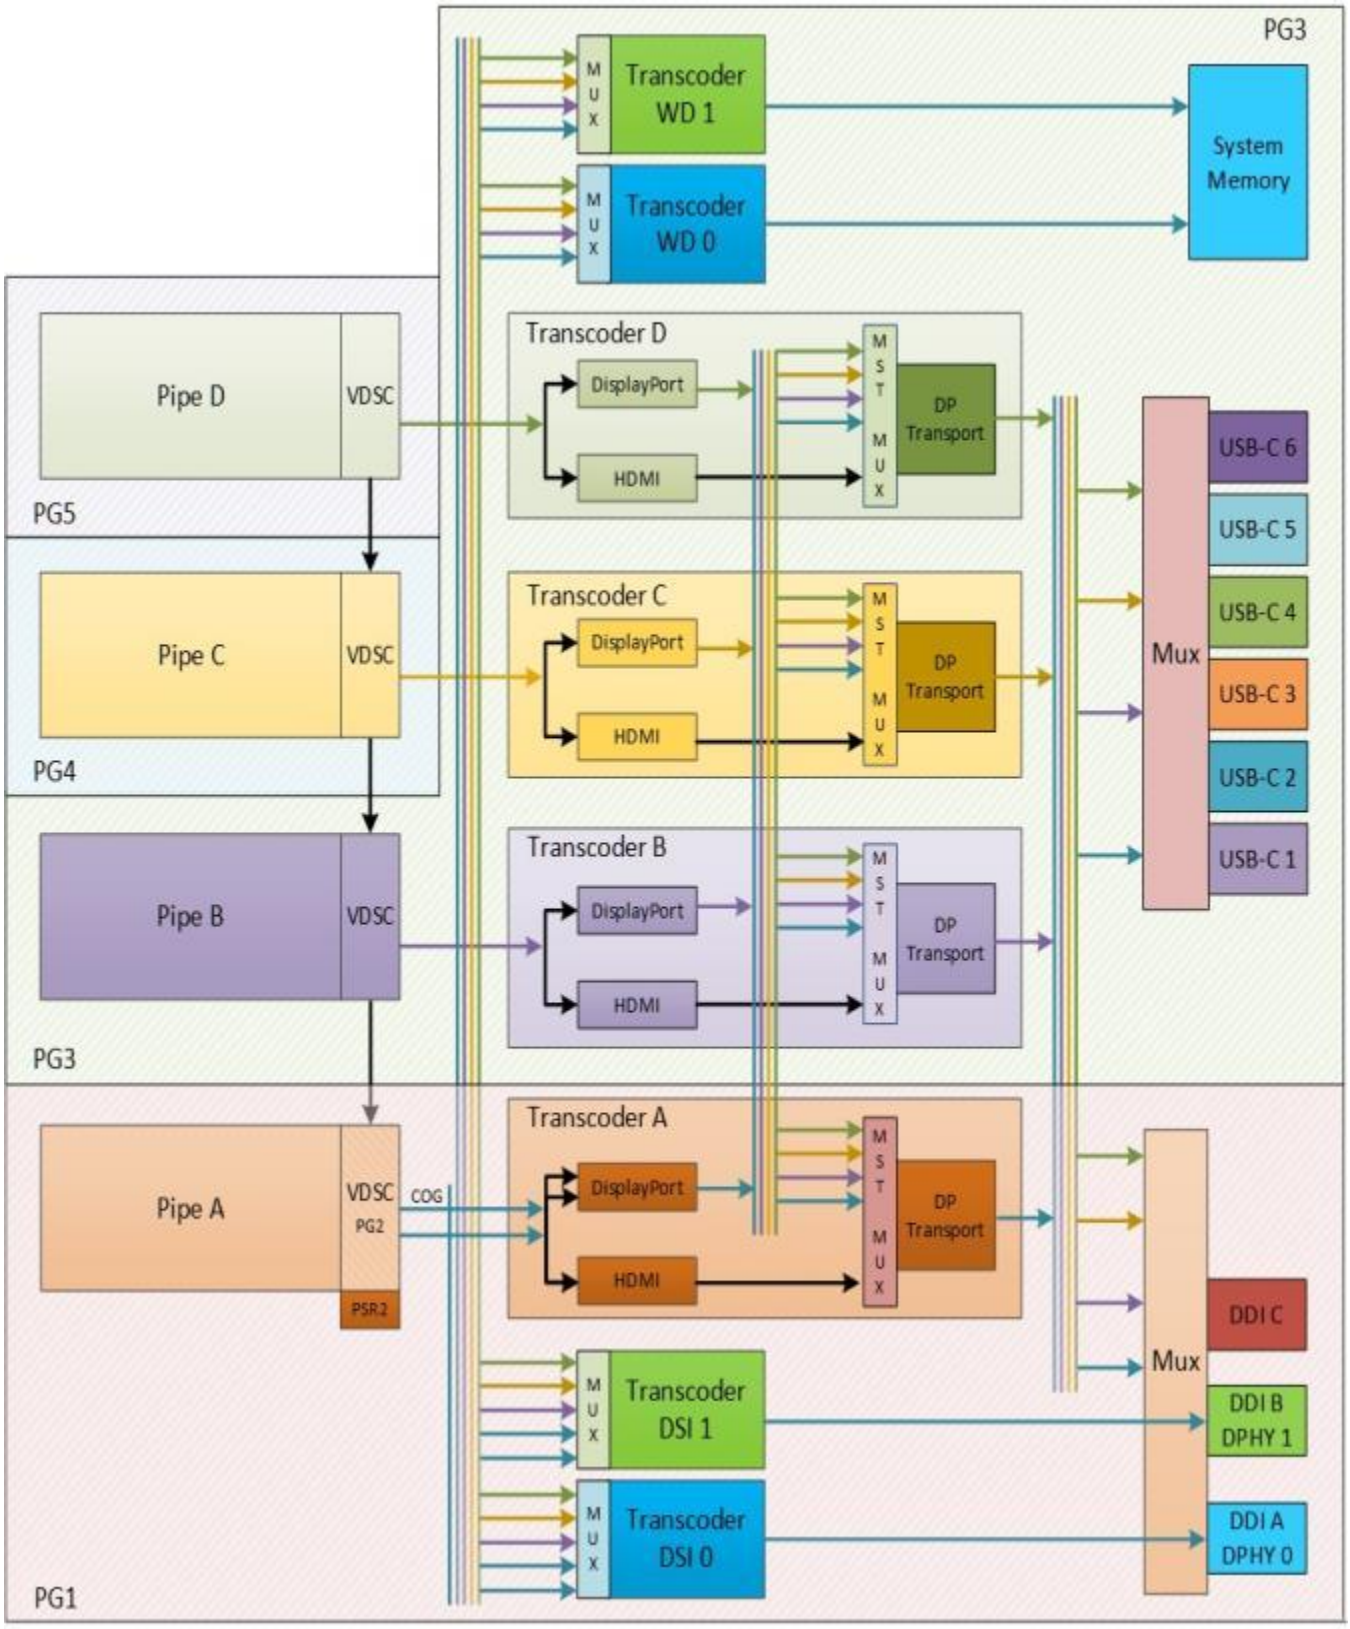
DDI and MIPI DSI Pin Sharing:

DDI pins	Non-MIPI DSI board	MIPI DSI 8 lane board	MIPI DSI 4 lane board
DDIA data and AUX	DDIA embedded DisplayPort	MIPI DSI 0	MIPI DSI 0
DDIB data and AUX	DDIB DisplayPort, HDMI, or DVI	MIPI DSI 1	DDIB DisplayPort, HDMI, or DVI
DDIA HPD	EDP HPD	MIPI panel RESET	MIPI panel RESET
DDIA DDC clock	Unused	MIPI panel AVEE	MIPI panel AVEE
DDIA DDC data	Unused	MIPI panel VIO	MIPI panel VIO

MIPI DSI Panel Pins Mapping to Display GPIO Pins

MIPI Panel Pin	GPIO Pin	Controls
RESET	DDSP_HPD_A	South display SHOTPLUG_CTL_DDI DDIA HPD Output Data
AVEE	DDPA_CTRLCLK	South display GPIO_CTL_1 (DDIA) clock
VIO	DDPA_CTRLDATA	South display GPIO_CTL_1 (DDIA) data
AVDD	L_VDDEN	South display panel power sequencing power enable
BKLTEN	L_BKLTEN	South display panel power sequencing backlight enable
PWM	L_BKLTCTL	South display backlight PWM output
DSI 0 TE	Utility Pin	UTIL_PIN_CTL
DSI 1 TE	DSI_DE_TE_2	Enabled automatically by DSI transcoder 1

Pipe to Transcoder to DDI Mappings



Twin modes are not supported. A pipe cannot drive more than one display.

A pipe cannot connect to more than one transcoder simultaneously.

With DisplayPort multistream it is possible to have multiple pipes/transcoders driving a single DDI. Multistream requires at transcoder to be enabled to drive the DP transport, even if the associated pipe streams are disabled.

Transcoders WD* and DSI* do not support multistream.

Two pipes can drive a single display through two transcoders and two DDIs that are joined in the panel (tiled display) or by using DSC compression and joining the pipe outputs to go to a single transcoder and DDI.

Transcoders A-D are tied to the respective Pipes A-D. Each pipe output can go to either the respective transcoder or to transcoders WD* or DSI*.

Pipe A VDSC outputs 2 streams to split the display for eDP Chip on Glass or MSO.

Transcoders A-D can connect to any DDI. Transcoders WD* can only go to system memory. Transcoders DSI* can connect only to DDIA and DDIB.

Mode Set

A mode set sequence is the programming sequence that must be followed when enabling or disabling output to a display. There are several different mode set sequences documented in the following sections. The sequence to use depends on which type of port is being enabled or disabled.

Sequences for Intel MIPI DSI IP

This folder contains the sequences for the Intel MIPI DSI IP.

Sequences for MIPI DSI

These sequences are used to enable and/or disable the new MIPI DSI ports and associated functions. Unless the sequence specifically talks about multi-port requirements (i.e. Dual Link mode) these sequences are for a given DSI port (i.e. either MIPI DSI port can be programmed with the below sequences).

Note that some of the registers outside of the DSI register space still refer to the old naming convention of MIPIA and MIPIC. The DSI ports are no longer associated with specific pipes and, so are referred to as DSI0 and DSI1. The mapping between the old naming convention and the new is: DSI0 = MIPIA; DSI1 = MIPIC

DSI Transcoder Enable Sequence

1. Initialize display (Sequences to Initialize Display)
2. Enable Power Wells
    a. If Pipe A is not being used to drive MIPI DSI, then the power wells for those pipes will also need to be enabled (see Sequences for Power Wells)
3. Enable IO Power
    a. Configure the mode of operation of the IO for MIPI DSI (via **DSI_IO_MODECTL**)
        i. Note that setting the IO mode will assert the HS Word clock (a.k.a. the 1X clock) request to the IO. This will enable the IO to forward the HS Word clock back to the Display Engine
    b. Enable **PWR_WELL_CTL_DDI** Power Requests for the DDI that will be used (DSI0 uses DDI A; DSI1 uses DDI B)
        i. Note that the DPHY automatically powers up the AUX lane (DSI Data Lane 0) when it receives the power request with the IO mode set to MIPI DSI. Do **not** try to power on the AUX channel using the PWR_WELL_CTL_AUX register
    c. Wait for PWR_WELL_CTL_DDI Power Status = Enabled
        i. Timeout after 20us
4. Enable PLL
    a. If PLL is not already enabled, follow Port Clock Programming enable sequence
    b. Configure PLL to port mapping to direct the PLL output to the DDI
    c. If not already done, gate the DDI clock associated with port being enabled (DPCLKA_CFGCR0)
        i. If DSI 0 is being used, then set the DDIA Clock Off bit of DPCLKA_CFGCR0
        ii. If DSI 1 is being used, then set the DDIB Clock Off bit of DPCLKA_CFGCR0
5. Configure and Enable DPHY
    a. Configure PORT_CL_DW10 Static Power Down to power up all lanes of the DDI that will be used
        i. See table below for the mapping of the DSI lanes to the Static Power Down bits
    b. Configure the Lane sequencing of the Combo-PHY transmitters for MIPI DSI HS operation

i. Set the Loadgen Select (**PORT_TX_DW4**) for Transmit lanes 0, 1, and 3 to be secondary to the Aux lane (see Lane Sequence Programming table below)

1. Note that Transmit lane 2 is the DSI Clock lane and it must be a primary lane (i.e. it cannot be secondary to any other lane) for proper operation

ii. Set the Latency Optimization (**PORT_TX_DW2** and **PORT_PCS_DW1**) for the Aux lane and Transmit lanes (see Lane Sequence Programming table below for values)

1. The DSI Clock lane operates independent of the Data lanes, so there is no latency optimization needed

c. Configure voltage swing and skew. Refer to DDI Buffer section for the programming not already specified above (i.e. the Loadgen Select and Latency Optimization should be used from here, all other DDI buffer programming can be taken from the DDI Buffer section).
    i. Note that the voltage swing and skew programming is for the HS data only. The HW automatically handles the swing and skew for the LP data
d. Setup D-PHY timings
    i. If SW is going to override any of the D-PHY timing parameters, then configure DPHY_CLK_TIMING_PARAM, DPHY_DATA_TIMING_PARAM, or DPHY_TA_TIMING_PARAM with the desired D-PHY timings. SW must also program the equivalent DSI_*_TIMING_PARAM registers with the appropriate overrides (see following step)
e. Program Tx Equalization for the port (**PORT_TX_DW0**), if necessary (determined by VBT)
    i. Note that the programming should be applied across all lanes of the PHY, so Software can use the TXGRP offset to program all lanes at once.
f. If the link is operating at 1.5Gbps or below, then program the TX slew rate to 11b in **PORT_TX_DW1**, else program it to 0b0.
g. If the link is operating at 2.5Gbps, then program clock lane (lane 2) o_ldo_ref_sel_cri = 000011b in **PORT_TX_DW6_<lane 2 instance>**, else program it to 000000b.
h. Enable DDI Buffer and wait for DDI_BUF_CTL DDI Idle Status = 0b (Not Idle)
    i. Timeout after 500us

6. Enable DSI Transcoder
    a. Setup link initialization/wakeup timings
        i. Configure the DSI_T_INIT_PRIMARY with the Initialization time if different than the default 100us
        ii. Configure the DSI_T_WAKEUP with the T_{WAKEUP} timing parameter if different than the default 1ms
        iii. If Software overrode the transitional timing parameters for the clock or data lanes within the DPHY (i.e. DPHY_CLK_TIMING_PARAM/DPHY_DATA_TIMING_PARAM registers), then it must reflect those overrides within the DSI controller's timing parameter registers (**DSI_CLK_TIMING_PARAM**, or **DSI_DATA_TIMING_PARAM**)
    b. Enable and configure the **UTIL_PIN_CTL** register as an input, if enabling DSI port 0 to be operating in Command Mode and the TE events will be received out-of-band
        i. This IO is shared with Audio
    c. Enable and configure UTIL2_PIN_CTL as an input, if enabling DSI port 1 to be operating in Command Mode and the TE events will be received out-of-band
        i. This IO is shared with Genlock.
    d. Configure DSI timeouts - **DSI_HTX_TO**, **DSI_CALIB_TO**, **DSI_LRX_H_TO**, **DSI_PWAIT_TO**, and **DSI_TA_TO**.
        i. Note that the DSI_HTX_TO and DSI_CALIB_TO registers don't have to be programmed if Software is satisfied with the defaults.

ii. The "Programming Reference" section below gives some guidelines on how the DSI_TA_TO and DSI_LRX_H_TO registers can be programmed.

e. Configure **TRANS_DSI_FUNC_CONF**

f. Configure **TRANS_DDI_FUNC_CTL2** Port Sync Mode Enable, if both DSI transcoders are going to operate in Dual Link mode

i. See "Dual Link Sequence" below for details

g. Configure and enable **TRANS_DDI_FUNC_CTL**

h. Wait for DSI Link Ready (TRANS_DSI_FUNC_CONF)

i. Timeout after 2X the value programmed in the DSI_T_WAKEUP register + 500us

ii. Note that the timeout duration is to account for the possibility that the DSI Link is in ULPS. When exiting ULPS the controller will have to serialize the wakeup of the Clock Lane and Data Lanes.

7. Program Panel

a. Send a "*Set Maximum Return Packet Size*" DSI packet to the Panel. Refer to "Sending Commands to the Panel" section. This is a Short Packet format, only a Header credit will be needed to form the packet within the **DSI_CMD_TXHDR**register (with the Payload bit cleared). The packet is composed of:

i. Data Type: 0x37

ii. Virtual Channel: Panel specific

iii. Data: The Maximum Return Packet Size can be programmed for up to 32 bytes

b. Software will handle any additional panel setup here.

c. Software needs to ensure that all of the Panel programming has been dispatched before the Transcoder is enabled. To do this, the following sequence will need to be done:

i. Software will wait for all Header and Payload Credits to be released (DSI_CMD_TXCTL)

1. Timeout after 100us

ii. Build a NOP DCS command using the DSI_CMD_TXHDR register

1. The packet will use a Data Type of 0x05 (DCS Short Write - 0 Parameters)
2. The Word Count/Parameter bytes will be set to all zeroes (NOP DCS command)
3. Set the LPDT bit

iii. After loading the NOP with the DSI_CMD_TXHDR write, Software will wait for the following to be true:

1. Wait for all Header Credits to be released
    i. Timeout after 20us
2. Wait for LP Tx in Progress bit of the **DSI_LP_MSG** register to be cleared
    i. Timeout after 20us

iv. Software can now continue the enabling sequence

8. Enable Planes, Pipe, and Transcoder

a. Configure and enable planes (VGA or hires)

i. If VGA, clear VGA I/O register SR01 bit 5
ii. This can be done later, if desired

b. Enable Scaler, if needed (must be enabled for VGA)
c. Configure Transcoder Timings
    i. Make sure to program TRANS_VBLANK appropriately
        1. The Vertical Blank End should always be programmed to be equal to the Vertical Total programming of TRANS_VTOTAL
        2. If the Display Stream Buffer (DSB) is not enabled, then the Vertical Blank Start should be programmed to be equal to the Vertical Active programming of TRANS_VTOTAL
        3. If the DSB is enabled, then the Vertical Blank Start may need to be pushed out
    ii. If operating in Command Mode (a.k.a. DBI), then the Vertical and Horizontal totals should still be programmed even though the DSI transcoder is not truly maintaining these timings.
        1. Program the Horizontal Total to be Horizontal Active + 160
        2. Program the Vertical Total to include a Vertical blanking time that satisfies the following: ceiling(400us / Line Time). See the "**Determining Vertical Blank in DBI**" section within the "Transcoder DSI Function" page for programming details.
    iii. Software does not need to program the TRANS_*SYNC registers, if the DSI transcoder is operating in Command Mode
d. Configure and enable **TRANS_CONF**
    i. Wait for the Transcoder State to be enabled, if additional Panel Commands need to be sent at this time

9. Turn on the backlight, if necessary

The following table shows the mapping of the Static Power Down bits within the PORT_CL_DW10 register and the PWR_WELL_CTL_DDI register to the physical I/O lanes used for a DSI transcoder's link.

Phys Uni-Dir Lane 3 (Bit 3)	Phys Uni-Dir Lane 2 (Bit 2)	Phys Uni-Dir Lane 1 (Bit 1)	Phys Uni-Dir Lane 0 (Bit 0)	Phys Bi-Dir Lane (PWR_WELL_CTL_DDI)	Notes
MIPI DSI Usage					
Data Lane 3	**Clock Lane**	**Data Lane 2**	**Data Lane 1**	**Data Lane 0**	**Lane mapping**
OFF	**ON**	**OFF**	**OFF**	**ON**	**x1 DSI**
OFF	**ON**	**OFF**	**ON**	**ON**	**x2 DSI**
OFF	**ON**	**ON**	**ON**	**ON**	**x3 DSI**
ON	**ON**	**ON**	**ON**	**ON**	**x4 DSI**

Lane Sequence Programming

AFE Lane	DSI Lane	Latency Optimization				Load Generation Select	
		PORT_TX_DW2		PORT_PCS_DW1		PORT_TX_DW4	
		Bits	Value[1]	Bits	Value[2]	Bits	Value
Aux	Data Lane 0	[10:8]	'h5	[3:2]	'h0	[31]	0
0	Data Lane 1		'h5		'h1		1
1	Data Lane 2		'h5		'h1		1
2	**Clock Lane**		**'h0**		**'h1**		**0**
3	Data Lane 3		'h5		'h1		1

1. The Latency Optimization of the Clock Lane can be either left at it's default value ('h0) or programmed to the same value as the other lanes. If programmed with the same value as the other lanes, then the Group access can be used for PORT_TX_DW2 programming
2. The Group access register for PORT_PCS_DW1 can be used to program the non-Aux AFE lanes.

DSI Transcoder Disable Sequence

Note that this sequence is agnostic to whether the transcoder is operating in the Video (i.e. DPI) or Command (i.e. DBI) mode of operation.

1. Turn off Backlight, if desired
2. Disable Planes, Pipe, and Transcoder
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100us
    b. Disable planes (VGA or hires)
    c. Disable **TRANS_CONF**
    d. Wait for off status in TRANS_CONF
        i. Poll TRANS_CONF register or timeout after two frame times
    e. Send any necessary commands to the Panel now
    f. Make sure all commands have been delivered to the Panel
        i. Software will wait for all Header and Payload Credits to be released (**DSI_CMD_TXCTL**)
            1. Poll DSI_CMD_TXCTL or Timeout after 100us
        ii. Build a NOP DCS command using the DSI_CMD_TXHDR register
            1. The packet will use a Data Type of 0x05 (DCS Short Write - 0 Parameters)
            2. The Word Count/Parameter bytes will be set to all zeroes (NOP DCS command)
            3. Set the LPDT bit
        iii. After loading the NOP with the DSI_CMD_TXHDR write, Software will wait for the following to be true:
            1. Wait for all Header Credits to be released
                1. Poll DSI_CMD_TXCTL or Timeout after 20us
            2. Wait for LP Tx in Progress bit of the DSI_LP_MSG register to be cleared
                1. Poll DSI_LP_MSG or Timeout after 20us
    g. Put the Link in ULPS
        i. Configure ULPS Type and Entry in **DSI_LP_MSG**
        ii. Wait for the Link to enter ULPS (logged within the DSI_LP_MSG register) or an interrupt indicating ULPS entry is done
            1. Option to timeout after 10us
    h. Disable **TRANS_DDI_FUNC_CTL**
    i. Wait for 1us to allow the PPI lane enables to propagate to the DPHY
    j. Disable TRANS_DDI_FUNC_CTL2 Port Sync Mode Enable, if both DSI transcoders are operating in Dual Link mode
    k. Disable panel fitter, if enabled

3. Disable Port. Note that if the Port is going to be disabled, then the IO power will have to be disabled as well
    a. Disable **DDI_BUF_CTL**
    b. Wait for 8us or poll on DDI_BUF_CTL Idle Status for buffers to return to idle
4. Disable IO Power
    a. Disable **PWR_WELL_CTL_DDI** IO Power Request for the DDI that was used
    b. Wait for PWR_WELL_CTL_DDI Power Status = Disabled
    c. Configure **DSI_IO_MODECTL**for DDI operation
5. Disable PLL
    a. Configure PLL to port mapping to direct no clock to the DDI
    b. If this PLL is no longer needed, disable
6. Disable Power Wells being used by the transcoder if there are no required resources within the power well

There are two levels of port disablement allowed by the IO when it is operating in the MIPI mode.

Level	ULPS	Disable Buffer	Disable IO Power	Notes
1	x			This will gate the clocks within the IO AFE. This is equivalent to disabling the buffer without disabling the IO power when the IO is operating as a DDI port.
2	x	x	x	This will power gate the IO

Note that it is invalid to put the Link into ULPS and then disable the Buffer without also disabling the IO power. E.g. the following flow is not allowed:

- Enter ULPS
- Disable Buffer
- Re-enable Buffer
- Exit ULPS

Dual Link Enable Sequence

When setting up two DSI transcoder's to be synchronized, there are two different configurations possible:

1. Single Pipe to two ports (Dual Link - Single Pipe)
2. Two Pipes to two ports (Dual Link - Double Pipes)

Notes:

- Currently, only Pipe A can support a Dual Link - Single Pipe configuration.
- The expectation from the DSI transcoders when they are synchronized is:
    - **Only a single PLL is being used to generate the 1X clock**.

- TE events will need to be supplied to both transcoders

The following table illustrates the programming of the TRANS_DDI_FUNC_CTL2 and the configuration of the DSI ports

Dual Pipe Sync	Port Sync Mode	DSI Port configuration
0	0	Port is independent
0	1	Dual Link - Single Pipe
1	0	Not valid
1	1	Dual Link - Dual Pipe

Regardless of the type of synchronization, the following enable sequence will be common:

1. Enable the Power Well. This step is only done once since both Primary and Secondary transcoders are in the same well.
2. Enable IO power. This step will have to be done for **each** IO port
    a. Note that if enabling for Dual Link - Single Pipe (DLSP), then Software can send the Power Requests (PWR_WELL_CTL_DDI) to both IO ports at the same time and then wait for the Power Status = Enabled for both ports
3. Enable the PLL. This step is only done once since both ports should run off of the same PLL.
4. Configure and Enable DPHY will have to be done for **each** IO port
    a. Again for DLSP, Software can enable both buffers at the same time via the DDI_BUF_CTL register and wait for both buffers to go to the Ready state

Beyond this point the enabling sequences will differ slightly.

Dual Link - Single Pipe (DLSP)

When setting up the DSI transcoders for dual link - single pipe mode, DSI Transcoder 0 will always be the primary and DSI Transcoder 1 will always be the secondary. Each transcoder will transmit 1/2 of the image to be displayed by the panel plus any overlap. It is beyond the scope of the DSI transcoder on which portion of the panel image it is transmitting.

The majority of the primary transcoder registers can be mirrored to the secondary transcoder when the Port Sync Mode is enabled within the TRANS_DDI_FUNC_CTL2 register of DSI Transcoder 0 (i.e. the **primary**). This allows Software to perform the enabling sequence for a single DSI transcoder (the primary). **However, Software must:**

1. Power up and enable **both** port IO's before moving to step 5 of the enabling sequence
2. Program the DSI0 transcoder (the primary) first. If Software is not taking advantage of the mirroring done in hardware, then it can program DSI1 (the secondary), but only after programming DSI0.

After the IO's for both ports have been powered up and enabled, Software can move to step 5 of the enabling sequence.

- Again, Software only needs to program the primary registers

- When programming the **TRANS_DDI_FUNC_CTL2** register set the Port Sync Mode Enable, but keep the Dual Pipe Sync disabled
- Configure the **PIPE_DSS_CTL1** register for Pipe A
    - Enable the Splitter
    - Note that Software **cannot** enable the small Joiner in DLSP
    - Select the Dual Link Mode of operation (Front-Back or Interleave)
    - Program the Overlap, if the overlap is non-zero
- Configure the **PIPE_DSS_CTL2** register for Pipe A
    - If compression is being used, then both Left and Right branch VDSC engines will need to be enabled
    - Configure the Right dual link buffer target depth, if required
- Program the DSI Input Select of the **TRANS_DDI_FUNC_CTL** register to Pipe A when enabling the function
- Wait for the DSI Link Ready (**TRANS_DSI_FUNC_CONF**) for **both** ports

Once both transcoder functions are enabled and ready, Software can move to programming the Panels.

- Software will have to do this for each Panel independently
- Software should finish initializing both Panels before moving on

After Software is finished initializing the Panels it can enable the Planes, Pipe A, and Transcoder. When programming the Horizontal Active size, Software will program it for **half** of the total horizontal active size across both Panels. **Software should not include any overlap within this programming** (HW will handle this)

Dual Link - Dual Pipe (DLDP)

When operating in the dual link - dual pipe configuration, each transcoder is being supplied by a separate and independent Pipe (any Pipe can drive a given transcoder as long as it's not the same Pipe).

Since both transcoders are being supplied by separate Pipes there are a few major differences from DLSP

1. The mirroring that occurs with DLSP does not happen (the Dual Pipe Sync bit of DSI 0 will disable it). This means that Software is responsible for programming both ports with identical timings
2. Either port can be disabled and/or enabled on the fly. When a port is enabled in the presence of an already running port Software can have Hardware automatically synchronize the newly enabled port to the already running port.
3. In Command Mode Software will have to initiate Frame Updates to each transcoder independently. The transcoders will ensure both ports start transmitting the frame after both ports have received their TE events

Because both transcoders are essentially independent yet synchronized, the concept of a primary and secondary port changes. A given transcoder that has its Port Sync enabled will draft off of the other port (i.e. the Primary). Not only will the Primary not know that it is being drafted off of by the other port, but it's possible for both ports to be subordinate to each other (i.e. both ports have the Port Sync bit set, so

there is no primary). The latter scenario will be the normal mode of operation when both ports are in Command Mode.

Synchronizing in Video Mode

There are a couple of ways to get the ports synchronized to each other in Video Mode

1. Bring both ports up at the same time where both ports are sync'ed to each other (i.e. both ports have their Port Sync Enable set)
2. Bring the ports up independently where the second port is subordinate to the first port

   When bringing both ports up synchronized at the same time in Video Mode:

   - Power up and enable both port IO's before moving to step 5
   - Software will have to do the following for each transcoder
     - When programming the **TRANS_DDI_FUNC_CTL2** register set the Port Sync Mode Enable and the Dual Pipe Sync Enable
     - Configure the **PIPE_DSS_CTL1** register for the Pipe that will be feeding the transcoder, if needed
       - Software should not enable Splitting
       - Software can enable Joining
     - Configure the **PIPE_DSS_CTL2** register for the Pipe that will be feeding the transcoder, if compression is needed
     - Configure and enable **TRANS_DDI_FUNC_CTL**
       - The DSI Input Select should be different for each transcoder
     - Wait for the DSI Link Ready (**TRANS_DSI_FUNC_CONF**)
     - Program the Panel
     - Enable the Planes and Pipe, but stop short of enabling the Transcoder
       - Note that the Horizontal Active should be programed for the active size of the given Panel
   - When above programming for both transcoders has been complete, then enable both Transcoders (**TRANS_CONF**).
     - Wait for both Transcoder States to be enabled
   - If allowing DC*co, then do that now

   When bringing up a single port to be synchronized to an already running port in Video Mode:

   - The port already running is enabled normally without Port Sync Mode being enabled
   - The new port is enabled normally but it will enable the Port Sync Mode and the Dual Pipe Sync within the **TRANS_DDI_FUNC_CTL2** register

Synchronizing in Command Mode

When in Command Mode, if Software wishes to synchronize the frames between the two ports then it must enable the Port Sync for **both** ports (i.e. both ports have to have the Port Sync Mode and Dual Pipe Sync bits set) before sending the Frame Update Request to either port. The enabling sequence, otherwise, is not unique.

When the transcoders are sync'ed to each other in Command Mode, each transcoder will satisfy the following conditions before starting the transmission of the frame data:

1. This transcoder has met its minimum V. Blank requirements as programmed within the **TRANS_VTOTAL** register
2. This transcoder has received the TE event from its Panel (if TE Gating is enabled)
3. The remote transcoder has met the above two requirements

The transcoders do supply some hooks within the **DSI_CMD_FRMCTL** register for Software to initiate frame updates to the Panels.

- **Single Panel Update**. This attribute will allow a transcoder that is synchronized to another port to send out a frame update without requiring the other port to send a frame
- **Forward Frame Update Request**. This attribute will allow SW to send a single Frame Update Request to a single transcoder and have that transcoder forward the request to the other transcoder
- **Accumulate Frame Update Requests**. This attribute will enable the synchronized transcoders to synchronize the Frame Start to each Pipe

Initializing Panel in LP Escape Mode

Some Panels may require initialization (i.e. Panel programming) to be performed by the Host in the LP Escape mode without the Clock Lane running. After initialization is complete in the LP Escape mode and before the transcoder's timing generator is enabled (TRANS_CONF), the Panel may need the Clock Lane to be running continuously. The following sequence describes the flow needed to reliably perform these Panel requirements.

1. Software will enable the Power Wells, PLL, and IO Power per the above enabling sequence
2. When Enabling the DSI Port and D-PHY, Software will leave the Continuous Clock setting of the TRANS_DSI_FUNC_CONF register to its default value of "Always enter LP after Data Lanes"
    a. Software will otherwise continue the enabling flow within this step normally where the DSI Function will be enabled at the end (TRANS_DDI_FUNC_CTL / TRANS_DSI_FUNC_CONF)
3. Software will perform the Program Panel step normally except it will set the "LPDT" attribute when writing to the DSI_CMD_TXHDR register.
4. When Software has finished sending all of the Panel initialization commands, it will ensure they have all been dispatched by doing the following serialization:
    a. Software will wait for all Header and Payload Credits to be released (**DSI_CMD_TXCTL**)

i. Timeout after 100us

b. Build a NOP DCS command using the DSI_CMD_TXHDR register
   i. The packet will use a Data Type of 0x05 (DCS Short Write - 0 Parameters)
   ii. The Word Count/Parameter bytes will be set to all zeroes (NOP DCS command)
   iii. Set the LPDT bit

c. After loading the NOP with the DSI_CMD_TXHDR write, Software will wait for the following to be true:
   i. Wait for all Header Credits to be released
      1. Timeout after 20us
   ii. Wait for LP Tx in Progress bit of the **DSI_LP_MSG** register to be cleared
      1. Timeout after 20us

5. When Software has finished the above serialization it will program the Continuous Clock setting of the TRANS_DSI_FUNC_CONF register to the desired setting
6. When finished with the above sequence, Software can continue with the enabling sequence and go to the step to enable Planes, Pipe, and Transcoder

Note that this sequence is only for Panels that require initialization in the LP Escape mode. If the Panel does not have this requirement, then Software should perform the normal enabling sequence described above and send the Panel initialization programming in the HS mode.

Sending Commands to the Panel

Software has the ability to send command's to the Panel (e.g. Display Set Command packets) using some specific registers within the DSI transcoder. The DSI transcoder supplies Software with a pool of credits (both header and payload) that Software can use to inject commands onto the DSI Link to the panel.

Command Injection Sequence

1. SW will read the DSI Command Transmission Control register (**DSI_CMD_TXCTL**) to determine how many credits are available.
   a. SW must only use the available credits advertised within the register at the time of the read (i.e. it cannot combine the credits from a previous read)
2. If there are enough credits available for the packet it wishes to build then it will begin issuing writes to the Payload and/or the Header registers
   a. If the packet contains a payload:
      i. SW will use the Payload credits it read in step 1 to write to the Command Payload register (**DSI_CMD_TXPYLD**)
      ii. Every write to DSI_CMD_TXPYLD will load the data written to the register into a payload queue within the transcoder which will consume a Payload resource (i.e. credit)
         1. HW will maintain this credit pool and reflect the current number of available credits within the DSI_CMD_TXCTL register

2. SW can also maintain the credits that it read in step 1 to pipeline the writes to this register, if it has not consumed all of the credits read from that step

iii. SW will write the first DW of the payload first followed by the subsequent DW's of payload data

b. If the packet does not contain a payload, or it has finished writing the payload data to the DSI_CMD_TXPYLD register, it will then write to the Command Header register (**DSI_CMD_TXHDR**) using a Header credit it read in step 1

i. If the packet contains a payload, then SW will:

1. Program the Word Count (WC) field of the packet header to the number of **bytes** within the packet payload that was written to the Payload queue
2. Set the Payload Present attribute

ii. Otherwise, SW will clear the Payload Present attribute when writing the Command Header register

iii. SW will also set the other transmission attributes it wishes to be applied to the packet

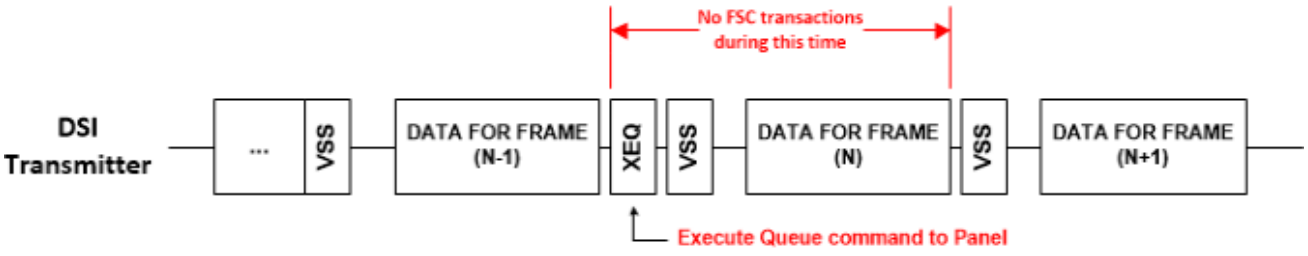
1. The LPDT bit will indicate whether the packet should be sent to the Periphery in the High Speed (HS) or the Low Power (LP) mode
2. The Vertical Blank Fence bit will determine whether the packet will be gated until the next Vertical Blank entry (for Video Mode) or the end of the current frame update is seen

iv. A write to DSI_CMD_TXHDR will load the data written to the register into a header queue within the transcoder which will consume a Header resource (i.e. credit)

1. HW will maintain this credit pool and reflect the current number of available credits within the DSI_CMD_TXCTL register
2. SW can also maintain the credits that it read in step 1 to continue issuing writes to this register, if it has not consumed all of the credits read from that step

Frame Synchronized Command Sequences

The MIPI DSI specification defines a mechanism for the Peripheral to synchronize commands to vertical blanking events internal to the panel. The types of commands that the Peripheral considers to be Frame Synchronized Commands (FSC) is panel specific, but the specification does have restrictions on how and when FSC transactions can be sent to the panel from the Host.



The Vertical Blank Fence attribute within the DSI_CMD_TXHDR is the mechanism within the DSI transcoder that Software can use to ensure these restrictions are met.

Command Mode

1. Load Execute Queue command (Data Type = 0x16) into the **DSI_CMD_TXHDR** register
2. Set the Frame Update Request bit of the **DSI_CMD_FRMCTL** (this can happen at any time after loading the Execute Queue command)
3. If there is another FSC transaction to send, then load it into the DSI_CMD_TXHDR register with the Vertical Blank Fence bit set

Video Mode

1. Load Execute Queue command (Data Type = 0x16) into the DSI_CMD_TXHDR register with the Vertical Blank Fence bit set
2. If there is another FSC transaction to send, then load it into the DSI_CMD_TXHDR register with the Vertical Blank Fence bit set

Low Power Messaging Sequence

1. SW will read the DSI Command Transmission Control register (**DSI_CMD_TXCTL**) to determine if there are any Header credits available.
    a. Each LP message consumes a single Header credit
2. If there is a Header credit available, then Software will program the **DSI_LP_MSG** register with the LP message it wishes to send
    a. If the LP message is either a Trigger or a ULPS Entry, then the respective message type will also need to be programmed
    b. If the LP message is for a ULPS Entry, then Software will need to follow the "DSI Transcoder Disable Sequence" up until step 1.f
3. When HW is servicing the LP message it will advertise the following through the DSI_LP_MSG register:
    a. For all LP messages the transcoder will set the "LP Tx in Progress" bit
    b. The Direction of the Link is always advertised within the register. When doing a Bus Turn-Around, Software will be able to see when the Link changes direction
    c. When doing a ULPS Entry, the register will advertise when the Link has entered the ULP state.
4. When HW is done servicing the LP message it will do the following (Software can key off of any of these to determine when the LP message is complete):
    a. It will clear out the LP message request bit that Software set (i.e. ULPS Entry, Bus Turnaround, or Trigger Message)
    b. Except for ULPS Entry messages, it will clear the "LP Tx in Progress" status bit
        i. For ULPS Entry messages, this bit will not be cleared out until the DSI Function is disabled
    c. For ULPS Entry messages:
        i. The "In ULPS" bit will be set. This bit will be cleared when the DSI Function is disabled

ii. If unmasked, the "ULPS Entry Done" interrupt will be set

5. When done with the ULPS entry, Software can continue with the DSI Transcoder Disable Sequence

Data Receipt Sequence

1. If SW is sending a read to the Panel, then it will follow the "Command Injection Sequence" above to place a read request within the header queue via a write to the **DSI_CMD_TXHDR**. Some notes on this step:
    a. If Software is just looking for an error status from the Panel, then it can go directly to step 2
    b. Before sending a read to the Panel, Software must have sent a "*Set Maximum Packet Size*" DSI packet (Data Type = 0x37) to the Panel to control the amount of data the Panel returns to the Host
    c. The DSI transcoder will send the read command within the next Vertical blank line time that it sees, if operating in Video Mode. If Software wishes the command to be sent at the beginning of the next Vertical blank region, then it can set the Vertical Blank Fence bit when writing to the DSI_CMD_TXHDR
2. SW will write to **DSI_LP_MSG** to place a Bus Turn-Around (BTA) request within the header queue
    a. Prior to this SW should have set up the following (see **Performing LP Transactions in Video Mode** below for more details):
        i. The Turn-Around Timeout (**DSI_TA_TO**) to ensure the BTA request to the Panel proceeds in a timely manner
            1. SW will need to program the equivalent register within the Panel to a time that is less than what is programmed within the DSI_TA_TO register. The command needed to update any registers within the Panel it is beyond the scope of this flow.
        ii. The maximum allowed time the Peripheral will be given to own the Link (**DSI_LRX_H_TO**)
            1. Again, SW will need to program the equivalent register within the Panel with a time that is less than what is programmed within the DSI_LRX_H_TO register
            2. If in Video Mode, the value should be programmed such that the time given to the panel is less than the time between Sync events
        iii. The Peripheral Response Timeout (**DSI_PWAIT_TO**) to give the Panel some time before it has to send back a response.
        iv. If the Panel does not support ECC, then both of the Single and Multi ECC Mask bits of the Interrupt Mask Register (**IMR**) should be set
        v. If the Panel does not support CRC checksums, then the Checksum Error bit of the IMR should be set
    b. Notes:
        i. SW will need a Header Credit to place the Bus Turn-Around request within the Header queue

ii. The DSI transcoder dispatches the commands it receives from Software via the DSI_CMD_TXHDR and DSI_LP_MSG registers in the order they are received

iii. The DSI transcoder will dispatch the BTA at the beginning of the next Vertical blank line time that it sees, if it is in Video Mode. In other words, it will not dispatch the read and the BTA within the same Vertical blank line time.

3. If SW wishes to have HW announce the receipt of the response from the Panel through an interrupt, then it has the following interrupts that it can use. To enable these interrupts, SW should clear the mask bit within the Interrupt Mask Register (IMR)
    a. Rx Trigger: This is for non-TE triggers received from the Panel. If the Panel does not have any return data to send back to the Host, and it has not detected any errors since the last BTA, then it will only send a trigger message (most likely an Acknowledge trigger)
    b. Rx Data/BTA Terminated: HW will generate this type of event when it either receives a response that SW can read from the **DSI_CMD_RXHDR** and/or **DSI_CMD_RXPYLD**, or the BTA was terminated
    c. Error Report: If the Panel detected an error after the last BTA, then it will send an Acknowledge and Error Report packet back to the Host. The error report carried within this packet is sent directly to the interrupt register (the lower 16 bits of the interrupt registers). Depending on the severity of the error, the Peripheral may not send any other responses (i.e. a READ return packet).
4. When the response is received from the Panel, SW will be able to read the header of the response through the DSI_CMD_RXHDR register and the payload, if there is a payload, through the DSI_CMD_RXPYLD register
    a. The payload of the response will be contained within a queue that will be unloaded for every read to the DSI_CMD_RXPYLD register. SW can control whether the DW of data is unloaded from the queue or not through the **DSI_CMD_RXCTL** register
    b. The DSI_CMD_RXCTL register will also advertise the number of DW's available within the payload queue, so SW can use this to determine how many reads it needs to make to DSI_CMD_RXPYLD
5. If the Panel detected any errors since the last BTA, then it will send an Acknowledge and Error Report packet to the Host that will contain the errors that it detected. If the masks for these errors are cleared within the IMR, then SW will have these errors logged within the Interrupt Identity Register (IIR)

Send a Frame in Command Mode

1. During the enabling sequence, Software will:
    1. Setup the source of the Tear Effect (TE) events within the TRANS_DSI_FUNC_CTL register - in-band over the DSI Link or out-of-band through a GPIO.
    2. Choose how the start of the incoming frame pixels are to be handled by the DSI transcoder through the Mode of Operation of the TRANS_DSI_FUNC_CTL register - will it wait for a TE event to be received or not

2. To start a frame, Software will set the Frame Update Request bit of the DSI_CMD_FRMCTL. Hardware will clear this bit once it has begun processing the request.
    1. Note that if configured in Dual Link mode, then only the DSI_CMD_FRMCTL register of the primary port (DSI port 0) will initiate a frame update. However, if Software wishes to observe the Frame in Progress bit of the register, it should look at the secondary port's DSI_CMD_FRMCTL register (DSI port 1) since the secondary port will always be slightly behind the primary port.

Tear Effect (TE) Signaling Sequences

There are three different methods for the Host to get TE information from the Panel:

1. Polling the Panel to detect the current scan line (i.e. using DCS *get_scan_line* commands)
2. Receiving TE events out-of-band (over GPIO)
3. Receiving TE events in-band (over the DSI Link)

For the polling option, Software will simply send out DCS *get_scan_line* requests to the Panel (through DSI_CMD_TXHDR followed by a BTA request through DSI_LP_MSG) until the Display has reached a certain scan line. To receive this information through TE events, Software will need to program the Panel to send these events at specified times (through the DCS *set_tear_on* and *set_tear_scanline* commands). The following is the basic sequences needed to handle receiving TE events.

Receiving Out-of-Band TE Events

1. Software will configure the transcoder to take the TE events from the GPIO when configuring the TRANS_DSI_FUNC_CONF
    a. Software will need to enable and configure the **UTIL_PIN_CTL** register as the TE input for DSI 0
2. During the Panel Programming section of the enabling sequence, Software will configure the Panel to send TE events at the desired times
3. Software will continue the enabling sequence and finally enable the transcoder
4. If TE events are gating:
    a. Software will initiate the Frame Request (DSI_CMD_FRMCTL)
    b. Transcoder hardware will automatically send the frame data to the Panel when it receives the TE event
    c. Software will repeat with a new Frame Request
5. If TE events are not gating:
    a. Software will initiate a Frame Request (DSI_CMD_FRMCTL)
    b. Transcoder hardware will automatically send the frame data to the Panel
    c. Software will repeat with a new Frame Request

Receiving In-Band TE Events

1. Software will configure the transcoder to take the TE events from the DSI receiver when configuring the TRANS_DSI_FUNC_CONF
2. During the Panel Programming section of the enabling sequence, Software will configure the Panel to send TE events (set_tear_on, set_tear_scanline DCS commands)
    a. When operating in Dual Link, both ports will need to be programmed to send the TE triggers
    b. After enabling the tearing on the Panel, a BTA should be sent to the Panel (DSI_LP_MSG) so that the Panel can Acknowledge that the set_tear_* DCS commands were received without any errors
3. Software will continue the enabling sequence and finally enable the transcoder
4. If TE events are gating:
    a. Software will initiate the Frame Request (DSI_CMD_FRMCTL). If in Dual Link Mode, this is done on the Primary port (DSI 0).
    b. Software will send a BTA request to the Panel (DSI_LP_MSG). If in Dual Link Mode, this is done on both ports.
    c. Transcoder hardware will automatically send the frame data to the Panel when it receives the TE event and the Panel turns control back over to the Host
    d. Repeat when the Frame is done (Frame In Progress de-asserts)
5. If TE events are not gating:
    a. Software will initiate the Frame Request (DSI_CMD_FRMCTL). Again, if in Dual Link Mode, then this is performed on the Primary port.
    b. Transcoder hardware will automatically send the frame data to the Panel
    c. When the Frame is done (Frame In Progress de-asserts), Software will send a BTA request to the Panel (DSI_LP_MSG)
        i. If in Dual Link Mode, then Software will monitor the Primary port's DSI_CMD_FRMCTL.Frame In Progress bit, and will send the BTA request on both ports
    d. Repeat when the TE event is received (through either interrupt or DSI_CMD_RXCTL)

Periodic Command Mode

As described above, frame updates sent to the Panel in Command Mode are typically initiated by Software (i.e. Intel's graphics driver). When the Intel graphics driver is not present (e.g. the driver is uninstalled, the OS basic driver is present, or pre-boot time) there will be no frame update requests to the DSI transcoder which will lead to a stale screen. In this situation, the DSI transcoder will have the ability to automatically issue frame updates to the Panel by trapping off of GPIO TE events received from the Panel.

The requirements to enable this feature are:

1. The DSI transcoder will be configured to send Periodic Frame Updates (DSI_CMD_FRMCTL)
    a. By default this feature will be disabled

2. The Panel will need to be configured to send TE events to the Host (i.e. set_tear_on, etc.)
3. The DSI controller will override the programming of the TE Source and TE Gating/Non-Gating when this mode of operation is enabled. The HW overrides will be:
    a. The TE source will be taken from the GPIO. The DSI transcoder HW does not have a mechanism to send Bus Turn-Around's to the Panel
    b. Has to be configured for non-gating Command mode

Switching between Video Mode (DPI) and Command Mode (DBI)

1. Disable the **TRANS_CONF** Transcoder Enable
2. Wait for off status in TRANS_CONF
    i. Timeout if transcoder hasn't moved to the off status after two frame times
3. Change the TRANS_DSI_FUNC_CTL Mode of Operation to the new mode
4. Change any of the other transcoder settings in preparation for Command Mode
5. Re-enable the TRANS_CONF Transcoder Enable
6. If the new mode of operation is Command Mode, then Software can start transmitting frame updates to the Panel using the **DSI_CMD_FRMCTL** register (see "Send a Frame in Command Mode"). Otherwise, the transcoder will automatically start sending frames to the panel

Programming References

Programming references has been moved to the "Transcoder DSI Function" page

Sequences to Initialize Display

These sequences are used to initialize the display engine before any display engine functions can be enabled. To save power, do not initialize display if it will not be used, such as on "headless" systems.

Most display engine functions will not operate while display is not initialized. Only basic PCI, I/O, and MMIO register read/write operations are supported when display is not initialized.

Initialize Sequence

1. Enable PCH Reset Handshake
    a. Set **NDE_RSTWRN_OPT** RST PCH Handshake En to 1b.
    b. Configure south display Raw Clock before first enabling GMBUS, south display hotplug detection, or panel power sequencing.
2. Initialize all combo PHYs with Combo PHY DDI Buffer Combo PHY Initialization Sequence.
3. Enable Power Well 1 (PG1)
    a. Poll for **FUSE_STATUS** Fuse PG0 Distribution Status = 1b.
        - Timeout and fail after 20 us.
    b. Set **PWR_WELL_CTL** Power Well 1 Request to 1b.

- There are two sets of PWR_WELL_CTL registers for software use. It is expected that BIOS uses PWR_WELL_CTL1 and driver uses PWR_WELL_CTL2.

c. Poll for **PWR_WELL_CTL** Power Well 1 State = 1b.
   - Timeout and fail after 30 us (38.4 MHz reference frequency) or 45us (24 MHz reference frequency).
   - Register DSSM Reference Frequency indicates the reference frequency.

d. Poll for **FUSE_STATUS** Fuse PG1 Distribution Status = 1b.
   - Timeout and fail after 20 us.

- Combo PHY Aux IO can be optionally enabled in parallel with PG1 following DDI AUX Channel Aux IO Power Enabling, or it can be enabled later when the Aux will be used.

4. Enable CD clock following the Sequences for Changing CD Clock Frequency
5. Enable first DBUF
   a. Set **DBUF_CTL_<first DBUF>** DBUF Power Request to 1b.
   b. Poll for **DBUF_CTL_<first DBUF>** DBUF Power State = 1b.
      - Timeout and fail after 10 us.
   - Additional DBUFs may be enabled later as needed for the display bandwidth and number of pipes enabled.
6. Setup MBUS. Refer to MBus page for the MBus credits programming.
7. Program BW_BUDDY registers. Refer to Arbiter page.

Un-initialize Sequence

Software should only run the un-initialize sequence as part of DC9. It can conflict with other DC states.

1. Disable all display engine functions using the full mode set disable sequence on all pipes, transcoders, ports, planes, and power wells above PG1.
2. Disable DBUFs
   a. Clear **DBUF_CTL_*** DBUF Power Request to 0b.
   b. Poll for **DBUF_CTL_*** DBUF Power State = 0b.
      - Timeout and fail after 10 us.
3. Disable CD clock following the Sequences for Changing CD Clock Frequency
4. Disable Power Well 1 (PG1) and Aux IO Power.
   a. Follow AUX Channel Aux IO Power Disabling for every Aux that is powered up.
   b. Clear **PWR_WELL_CTL**_* Power Well 1 Request to 0b.
   c. Wait for 10us. Do not poll for the power well to disable. Other clients may be keeping it enabled.
5. Follow Combo PHY DDI Buffer Combo PHY Un-Initialization Sequence for all combo PHYs.

Sequences for DisplayPort

This topic describes how to enable and disable DisplayPort.

The DP transport is within the transcoder. Multi-stream requires a transcoder to be enabled to act as the primary transcoder, hosting the DP transport that consolidates the multiple streams. The primary transcoder's clocking, TRANS_DDI_FUNC_CTL, and DP_TP_CTL must be kept enabled while the multistream DP link is enabled, and not enabled and disabled with the video stream.

Enable Sequence

Display must already be initialized

DDIA Lane Capability Control must be configured prior to enabling any ports or port clocks

1. **Enable Power Wells**
    a. Based on the resources to be used, enable the appropriate power wells following the Sequences for Power Wells
    b. Type-C: Note that AUX power is required for running main link.
2. **If panel power sequencing is required - Enable Panel Power**
    a. Enable panel power sequencing
    b. Wait for panel power sequencing to reach the enabled state
3. **Type-C ports**
    a. Skip this step for TBT.
    b. Program DFLEXDPMLE.DPMLETC* to maximum number of lanes allowed as determined by FIA and panel lane count.
        i. Fixed/legacy/static - Program the number of lanes as per DDI_BUF_CTL DP Port Width Selection
        ii. Dynamic - Program the number of lanes as per DFLEXDPSP.DPX4TXLATC*
4. **Enable Port PLL**
    a. If PLL is not already enabled, follow port clock programming sequence from Clocks section
    b. If PLL to port mapping is flexible, configure PLL to port mapping to direct the PLL output to the DDI
5. **If IO power is controlled through PWR_WELL_CTL - Enable IO Power**
    a. Skip this step if TBT.
    b. If the DDI is going to combo PHY, the PHY must be initialized with the Combo PHY DDI Buffer Combo PHY Initialization Sequence
    c. Enable PWR_WELL_CTL DDI IO Power Request for the DDI that will be used
    d. Wait for PWR_WELL_CTL DDI IO Power Request = Enabled, timeout after 20 us (30us for type-C PHYs with fixed/static/native connectors)
6. **Program DP_MODE**
    a. Skip this step for display attached to Combo PHY and TBT.

b. Program PHY lane0 and lane1 DP_MODE registers according to TypeC PHY programming page.

7. **Enable and Train DisplayPort**
   a. If single stream or multi-stream primary transcoder - Configure Transcoder Clock Select to direct the Port clock to the Transcoder
   b. If single stream or multi-stream primary transcoder - Configure TRANS_DDI_FUNC_CTL DDI Select, DDI Mode Select & MST Transport Select
   c. Configure and enable DP_TP_CTL with link training pattern 1 selected
   d. Configure voltage swing and related IO settings.
      i. Refer to Combo DDI Buffer section for display attached to Combo PHY.
      ii. Refer to Type-C DDI buffer page for all other cases.
   e. Combo PHY: Configure PORT_CL_DW10 Static Power Down to power up the used lanes of the DDI.
   f. Configure and enable DDI_BUF_CTL
   g. Wait for DDI_BUF_CTL DDI Idle Status = 0b (Not Idle), timeout after 1 ms.
   h. Follow DisplayPort specification training sequence (see notes for failure handling)
   i. If DisplayPort multi-stream - Set DP_TP_CTL link training to Idle Pattern, wait for 5 idle patterns (DP_TP_STATUS Min_Idles_Sent) (timeout after 800 us)
   j. Set DP_TP_CTL link training to Normal.
   k. Configure and enable FEC if needed. NOTE: Refer to Bspec "DDI FEC" page for enabling protocol with FEC capable sink.
8. **If not in compliance mode: Enable Planes, Pipe, and Transcoder (repeat to add multiple pipes on a single port for multi-streaming)**
   a. If DisplayPort multi-stream - use AUX to program receiver VC Payload ID table to add stream
   b. Configure Transcoder Clock Select to direct the Port clock to the Transcoder. Skip this step if clock select already programmed above.
   c. Configure and enable planes (VGA or hires). This can be done later if desired.
   d. If VGA - Clear VGA I/O register SR01 bit 5
   e. Configure and enable VDSC if needed.
   f. Enable panel fitter if needed (must be enabled for VGA)
   g. Configure transcoder timings, M/N/TU/VC payload size, and other pipe and transcoder settings
   h. Configure TRANS_DDI_FUNC_CTL2 if port sync mode needs to be configured. Then configure and enable TRANS_DDI_FUNC_CTL.
      i. Please refer to the note below for big joiner mode operation.
   i. Configure VRR if needed. (note: VRR needs to be programmed after TRANS_DDI_FUNC_CTL and before TRANS_CONF).
      i. program TRANS_VRR_VMIN

ii. program TRANS_VRR_VMAX
iii. Enable push bit if required
iv. enable TRANS_VRR_CTL

j. If DisplayPort multistream - Clear ACT sent status in primary
k. If DisplayPort multistream - Enable pipe VC payload allocation in TRANS_DDI_FUNC_CTL
l. If DisplayPort multistream - Wait for ACT sent status in primary transcoder DP_TP_STATUS and receiver DPCD (timeout after >410us)
m. For DP 1.4 MST with FEC, set bit [23] at applicable offset 0x420C0/0x420C4/0x420C8/0x420D8 to '1'.
n. Configure and enable TRANS_CONF
o. If panel power sequencing is required - Enable panel backlight

SRD and/or Audio can be enabled after everything is complete. Follow the audio enable sequence in the audio registers section.

Notes

Changing voltage swing during link training:

- Change the swing setting following the DDI Buffer section. The port does not need to be disabled.

Changing port width (lane count) or frequency during link training:

1. Follow Disable Sequence for DisplayPort to Disable Port.
2. For TBT follow the steps to turn off the clock for the port. Otherwise, if PLL frequency needs to change, follow the Disable Sequence for DisplayPort to Disable PLL.
3. For TBT, follow the steps to map the new frequency to the port and turn on the clock for the port. For all other port types, follow the Enable Sequence for DisplayPort to Enable PLL, using the new frequency settings.
4. Type-C ports: skip this step for TBT.
    a. Program DFLEXDPMLE.DPMLETC* for the new number of lanes (down training)
    b. Program PHY lane0 and lane1 DP_MODE registers for the new number of lanes (down training)
5. Follow the Enable Sequence for DisplayPort to Enable and Train DisplayPort, using the new port width settings.

If the mode set fails, follow the disable sequence to disable everything that had been enabled up to the failing point.

Enabling DisplayPort Sync Mode (non-MST)

See TRANS_DDI_FUNC_CTL2 Port Sync Mode Enable for restrictions.

1. Follow the enable sequence for the DisplayPort secondary, but skip the step that sets DP_TP_CTL link training to Normal (stay in Idle Pattern).
    - Set secondary TRANS_DDI_FUNC_CTL2 Port Sync Mode Primary Select and Port Sync Mode Enable before configuring and enabling secondary TRANS_DDI_FUNC_CTL.
2. Follow the enable sequence for the DisplayPort primary, but skip the step that sets DP_TP_CTL link training to Normal (stay in Idle Pattern).
3. Set DisplayPort secondary DP_TP_CTL link training to Normal.
4. Wait 200 uS.
5. Set DisplayPort primary DP_TP_CTL link training to Normal.

Software may need to use DOUBLE_BUFFER_CTL to ensure updates to plane and pipe registers will take place in the same frame.

For example: If pipe A and pipe B are synchronized together and software needs the surface addresses for two planes to update at the same time, software should use DOUBLE_BUFFER_CTL when writing the surface address registers for both planes, otherwise there is a possibility that the updates could be split across a vertical blank such that one plane would update on the current vertical blank and the other plane would update on the next vertical blank.

Enabling DisplayPort with Big Joiner

Big joiner (such as for 8K on a single port) uses two pipes to drive a single transcoder.

1. Follow the enable sequence through the steps to Enable and Train DisplayPort
2. Follow the steps to Enable Planes, Pipe, and Transcoder for pipe C, but do not configure or enable transcoder C.
3. Follow the steps to Enable Planes, Pipe, and Transcoder for pipe B and transcoder B.

Enabling DisplayPort Sync Mode (MST with 1 DDI)

General constraint is that secondary transcoder has to be enabled first before primary transcoder.

See TRANS_DDI_FUNC_CTL2 Port Sync Mode Enable for restrictions.

1. Follow MST enable sequence for the DisplayPort steps 1 to 7
2. Enable the secondary pipe following the step 8 of MST enable sequence
    1. Skip the steps to enable TRANS_DDI_FUNC_CTL2, TRANS_DPT_PAT, TRANS_DDI_FUNC_CTL and TRANS_CONF.
3. Repeat step 8 of MST enable sequence to enable the primary pipe.
    1. Skip the steps to enable TRANS_DPT_PAT, TRANS_DDI_FUNC_CTL and TRANS_CONF.
4. Set secondary TRANS_DDI_FUNC_CTL2 Port Sync Mode Primary Select and Port Sync Mode Enable before configuring and enabling secondary TRANS_DDI_FUNC_CTL. Configure and enable secondary TRANS_CONF and secondary TRANS_DPT_PAT.
5. Configure and enable primary TRANS_DDI_FUNC_CTL. Configure and enable primary TRANS_CONF and primary TRANS_DPT_PAT.

Enabling DisplayPort Sync Mode (MST with 2 DDIs)

General constraint is that secondary transcoder has to be enabled first before primary transcoder.

See TRANS_DDI_FUNC_CTL2 Port Sync Mode Enable for restrictions.

1. secondary DDI: Follow MST enable sequence for the DisplayPort steps 1 to 7
2. Enable the secondary pipe following the step 8 of MST enable sequence
    1. Skip the steps to enable TRANS_DDI_FUNC_CTL2, TRANS_DPT_PAT, TRANS_DDI_FUNC_CTL and TRANS_CONF.
3. primary DDI: Follow MST enable sequence for the DisplayPort steps 1 to 7
4. Repeat step 8 of MST enable sequence to enable the primary pipe.
    1. Skip the steps to enable TRANS_DPT_PAT, TRANS_DDI_FUNC_CTL and TRANS_CONF.
5. Set secondary TRANS_DDI_FUNC_CTL2 Port Sync Mode Primary Select and Port Sync Mode Enable before configuring and enabling secondary TRANS_DDI_FUNC_CTL. Configure and enable secondary TRANS_CONF and secondary TRANS_DPT_PAT.
6. Configure and enable primary TRANS_DDI_FUNC_CTL. Configure and enable primary TRANS_CONF and primary TRANS_DPT_PAT.

Disable Sequence

SRD and Audio must be disabled first. Follow the audio disable sequence in the audio registers section.

1. **If panel power sequencing is required - Disable panel backlight**
2. **If not in compliance mode: Disable Planes, Pipe, and Transcoder (repeat to remove multiple pipes from a single port for multi-streaming)**
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100 us
    b. Disable planes (VGA or hires)
    c. Disable TRANS_CONF
    d. Clear bit [23] to '0' at applicable offset 0x420C0/0x420C4/0x420C8/0x420D8 if set to '1'.
    e. Wait for off status in TRANS_CONF, timeout after two frame times
    f. If DisplayPort multistream - use AUX to program receiver VC Payload ID table to delete stream
    g. If done with this VC payload
        i. Clear ACT sent status in primary
        ii. Disable VC payload allocation in TRANS_DDI_FUNC_CTL
        iii. Wait for ACT sent status in DP_TP_STATUS (multi-stream use the primary transcoder DP_TP_STATUS) and receiver DPCD
    h. Disable VRR, if enabled.
    i. Disable push bit if enabled.

j. If MST primary transcoder: Disable TRANS_DDI_FUNC_CTL and do not change DDI_Select
    1. All other transcoders: Disable TRANS_DDI_FUNC_CTL with DDI_Select set to None
k. Disable DSS_CTL1 Joiner enable (bit 30) if enabled
l. Disable DSS_CTL2 left VDSC (bit 31) and/or right VDSC (bit 30) if enabled
m. Disable panel fitter
n. If multi-stream secondary transcoder: Configure Transcoder Clock Select to direct no clock to the transcoder

3. **Disable Port (all pipes and VC payloads on this port must already be disabled)**
    a. If multi-stream primary transcoder: Set DDI_Select set to None
    b. Disable DDI_BUF_CTL
    c. Disable DP_TP_CTL (do not set port to idle when disabling)
    d. Disable FEC if it is enabled.
    e. Wait 8 us or poll on DDI_BUF_CTL Idle Status for buffers to return to idle
    f. If single stream or multi-stream primary transcoder: Configure Transcoder Clock select to direct no clock to the transcoder
4. **If panel power sequencing is required - Disable Panel Power**
    a. Disable panel power sequencing
5. **If IO power is controlled through PWR_WELL_CTL - Disable IO Power**
    a. Skip this step for TBT. For all other port types, disable PWR_WELL_CTL DDI IO Power Request for the DDI that was used.
6. **Disable Port PLL**
    a. If PLL to port mapping is flexible, configure PLL to port mapping to direct no clock to the DDI
    b. If this PLL is no longer needed, follow PLL disable sequence from Clocks section
7. **Disable Power Wells**
    a. Disable power wells that are no longer required, following the Sequences for Power Wells

Disabling DisplayPort Sync Mode

1. Follow the disable sequence for the DisplayPort secondary.
2. Follow the disable sequence for the DisplayPort primary.

Disabling DisplayPort Sync Mode (MST with 1 DDI)

1. Follow the disable sequence for the MST DisplayPort secondary pipe but keep secondary VC enabled. Step 2 of Disable Sequence.
2. Follow the disable sequence for the MST DisplayPort primary stream. Step 2 of Disable Sequence.
3. Disable secondary VC.

Disabling DisplayPort Sync Mode (MST with 2 DDIs)

1. Follow the disable sequence for the MST DisplayPort secondary stream. Step 2 of Disable Sequence.
2. Follow the disable sequence for the MST DisplayPort primary stream. Step 2 of Disable Sequence.

Disable Displayport with Big Joiner

1. Follow the steps to disable Planes, Pipe, and Transcoder for pipe B and transcoder B
2. Follow the steps to Disable Planes and Pipe for pipe C
3. Disable port associated with Transcoder B

Sequences for HDMI and DVI

This topic describes how to enable and disable HDMI and DVI.

Enable Sequence

Display must already be initialized

1. **Enable Power Wells**
    1. Based on the resources to be used, enable the appropriate power wells following the Sequences for Power Wells
    2. Type-C static connection: Enable AUX I/O Power. It is required for running the main link, even with HDMI.
2. **Type-C static connection: Program DFLEXDPMLE.DPMLETC* to maximum number of lanes of the port.**
3. **Enable Port PLL**
    a. If PLL is not already enabled, follow port clock programming sequence from Clocks section
    b. If PLL to port mapping is flexible, configure PLL to port mapping to direct the PLL output to the DDI
4. **If IO power is controlled through PWR_WELL_CTL - Enable IO Power**
    a. Enable PWR_WELL_CTL DDI IO Power Request for the DDI that will be used
    b. Wait for PWR_WELL_CTL DDI IO Power Request = Enabled, timeout after 20 us (30us for type-C PHYs with fixed/static/native connectors)
5. **Type-C static connection: Program Type-C PHY DP_MODE register for static x4**
6. **Enable Planes, Pipe, and Transcoder**
    a. Configure Transcoder Clock Select to direct the Port clock to the Transcoder
    b. Configure and enable planes (VGA or hires). This can be done later if desired.
    c. If VGA - Clear VGA I/O register SR01 bit 5
    d. Enable panel fitter if needed (must be enabled for VGA)
    e. Configure transcoder timings and other pipe and transcoder settings

f. Configure and enable TRANS_DDI_FUNC_CTL
g. Configure and enable TRANS_CONF

7. **Enable Port**
    1. Configure voltage swing and related IO settings. Refer to the DDI Buffer section.
    2. If not type-C static connection, configure PORT_CL_DW10 Static Power Down to power up all lanes of the DDI.
    3. Configure and enable DDI_BUF_CTL
    4. Wait for DDI_BUF_CTL DDI Idle Status = 0b (Not Idle), timeout after 500 us.

Audio can be enabled after everything is complete. Follow the audio enable sequence in the audio registers section.

Notes

If the mode set fails, follow the disable sequence to disable everything that had been enabled up to the failing point.

Disable Sequence

Audio must be disabled first. Follow the audio disable sequence in the audio registers section.

1. **Disable Planes, Pipe, and Transcoder**
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100 us
    b. Disable planes (VGA or hires)
    c. Disable TRANS_CONF
    d. Wait for off status in TRANS_CONF, timeout after two frame times
    e. Disable TRANS_DDI_FUNC_CTL with DDI_Select set to None
    f. Disable panel fitter
2. **Disable Port**
    1. Disable DDI_BUF_CTL
    2. Wait 8 us or poll on DDI_BUF_CTL Idle Status for buffers to return to idle
    3. Configure Transcoder Clock Select to direct no clock to the transcoder
3. **If IO power is controlled through PWR_WELL_CTL - Disable IO Power**
    a. Disable PWR_WELL_CTL DDI IO Power Request for the DDI that was used used
4. **Disable Port PLL**
    a. If PLL to port mapping is flexible, configure PLL to port mapping to direct no clock to the DDI
    b. If this PLL is no longer needed, disable it
5. **Type-C static connection: Disable AUX I/O Power for the port**

6. **Type-C static connection: Clear DFLEXDPCSSS.DPPMSTC to '0' for the port**
7. **Disable Power Wells**
    1. Disable power wells that are no longer required, following the Sequences for Power Well

Sequences for WD

Enable Sequence

Display must already be initialized

1. **Enable Power Wells**
    1. Based on the resources to be used, enable the appropriate power wells following the Sequences for Power Wells
2. **Enable Planes, Pipe, and Transcoder**
    a. Configure WD_STRIDE, WD_SURF, and WD_TAIL_CFG
    b. Configure and enable planes (VGA or hires). This can be done later if desired.
    c. If VGA - Clear VGA I/O register SR01 bit 5
    d. Enable panel fitter if needed (must be enabled for VGA)
    e. Configure transcoder timings and other pipe and transcoder settings
    f. Configure and enable TRANS_WD_FUNC_CTL
    g. Configure and enable TRANS_CONF

If the mode set fails, follow the disable sequence to disable everything that had been enabled up to the failing point.

Disable Sequence

If using Triggered Capture Mode (TRANS_WD_FUNC_CTL) wait for the frame to complete (polling WD_FRAME_STATUS Frame Complete or using the WD Frame Complete interrupt) before starting the disable sequence.

1. **Disable Planes, Pipe, and Transcoder**
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100 us
    b. Disable planes (VGA or hires)
    c. If using triggered capture mode, wait for current capture to complete, and do not trigger any more captures
    d. Disable TRANS_CONF
    e. Disable TRANS_WD_FUNC_CTL
    f. Disable panel fitter
2. **Disable Power Wells**

1. Disable power wells that are no longer required, following the Sequences for Power Wells

Sequences for Display C5 and C6

Display C5 (DC5) is a power saving state where hardware dynamically disables power wells and PLLs and saves the associated registers.

DC5 can be entered when software allows it, only certain power wells are enabled, and hardware detects that all pipes are disabled or low power pipe(s) are enabled with PSR active.

Display C6 (DC6) is a deeper power saving state where hardware dynamically disables power and saves the associated registers.

DC6 can be entered when software allows it, the conditions for DC5 are met, and the PCU allows DC6.

DC6 is required for S0ix.

The context save and restore program is reset on cold boot, warm reset, PCI function level reset, and hibernate/suspend.

Pipe 3D LUT contents are lost during DC5 and DC6.

Ports A IO/PHY programming is preserved when DC6 is enabled. The programming for other combo PHY ports may not be. After disabling DC6, before enabling the other ports, follow the combo phy initialization sequence and enable Aux IO Power for those ports.

Sequence to Allow DC5 or DC6

1. Load the correct stepping specific Display Context Save and Restore (CSR) program from the binary package.
    a. Read the package header and extract the correct individual firmware. Binary package format details can be found in sections below.
    b. Skip the header section at the start of the program binary.
    c. Copy the payload into Display CSR Program Storage.
    d. Perform the MMIO writes specified in the header section.
2. Configure display engine to disable power wells from table below, following the appropriate mode set disable sequences for any ports using those power wells. This can be done earlier if desired. DMC will prevent entry if these wells are not disabled.
    - Disable power wells PG3 and greater
3. Set display register 0x45520 bits [1:0] to 2'b11. The bits do not need to be cleared at any time.
4. Set DC_STATE_EN Dynamic DC State Enable = "Enable up to DC5" for DC5 or "Enable up to DC6" for DC6.

Programming Note	
Context:	Display C5 and C6
Do not switch between "Enable up to DC5" and "Enable up to DC6" without moving to "Disable" and reloading the CSR program in between. Disable DC5/DC6 during mode set and re-enable after the mode set programming is completed. Disable DC5 and DC6 before a DDI AUX channel transaction is sent. MMIO accesses have more latency when DC5/DC6 is enabled. For optimal performance, disable DC5/DC6 when programming a set of registers and re-enable them after the programming is completed.	

Sequence to Disallow DC5 and DC6

1. Set DC_STATE_EN Dynamic DC State Enable = "Disable".

MIPI DSI

Hardware does not support DC5 or DC6 with MIPI DSI enabled.

DMC Firmware Package

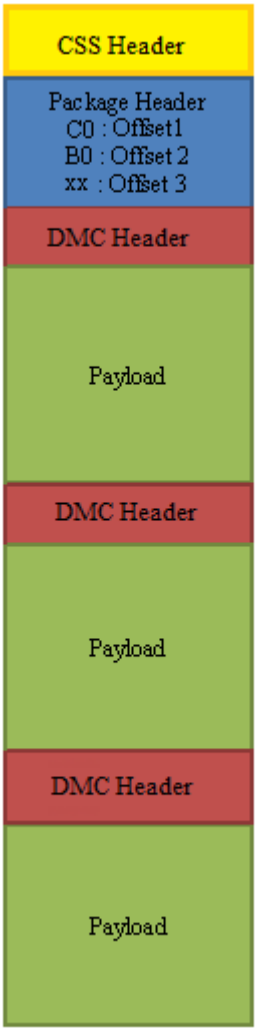
Display Micro-Controller firmware package includes all the firmwares that are required for different steppings of the product. The stepping dependent firmwares are all packaged and released as a single binary package. The package contains the CSS header, followed by the package header and the actual DMC firmwares.

Packaged firmware uses the following naming convention - <project>_dmc_ver<major>_<minor>.bin. The major version will get incremented whenever there is a change in the header layout and would require an update to the driver firmware loading module.

Major version 2

CSS Header	1.0
Package Header	2
DMC Header	3

Package Layout



CSS Header

```
typedef struct _CssHeader {
uint32_t moduleType; // 0x09 for DMC
uint32_t headerLen; // CSS header length in dwords
uint32_t headerVer; // 0x10000
uint32_t moduleID; // Not used
uint32_t moduleVendor; // Not used
uint32_t date; // YYYYMMDD(YYYY « 16 + MM « 8 + DD)
uint32_t size; // Total dmc fw binary size in dwords - (CSS_Headerlen +
PackageHeaderLen + dmc FWsLen)/4
uint32_t keySize; // Not used
uint32_t modulusSize; // Not used
```

```
uint32_t exponentSize; // Not used
uint32_t reserved1[12]; // Not used
uint32_t version; // Major Minor
uint32_t reserved2[8]; // Not used
uint32_t uKernelHeaderInfo; // Not used
} CssHeader;
```

Package Header

Package header contains the firmware/stepping mapping table and the corresponding firmware offsets to the individual binaries, within the package. Mapping table will list the exceptions first, followed by the default entries. An Offset value of "0xFFFFFFFF" in the mapping table indicates that there is no firmware available/supported for that stepping. The offsets to the individual binary are DWord aligned. The first individual binary starts at an offset value of "0x00000000" after the CSS Header and the Package Header.

Stepping/Version mapping example

Stepping	FW Version
A1	1.1
B*	1.6
**	2.3

DMC IDs

DMC	DMC ID
Main	0
Pipe A	1
PipeB	2
PipeC	3
PipeD	4

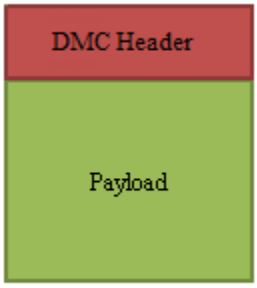
```
typedef struct _PackageHeader {
uint8_t headerLen; // DMC package header length in dwords
uint8_t headerVer; // 0x02
uint8_t reserved[10]; // Reserved
uint32_t numEntries; // Number of valid entries in the FWInfo array below
struct _FWInfo_ {
uint8_t reserved1; // Reserved
uint8_t dmc_id; // DMC ID (Main-0, pipeA-1, pipeB-2, pipeC-3, pipeD-4)
```

```
char stepping; // Stepping (A, B, C, ..., *). * is a wildcard
char substepping; // Sub-stepping (0, 1, ..., *). * is a wildcard
uint32_t offset; // FW offset within the package in dwords
uint32_t reserved2; // Reserved
} FWInfo[32];
} PackageHeader;
```

DMC firmware binary

Each individual DMC firmware binary has a header followed by a payload whose size is specified in the header section. Along with the version, length, firmware size etc. the header section also specifies a list of MMIO addresses and data. These MMIO write cycles, in the 0x80000 - 0x8FFFF address range, should be executed as part of the initial CSR program setup.

DMC firmware Layout



```
for i = 1 to <mmioCount>
Perform MMIO write to address <mmioaddr[i]> with data <mmiodata[i]>
```

DMC Header - Version 3

```
 typedef struct _DMCHeader {
       uint32_t     signature;                        // 0x40403E3E
       uint8_t             headerLen;                        // DMC specific header length in
dwords       uint8_t             headerVer;                        // 0x03       uint16_t
       dmccVer;                        // dmcc compiler version
       uint32_t     project;                          // Major, Minor: 0x00090000, 0x00090001,
0x000A0000
       uint32_t     fwSize;                                 // Firmware program size in dw
       uint32_t     fwVersion;                        // Major Minor
       uint32_t     startMMIOAddr;                           // DMC RAM start MMIO address
       uint32_t     reserved[9];
       uint8_t             dfile [32];                           // .d file name (encoded using
ascii - 40)

  uint32_t mmioCount; // number of mmio uint32_t mmioaddr[20]; // MMIO address uint32_t
mmiodata[20]; // MMIO data

} DMCHeader;
```

Header field	Value
project	0x000C0000

eDP Sequences for Display C3 Clock Off

eDP Display C3 Clock Off (DC3co) is a power saving state where hardware dynamically disables the CDCLK PLL, DBUF power, and Panel Fitter power when PSR2 is idle between frame updates.

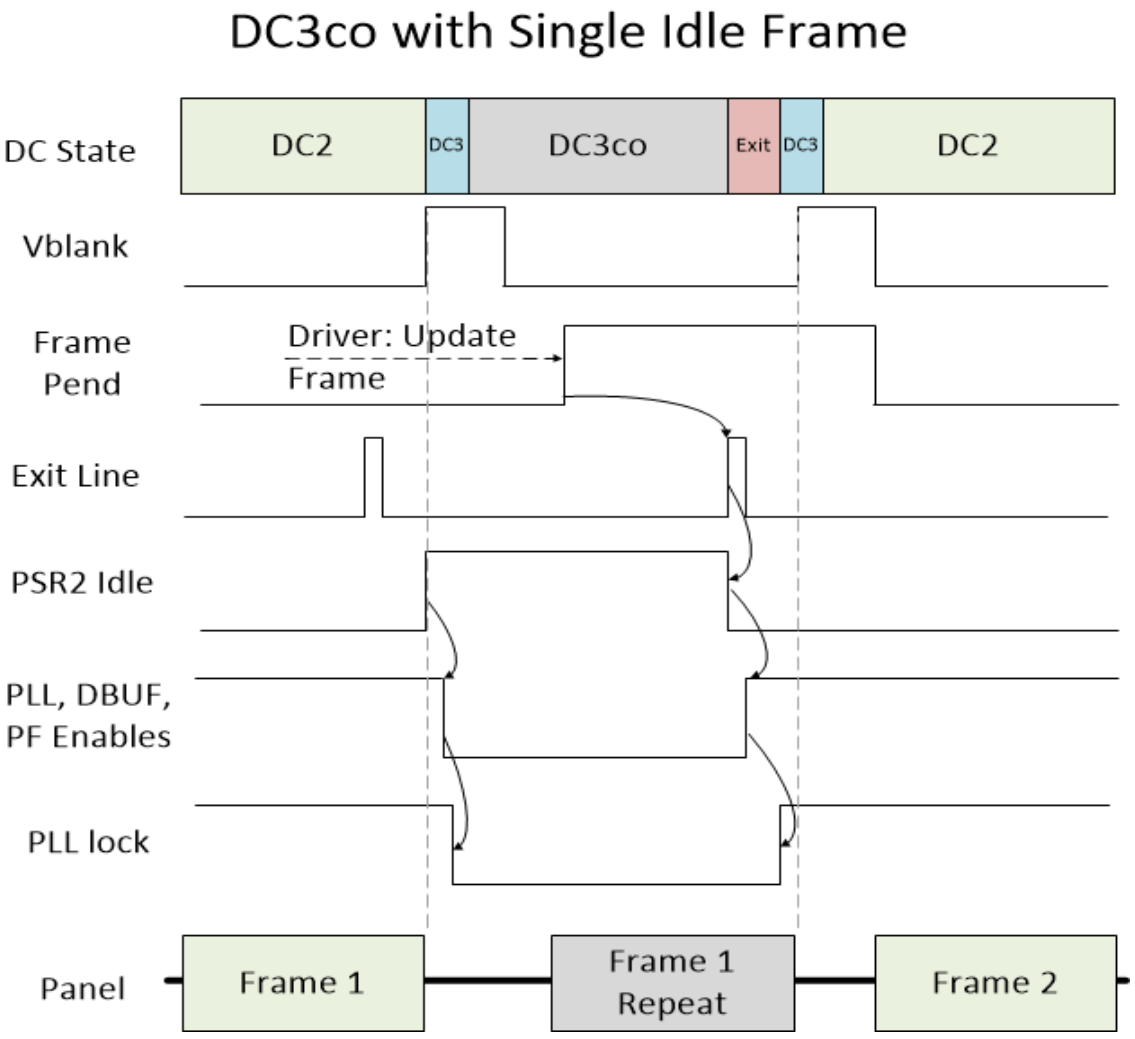
DC3co is entered when software allows it and hardware detects that PSR2 is idle.

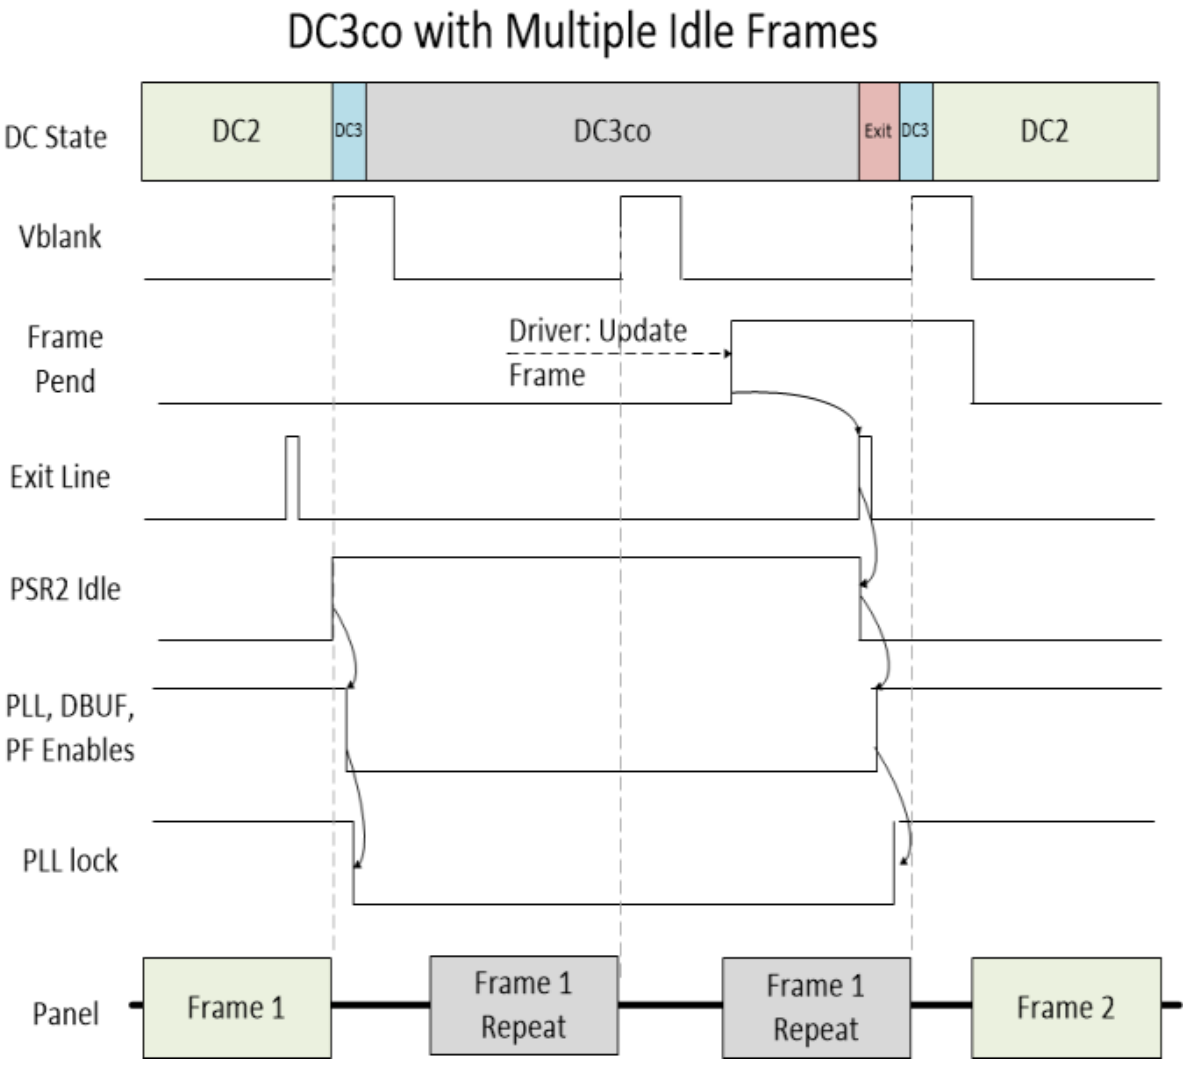
When the CDCLK PLL is disabled, display engine runs CDCLK from a slower SoC clock to maintain accessibility.

DC3co is exited when software disallows it or PSR2 becomes active to send an updated frame.

DC3co is controlled by a context save and restore program which has to be loaded before allowing DC3co and is reset on DC9, cold boot, warm reset, PCI function level reset, and hibernate/suspend.

DC3CO will not work with pipeA and DDIB combination. It only works with pipeA and DDIA.





Requirements

Audio codec idle and disabled.

External displays disabled. WD transcoders and DP/HDMI transcoders must be disabled.

Backlight cannot be driven from the display utility pin. It can be driven from the south display.

This feature should be enabled only on eDP.

DC5 and DC6 not allowed when this feature is enabled.

- DC5 and DC6 saves more power, but cannot be entered during usages like video playback because there are not enough idle frames in a row to meet most panel PSR2 deep sleep entry requirements (typically 4 frames). Software must select between DC5 and DC6 versus DC3co based on flip rate or other hints.

PSR2 deep sleep disabled (PSR2_CTL Idle Frames = 0000b).

Disable DC3co before mode set, or other Aux, PLL, and DBUF programming, and do not re-enable until after that programming is completed.

DC3co is only compatible with PSR2. Follow the sequences to enable and disable PSR2 and DC3co at the correct times.

Sequence to Allow DC3co

1. If not already loaded, load the correct stepping specific Display Context Save and Restore (CSR) program from the binary package.
    a. Read the package header and extract the correct individual firmware. Binary package format details explained in the Sequences for Display C5 and C6 section.
    b. Skip the header section at the start of the program binary.
    c. Copy the payload into Display CSR Program Storage.
    d. Perform the MMIO writes specified in the header section.
2. Configure display engine to meet the requirements for DC3co, following the appropriate disable sequences. This can be done earlier if desired.
    1. Disable DC states by programming DC_STATE_EN Dynamic DC State enable = 00b
    2. Disable PSR2 following the Panel Self Refresh section PSR2 disable sequence.
    3. Disable PSR2 deep sleep by programming PSR2_CTL Idle Frames = 0000b
    4. Enable PSR2 following the Panel Self Refresh section PSR2 enable sequence.
3. Configure and enable the PSR2 transcoder's Early Exit line (TRANS_EXITLINE)
    a. DC3co exit time = Polling rate + instruction execution time + delays from driver MMIO access + DBUF enable time + PLL lock time + guardband = 200us
    b. ROUNDUP(DC3co exit time / line time) + 1
4. Set DC_STATE_EN Display Clock Off Enable = 1b.

Sequence to Disallow DC3co

1. Clear DC_STATE_EN Display DC*CO State Status by writing a 0 to it.
2. Set DC_STATE_EN Display Clock Off Enable = 0b.
3. Wait DC3co exit time for disable to complete. See above for exit time latency calculation above.
    - This ensures exit has completed and it is safe to do things such as program PLL or DBUF registers.
4. Disable PSR2 following the Panel Self Refresh section PSR2 disable sequence.
5. Restore PSR2 deep sleep by programming correct allowed Idle Frames in PSR2_CTL.
6. If PSR2 is still needed, re-enable PSR2 following the Panel Self Refresh section PSR2 enable sequence.

Sequences for Display C9

Display C9 (DC9) is a power saving state where the display engine is powered off.

DC9 supports S0ix with more power savings than DC6.

Display software must follow certain programming sequences to allow or dis-allow DC9.

Hardware will dynamically enter and exit DC9 when allowed, saving and restoring some of the display state.

Sequence to Allow DC9

1. Follow Sequence to Disallow DC5.
2. Disable all display engine functions using the full mode set disable sequence on all pipes, transcoders, ports, planes, and power wells above PG1.
3. Disable and mask all graphics interrupts in north and south display.
4. Save state of MMIO display registers.
    - The exact registers depend on software policy.
    - Hardware will save and restore the PCI Config and DGunit registers
5. Follow Sequences to Initialize Display - Un-initialize Sequence.
6. Set DC_STATE_EN DC9 Allow to 1b.

Sequence to Disallow DC9

1. Clear DC_STATE_EN DC9 Allow to 0b.
2. Follow Sequences to Initialize Display - Initialize Sequence.
3. Restore state of MMIO display registers:
    - The exact registers depend on software policy.
    - The context save and restore program is reset on DC9 and has to be restored.
4. Enable and unmask graphics interrupts as needed.

Xe_{D+} Resolution Support

A display resolution is only supported if it meets all the restrictions below for Maximum Pipe Pixel Rate, Maximum Port Link Rate, Maximum Size, Maximum Bandwidth, and Maximum Watermark.

Core Display Clock (CDCLK)

Refer to the Clocks section for details of the frequencies.

Maximum Pipe Pixel Rate

The display resolution must fit within the maximum pixel rate output from the pipe.

For each enabled plane on the pipe {

    If plane scaling enabled {

        Plane Ratio = 1 / Plane down scale amount

Refer to the Watermark Calculations section, Scaling sub-section, for down scale calculation.

}

Else {

Plane Ratio = 1

}

}

Pipe Ratio = Minimum Plane Ratio of all enabled planes on the pipe

If pipe scaling is enabled {

Pipe down scale amount = Horizontal down scale amount * Vertical down scale amount

Refer to the Watermark Calculations section, Scaling sub-section, for down scale calculation.

Pipe Ratio = Pipe Ratio / Pipe down scale amount

}

Pipe maximum pixel rate = 2 * CDCLK frequency * Pipe Ratio

YUV420 Full Blend Mode

Pipe Maximum Y channel pixel rate = 2 * CDCLK frequency * Y channel Pipe ratio

Resolutions Requiring Joined Pipes

For resolutions requiring multiple pipes to be combined together (pipe joining), the pixel rate seen by each pipe is 1/<# of joined pipes> of the pixel rate of the full resolution.

The overlapping excess horizontal pixels added for scaling smoothly across the seam between pipes do not impact the pixel rate.

For example: 7680x4320 CVT1.2 RB1 pixel rate is 2089.75 MHz. That is split across 2 pipes, so each pipe is 3840x4320 with a pixel rate of 1044.875 MHz.

Maximum Port Link Rate

The display resolution must fit within the maximum link rate for each port type.

Refer to the project overview sections for the maximum rates.

YUV420 Full Blend Mode

Maximum Port Link Rate = CDCLK frequency * Y channel Pipe Ratio * (bits per color / 8)

Maximum Size

There are limits on the maximum horizontal and vertical size.

Plane stride maximum listed in PLANE_STRIDE register.

Multiple pipes can be joined together side by side in the display engine to drive a single port or a tiled panel.

Unjoined pipe source size, plane size, and pipe active size maximum vertical 4096.
Unjoined pipe source size, plane size, and pipe active size maximum horizontal 5120.
Joined pipes active size maximum is 7680x4320, with each pipe and maximum horizontal plane size at 7680/<# of joined pipes> and vertical size at 4320, plus extra overlapping horizontal pixels for scaling excess.
PSR2 maximum pipe horizontal active size 5120 pixels. PSR2 has additional restrictions on minimum vblank size and horizontal total line time. See the PSR section for those.
LACE DPST maximum size 5120x3200 pixels.
Pipe scalers maximum horizontal source size 5120 pixels.

Maximum Bandwidth

Refer to the Bandwidth Restrictions section

Maximum Watermark

The display resolution must not exceed the level 0 maximum watermark value. See the section on Watermark Programming.

Example Display Resolution Capabilities

Refer to the project overview sections for the common resolutions that meet all the resolution restrictions.

Examples

Example pipe pixel rate

Plane 1 enabled at 64bpp and plane down scale amount 1.25, plane 2 enabled at 32bpp, no pipe scaling enabled, and CDCLK 312 MHz:

Plane 1 ratio = 1/1.25 = 0.8

Plane 2 ratio = 1

Pipe ratio = Minimum[1, 0.8] = 0.8

Pipe maximum pixel rate = 2 * 312 MHz * 0.8 = 499.2 MHz

Bandwidth Restrictions

There are bandwidth restrictions that limit the display resolution and configuration. A display resolution is only supported if it meets all the restrictions below for Maximum Memory Read Bandwidth found from the Available Memory Bandwidth Calculation and Required Memory Bandwidth Calculation, Maximum Data Buffer Bandwidth, and Maximum Pipe Read Bandwidth.

Maximum Memory Read Bandwidth

The display required memory bandwidth for a resolution configuration must not exceed the available memory bandwidth, considering efficiency and GV points.

Calculate the available memory bandwidth and the required memory bandwidth across all GV points. Refer to the SAGV chapter for the flow to find GV points and restrict those that do not provide enough available memory bandwidth. If no points provide enable available memory bandwidth, then the display configuration can not be supported.

Note: These calculations are valid even if GV points are disabled. They then use the single available GV point.

Available Memory Bandwidth Calculation

This calculates the memory bandwidth available for display. It considers the efficiency, impacted by memory type and configuration details and number of enabled planes, and differences between GV points.

The InitializeBandwidthAndPlanes function populates arrays with the bandwidth and number of planes that can be enabled in several groupings for each GV point. See the SAGV chapter for information on retrieving the memory configuration to populate the structs at the start of the function.

The CalculateMaxBW function returns the bandwidth available for a specified number of enabled planes and GV point.

```
#define MIN(a, b) (a < b ? a : b)
 #define MAX(a, b) (a > b ? a : b)

 inline int divide_roundup(int n, int d) {
   return (n + d - 1) / d;
 }

 inline int isYtile() {
   return TRUE if any plane is using tileY surface format, and do not count tile4 as tileY
 }

 struct PCODE_GLOBAL_INFO
 {
   uint32_t DdrType : 4;

```

Required Memory Bandwidth Calculation

This calculates the display required memory bandwidth.

Note on planar formats: The NV12 format counts as 2 planes of 2 Bpp each. The P01x formats count as 2 planes of 4 Bpp each. Vertical sub-sampling does not reduce this calculation because the bandwidth has to be counted over a few microsecond period.

DBUF maximum data buffer bandwidth MB/s = CDCLK frequency MHz * 64 Bytes

For each DBUF {

DBUF maximum pipe bandwidth MB/s = DBUF maximum data buffer bandwidth / number of enabled pipes using this buffer

For each pipe using this buffer {

Pipe cumulative bytes per pixel = 0

DBUF maximum plane bandwidth MB/s = DBUF maximum pipe bandwidth / number of enabled planes

For each plane enabled on the pipe { // cursor can be ignored because it only impacts bandwidth for a very short time

Plane required bandwidth MB/s = pixel rate MHz * source pixel format in bytes * plane down scale amount * pipe down scale amount

Display required memory bandwidth MB/s += Plane required bandwidth

Pipe cumulative bytes per pixel += plane source pixel format in bytes

If plane required bandwidth > DBUF maximum plane bandwidth {Return: Failure maximum data buffer bandwidth is exceeded}

}

If pipe cumulative bytes per pixel> (CDCLK frequency MHz /(pixel rate MHz * plane down scale amount * pipe down scale amount)) * 51.2 {Return: Failure maximum pipe read bandwidth is exceeded}

}

}

Return: Display required memory bandwidth MB/s

Maximum Data Buffer Bandwidth

The display resolution must not exceed the maximum bandwidth from each display data buffer (DBUF). There are multiple buffers that can be enabled, and planes can be allocated data blocks from multiple. See the Display Buffer Programming section for requirements on how and when to use multiple buffers.

This is calculated as part of the Required Memory Bandwidth Calculation where it returns a failure if maximum data buffer bandwidth is exceeded. The calculation for this check can be separated out if required.

Maximum Pipe Read Bandwidth

The display resolution must not exceed the maximum memory read bandwidth from each display pipe. This restriction is met by limiting the cumulative bytes per pixel for the pipe, which accounts for the limits of memory reads, translation reads, and data buffer reads.

This is calculated as part of the Required Memory Bandwidth Calculation where it returns a failure if maximum pipe read bandwidth is exceeded. The calculation for this check can be separated out if required.

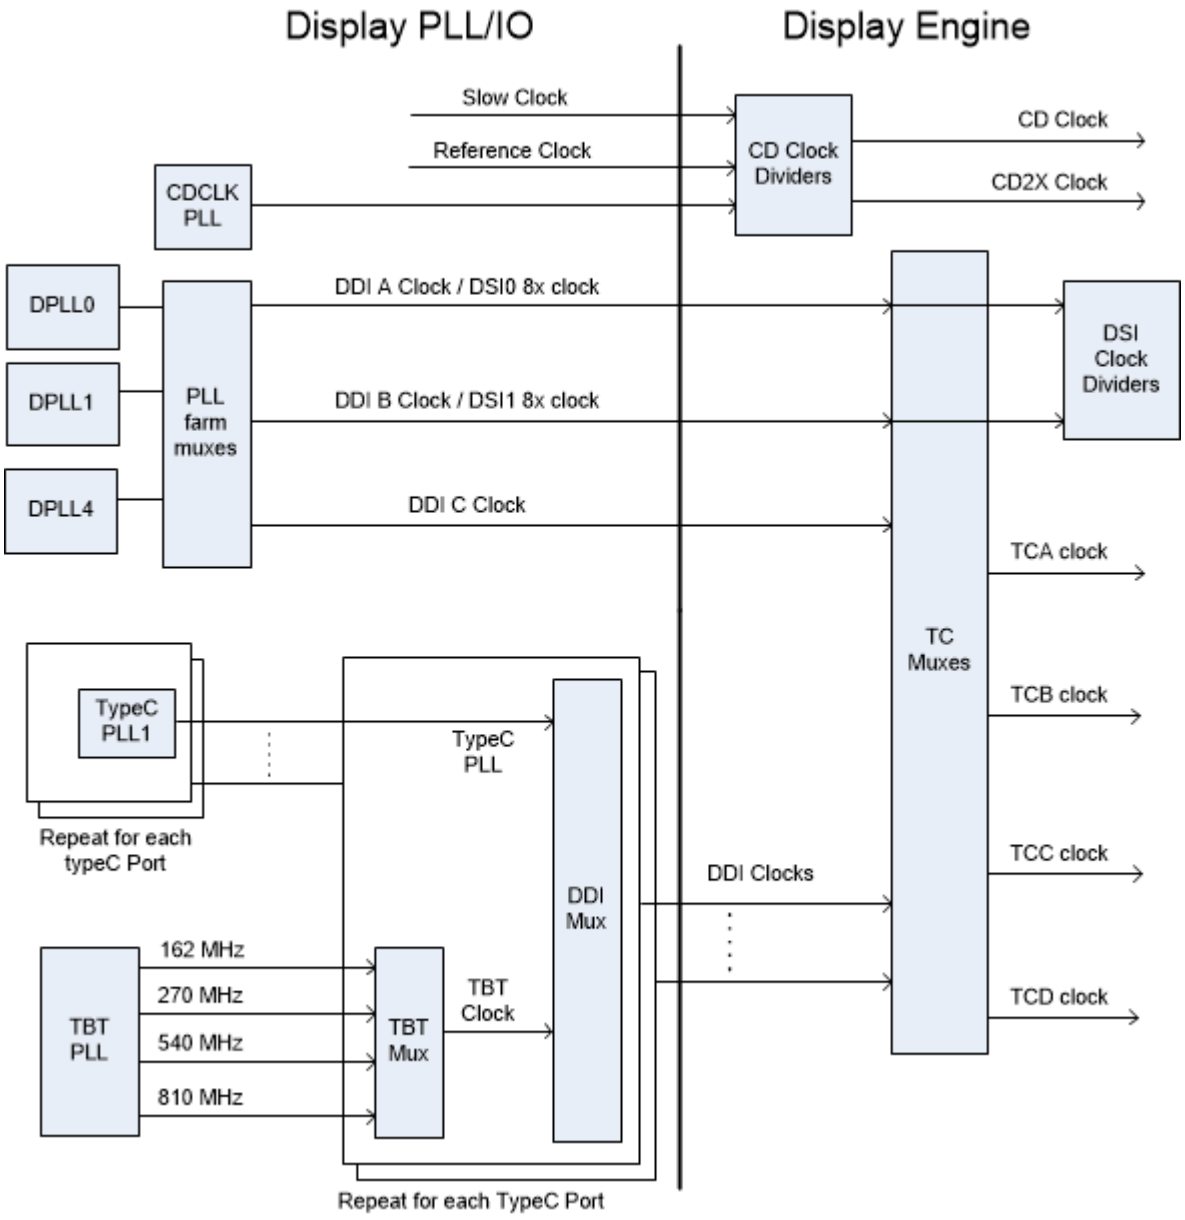
Overview of Display Clock Paths

The display engine clocking structure has multiple PLLs and clocks. The flow is from PLL to DDI (port) clock to transcoder clock.

PLL Arrangement



Display Engine Clock Reference

There is one display engine clock reference.

	Reference
Usage	Reference for the PLLs and for miscellaneous timers in display engine
Frequency	19.2, 24, 38.4 MHz Non-SSC (Register DSSM Reference Frequency indicates the frequency)
Default after reset	Enabled
Programming	Not programmable by display software.

Combo PHY PLLs

DPLLs are used for the combo PHY ports.

The PLL output frequencies are 5x the symbol/TMDS rate, which is 1/2 the bit rate.

The PLL output is divided by 5 to become the symbol/TMDS clock frequency used in the display engine.

Both edges of the PLL output are used in the I/Os to double the frequency to bit clock rate.

A single PLL output may be used by multiple ports simultaneously if those ports all require the same frequency and spread characteristics.

	Combo PHY PLLs (DPLLs)
Usage	Sources for DSI0, DSI1 clocks, and DDI clocks for the combo PHY ports (non-typeC)
Input	Reference clock
Frequency	Programmable eDP/DP link bit rates: 1.62, 2.16, 2.7, 3.24, 4.32, 5.4, 6.48*, 8.1* GHz, SSC and Non-SSC HDMI/DVI symbol rates: 20 to 600 MHz, Non-SSC** DSI 8x clock rates: 0.340 - 2.5 GHz, SSC and Non-SSC *OEM must use VBT to specify a miximum that is tolerated by the board design. *Frequencies between 500 and 533.2 MHz (exclusive) not supported
Default after reset	Disabled
Programming	Must be programmed by software when enabling and disabling a display output. See the section on Port Clock Programming. PLLs are automatically disabled and re-enabled by hardware for some power states.

Thunderbolt (TBT) PLL

DPLL2 is used for thunderbolt ports.

The PLL output is the symbol clock frequencies used in the display engine.

This PLL is used to deliver symbols from the display engine to the thunderbolt controller. The thunderbolt controller will re-clock and convert the symbols to the thunderbolt format.

The PLL outputs all 4 thunderbolt frequencies simultaneously.

	TBT PLL
Usage	Source for DDI clocks on typeC ports when using thunderbolt
Input	Reference clock
Frequency	PLL fixed frequency divided to give simultaneous DP thunderbolt link rates: 162, 270, 540, and 810 MHz, Non-SSC* *SSC, if needed, will be applied on the link by the thunderbolt controller
Default after reset	Disabled
Programming	Must be programmed by software when enabling and disabling a display output. See the section on Port Clock Programming.

TypeC PLLs

The TypeC PLLs are used for Type C ports. There are 2 TypeC PLLs per port, but display engine can only use one PLL, which the register offsets select.

The PLL output frequencies are 5x the symbol/TMDS rate, which is 1/2 the bit rate.

The PLL output is divided by 5 to become the symbol/TMDS clock frequency used in the display engine.

Both edges of the PLL output are used in the DDI I/Os to double the frequency to bit clock rate.

The TypeC PLL is also called a Dekel (DKL) PLL.

	TypeC PLL per port
Usage	Sources for DDI clocks on type C ports when using DP alternate mode or legacy DP or HDMI connectors
Input	Reference clock
Frequency	Programmable eDP/DP/DP-altmode link bit rates: 1.62, 2.7, 5.4, 8.1 GHz, SSC and Non-SSC HDMI/DVI symbol rates: 20 to 600 MHz, Non-SSC
Default after reset	Disabled

Programming	Must be programmed by software when enabling and disabling a display output. See the section on Port Clock Programming.

DDI clocks

There is one DDI clock tied to each DDI port.

A single DDI clock output may be used by multiple transcoders simultaneously for DisplayPort Multi-streaming.

	Combo PHY (non-typeC) DDI clocks	**TypeC DDI clocks**
Usage	DDI ports I/O bit clock and symbol/TMDS clock, source for transcoder clocks	
Input	Programmable selection between the DPLLs	Programmable selection between TypeC PLLs and TBT PLL outputs
Frequency	DPLL frequency	TypeC PLLs or TBT frequency
Default after reset	Disabled	
Programming	Must be programmed by software when enabling and disabling a display. Programming is done through the DPLL, PORT_CLK_SEL, TypeC, and TBT registers. See the section on Port Clock Programming.	

Transcoder Clocks

There is one Transcoder clock tied to each display transcoder.

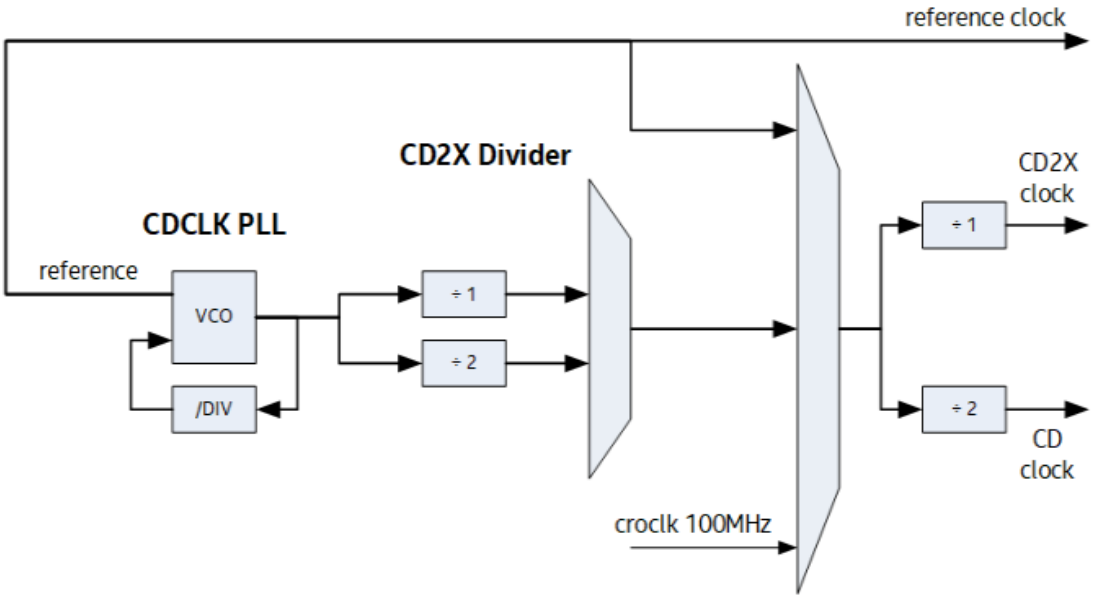
	Transcoder clocks
Usage	Transcoder symbol/TMDS clocks
Input	Programmable selection between DDI clocks
Frequency	PLL output frequency divided by 5
Default after reset	Disabled
Programming	Must be programmed by software when enabling and disabling a display. Programming is done through the TRANS_CLK_SEL registers. See the section on Port Clock Programming.

CD Clock

CD clock refers to the Core Display clock which includes the Core Display 1X Clock (CD clock, CDclk, cdclk, CDCLK) and the Core Display 2X Clock (CD2X clock, cd2xclk, CD2XCLK).

	CD clock
Usage	Clocking for most display engine functions
Input	CDCLK PLL output or reference clock.
Frequency	CDCLK PLL disabled - reference or slow clock divided by 2 CDCLK PLL enabled - Frequencies in table above
Default after reset	Running on the reference clock
Programming	Must be programmed by software when enabling and disabling a display. Programming is done through the CDCLK_CTL and CDCLK_PLL_ENABLE registers.

CD Clock Generation



CD Clock PLL

The CDCLK PLL is the main source for CD clock. A programmable divider inside the PLL controls the PLL frequency. The CD2X Divider after the PLL provides additional dividing to create the CD2X clock used by the display engine. The programmable divider value must be set to account for the reference frequency for in the **DSSM** Reference Frequency field.

When the CDCLK PLL is disabled, the CD clock runs at reference clock divided by 2 to maintain register accessibility. The slow clock (croclk) is used by hardware for some power state transitions.

	CDCLK PLL
Alternate Name	ADPLL or DEPLL
Usage	Source for CD clock
Input	Reference clock
Frequency	Programmable - Frequencies in table below
Default after reset	Disabled
Programming	Must be programmed by software when enabling and disabling a display. May be automatically enabled and disabled by hardware for some power states. Programming is done through the CDCLK_PLL_ENABLE register.

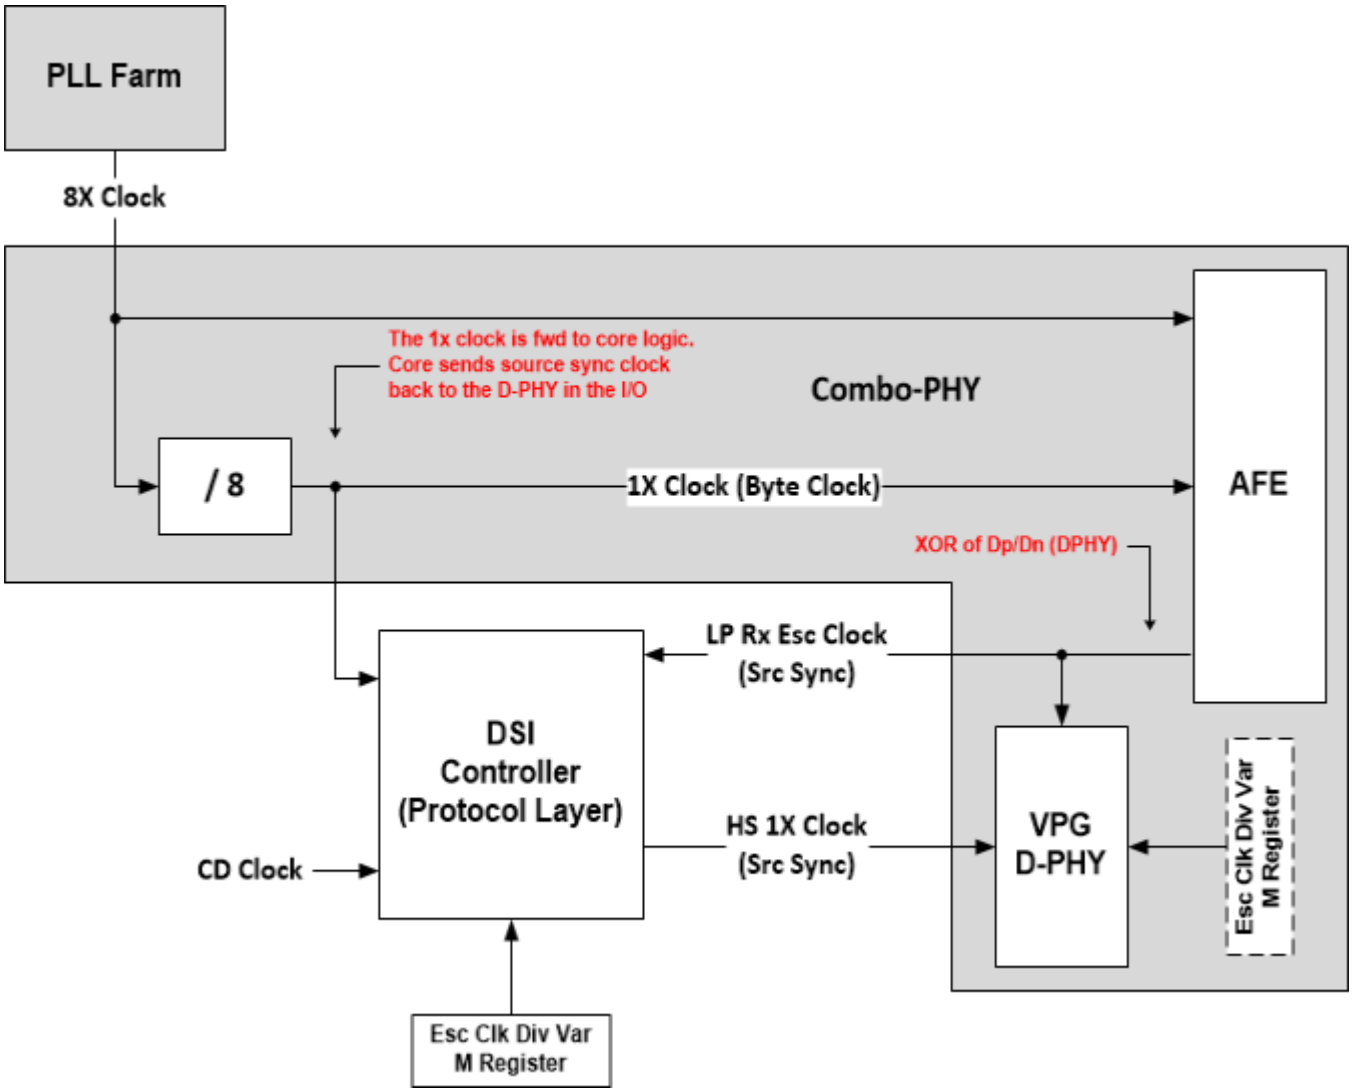
CDCLK PLL Ratio and Divider Programming and Resulting Frequencies

PLL Ratio for 19.2 MHz Reference	PLL Ratio for 38.4 MHz Reference	CD2X Divider	CDCLK MHz
18	9	1	172.8
20	10	1	192
32	16	1	307.2
68	34	2	326.4
58	29	1	556.8
68	34	1	652.8

PLL Ratio for 24 MHz Reference	CD2X Divider	CDCLK MHz
15	1	180
16	1	192
26	1	312
54	2	324
46	1	552
54	1	648

MIPI DSI Clocks

The MIPI DSI clocks are used for the DSI 0 and DSI 1 ports and transcoders.



The DSI port operates within several different clock domains.

- **CD Clock** - The DSI controller receives the Pixel and Software control within this clock domain. The DSI controller clock crosses this information over to the 1X clock domain.
- **8X Clock -** This clock domain is received from the PLL farm and used to transfer the serialized data across the Link (i.e. it is the per-Lane frequency of the DSI Link). Only the I/O block will receive this clock. The IO contains a programmable divider that will divide this clock down to the 1X clock needed by the DSI controller.
- **1X Clock (a.k.a. Byte clock, Word clock)** - This clock domain is used to transfer the HS parallel data (a byte) per Data Lane. Both the DSI Controller and the D-PHY will receive this clock
- **Escape Clock** - This clock is used for LP communication across the DSI Link. Per all MIPI physical layer specifications, this clock has a fixed frequency that should be as close, but not greater than, 20 MHz.
    - **Tx Escape clock** - The Display Engine does not use this clock. Instead it emulates it based off of the DSI_ESC_CLK_DIV register programming and the 1X clock that the Display receives

from the IO. All of the LP Tx signaling from the controller to the DPHY will be driven off of the 1X clock, but will transition at an effective Tx Escape clock frequency.

- **Rx Escape clock** - The IO XOR's together the LP signaling received from the Panel to generate this clock. The IO forwards this clock to the DSI controller

Notes:

1. The MCD block (shaded in grey) delivers a 1X clock to the DSI Controller within the Display Core and to the AFE within the MCD block. The DSI Controller forwards this 1X clock back to the D-PHY within the MCD block along with its data (i.e. the data is source synchronous). The D-PHY will work entirely within the forwarded 1X clock domain. The inlet to the AFE contains a FIFO to handle the phase crossing between the forwarded clock that the D-PHY is operating within and the 1X clock the AFE receives directly from the PLL.
2. The LP Tx Escape clock is derived from a variable M that Software programs within the DSI_ESC_CLK_DIV register. The divider used to live within the IO, so the variable M represents the divisor for generating a clock based off of the 8X clock. Since the divider is within the Display and the clock it is operating on is a 1X clock the divisor becomes "N" which is equal to ceiling(M/8).

	DSI Clocks
Usage	DSI I/O and Transcoder
Input	Programmable selection between the DPLLs
Frequency	PLL clock is the 8X clock. 8X clocks have variable divider to create ~20 MHz escape clocks. Fixed divides for 4X clock and 1X (byte) clocks.
Default after reset	Disabled
Programming	Must be programmed by software when enabling and disabling a display using MIPI DSI.

X^e_D Port Clock Programming

PLL and Clock Usage

This is for mapping the DPCLKA_CFGCR0 bit fields to the PLLs and port names used in display engine.

Note: SKUs with only 2 combo PHY ports should only use DPLL0 and DPLL1.

DPLL0 = PLL available for display combo PHY usage

DPLL1 = PLL available for display combo PHY usage

DPLL2 = TBTPLL, the PLL for thunderbolt

DPLL3 = Not available to display

DPLL4 = PLL available for display combo PHY usage (not available on Y/U SKUs)

DDIA Clock = DDIA and DSI0 (combo port A) symbol clock

DDIB Clock = DDIB and DSI1 (combo port B) symbol clock

DDIC Clock = DDIC (combo port C) symbol clock

TC1 Clock = DDI USBC1 (type C port 1) symbol clock

TC2 Clock = DDI USBC2 (type C port 2) symbol clock

TC3 Clock = DDI USBC3 (type C port 3) symbol clock

TC4 Clock = DDI USBC4 (type C port 4) symbol clock

TC5 Clock = DDI USBC5 (type C port 5) symbol clock

TC6 Clock = DDI USBC6 (type C port 6) symbol clock

TypeC PLL = A PLL in the typeC port, more info in the TypeC PLL Programming section

PLL Frequency Changes

PLL frequency should not be changed while the PLL is enabled.

1. Follow PLL Disable Sequence
2. Follow PLL Enable Sequence using the new frequency

DisplayPort Mode Combo PHY Programming

This programming is for DPLLs when using eDP or DP on combo PHY.

DisplayPort Mode PLL Enable Sequence

1. Enable DPLL power in DPLL_ENABLE.
2. Wait for DPLL power state enabled in DPLL_ENABLE.
    - Should complete immediately.
3. Configure DPLL_SSC to set SSC enable/disable.
4. Configure DPLL_CFGCR0 to set DCO frequency.
5. Configure DPLL_CFGCR1 to set the dividers.
6. Read back DPLL_CFGCR0 or DPLL_CFGCR1, ignoring the data value, this is to ensure writes completed before the next step.
7. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence Before Frequency Change.
8. Enable DPLL in DPLL_ENABLE.
9. Wait for PLL lock status in DPLL_ENABLE.
    - Should complete within 50us.
10. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence After Frequency Change.
11. For each DDI that will use this DPLL
    a. Configure DPCLKA_CFGCR0 to map the DPLL to the DDI.

b. Configure DPCLKA_CFGCR0 to turn on the clock for the DDI. This step and the step before must be done with separate register writes.

DisplayPort Mode PLL Disable Sequence

1. For each DDI that was using this DPLL, configure DPCLKA_CFGCR0 to turn off the clock for the DDI.
2. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence Before Frequency Change.
3. Disable DPLL through DPLL_ENABLE.
4. Wait for PLL not locked status in DPLL_ENABLE.
   - Should complete within 1us.
5. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence After Frequency Change.
6. Disable DPLL power in DPLL_ENABLE.
7. Wait for DPLL power state disabled in DPLL_ENABLE.
   - Should complete immediately.

DisplayPort Mode PLL Values

Link Bit Rate GHz	Reference Clock MHz	DCO Integer	DCO Fraction	Pdiv	Kdiv	Qdiv Mode	Qdiv Ratio
5.4	24	151h	4000h	0010b (3)	001b (1)	0b	00h (1)

Example of DisplayPort on DDIA using HBR 2.7 GHz link rate with SSC and reference 24 MHz

This example assumes DPLL0 is available.

1. Enable DPLL0 power in the DPLL0_ENABLE register
    - Power Enable = 1b (Enable)
2. Wait for DPLL0 power state enabled in DPLL0_ENABLE.
3. Configure DPLL0_SSC register
    - sscen = 1b (Enable)
4. Configure DPLL0 in the DPLL0_CFGCR0 register
    - DCO Fraction = 4000h
    - DCO Integer = 151h
5. Configure DPLL0 in the DPLL0_CFGCR1 register
    - Qdiv Ratio = 00h (1)
    - Qdiv Mode = 0b (Disable)
    - Kdiv = 010b (2)
    - Pdiv = 0010b (3)
6. Read back DPLL0_CFGCR0 or DPLL0_CFGCR1 to ensure writes completed
7. Display Voltage Frequency Switching - Sequence Before Frequency Change
    - Skipped if 270 MHz is low enough to not trigger an increase in the voltage requirement
8. Enable DPLL0 in the DPLL0_ENABLE register
    - PLL Enable = 1b (Enable)
9. Wait for PLL lock status in DPLL0_ENABLE
10. Display Voltage Frequency Switching - Sequence After Frequency Change
    - Skipped if 270 MHz is low enough to not trigger an increase in the voltage requirement

11. Configure DPLL0 mapping to DDIA in the DPCLKA_CFGCR0 register
    - DDIA Clock Select = 00b (DPLL0)
12. Turn on DDIA clock in the DPCLKA_CFGCR0 register
    - DDIA Clock Off = 0b (On)

HDMI Mode Combo PHY Programming

This programming is for DPLLs when using HDMI or DVI on combo PHY.

HDMI Mode PLL Enable Sequence

Sequence is the same as for DisplayPort, except SSC must be disabled.

HDMI Mode PLL Disable Sequence

Sequence is the same as for DisplayPort

Formula for HDMI Mode DPLL Programming

Reference frequency = 38.4, 24, or 19.2 MHz (Register DSSM Reference Frequency indicates the frequency). If reference frequency is 38.4, use 19.2 because the DPLL automatically divides that by 2.

Symbol clock frequency MHz = DCO Frequency / (Pdiv * Qdiv * Kdiv) / 5.

AFE clock = PLL output frequency = Symbol clock frequency MHz * 5 = DCO Frequency / (Pdiv * Qdiv * Kdiv).

Pdiv can be 2, 3, 5, or 7.

Kdiv can be 1, 2, or 3.

If Kdiv != 2, then Qdiv must be 1. Else Qdiv can be 1 to 255.

Minimum DCO frequency = 7,998 MHz

Maximum DCO frequency = 10,000 MHz

Midpoint DCO frequency = 8,999 MHz

Note: If the desired symbol clock frequency cannot be achieved with the valid values of P, Q, K, and DCO frequencies, use a different screen resolution with a different symbol clock frequency.

Note: HDMI symbol clock frequency can be different from the pixel rate.

HDMI Color Format	Bits per color	HDMI Symbol Clock	HDMI Pixel Rate
RGB or YUV444	8	1 * pixel rate	1 * symbol clock
RGB or YUV444	10	5/4 * pixel rate	4/5 * symbol clock
RGB or YUV444	12	3/2 * pixel rate	2/3 * symbol clock
YUV420	8	1/2 * pixel rate	2 * symbol clock
YUV420	10	5/8 * pixel rate	8/5 * symbol clock
YUV420	12	3/4 * pixel rate	4/3 * symbol clock

Algorithm to Find HDMI Mode DPLL Programming

1. Calculate AFE clock
2. For each legal divider (P*Q*K), find the DCO.
3. Select the divider that gives the DCO closest to the midpoint and fits within the minimum or maximum.
4. Find the P, Q, K values to create that divider.

Calculating Frequency from Divider Values

Symbol clock frequency in MHz = DCO divider * Reference Frequency in MHz / (5 * Pdiv * Qdiv * Kdiv)

DCO divider from DPLL_CFGCR0 DCO Integer + (DPLL_CFGCR0 DCO Fraction / 2^15)

Pdiv from DPLL_CFGCR1 Pdiv

Qdiv from DPLL_CFGCR1 Qdiv Mode ? DPLL_CFGCR1 Qdiv Ratio : 1

Kdiv from DPLL_CFGCR1 Kdiv

Example of DVI on DDIB using 113.309 MHz symbol clock and reference 24 MHz

This example assumes DPLL1 is available.

Frequency programming algorithm finds Pdiv=2, Qdiv=4, Kdiv=2, DCO Frequency = 9064.72

DCO Integer = INT(9064.72/24) = 377

DCO Fraction = INT(((9064.72/24) - DCO Integer) * 2^15) = 22,828

1. Enable DPLL1 power in the DPLL1_ENABLE register
    - Power Enable = 1b (Enable)
2. Wait for PLL power state enabled in DPLL1_ENABLE.
3. Configure DPLL1_SSC register
    - sscen = 0b (Disable)
4. Configure DPLL1 in the DPLL1_CFGCR0 register
    - DCO Fraction = 592Ch (22828)
    - DCO Integer = 179h (377)
5. Configure DPLL1 in the DPLL1_CFGCR1 register
    - Qdiv Ratio = 04h (4)
    - Qdiv Mode = 1b (Enable)
    - Kdiv = 010b (2)
    - Pdiv = 0001b (2)
6. Read back DPLL1_CFGCR0 or DPLL1_CFGCR1 to ensure writes completed
7. Display Voltage Frequency Switching - Sequence Before Frequency Change
    - Skipped if 113.309 MHz is low enough to not trigger an increase in the voltage requirement
8. Enable DPLL1 in the DPLL1_ENABLE register
    - PLL Enable = 1b (Enable)
9. Wait for PLL lock in DPLL1_ENABLE
10. Display Voltage Frequency Switching - Sequence After Frequency Change
    - Skipped if 113.309 MHz is low enough to not trigger an increase in the voltage requirement
11. Configure DPLL1 mapping to DDIB in the DPCLKA_CFGCR0 register
    - DDIB Clock Select = 01b (DPLL1)
12. Turn on DDIB clock in the DPCLKA_CFGCR0 register
    - DDIB Clock Off = 0b (On)

MIPI DSI DPLL Programming

This programming is for DPLLs when using MIPI DSI.

Note that if the Driver wishes to maintain a single enabling sequence between DP/eDP and MIPI DSI, then the same enabling sequence defined for DP/eDP on combo PHY can be used for MIPI DSI. The only difference between the two sequences is:

1. The order of the DPLL mapping (DPCLKA_CFGCR0) with respect to the DPLL_ENABLE. The order of these two steps is unimportant
2. The programming of the *_ESC_CLK_DIV registers. The placement of the *_ESC_CLK_DIV registers can be placed anywhere within the sequence (i.e. at the beginning or end of the sequence) to facilitate a single function.

MIPI DSI DPLL Enable Sequence

1. Enable DPLL power in DPLL_ENABLE.
2. Wait for DPLL power state enabled in DPLL_ENABLE.
    - Should complete immediately.
3. Configure DPLL_SSC to set SSC enable/disable.
4. Configure DPLL_CFGCR0 to set DCO frequency.
5. Configure DPLL_CFGCR1 to set the dividers.
6. Read back DPLL_CFGCR0 or DPLL_CFGCR1, ignoring the data value, this is to ensure writes completed before the next step.
7. Configure DPCLKA_CFGCR0 to map the DPLL to the DDI/DSI.
    - Do not turn on the clock for the DDI. DSI has independent clock gating controlled by MIPI DSI mode programming.
8. Read back DPCLKA_CFGCR0, ignoring the data value, this is to ensure write completed before the next step.
9. Configure both **DSI_ESC_CLK_DIV** and **DPHY_ESC_CLK_DIV** registers. Both registers must be programmed with the same value.
10.
11. Read back both DPHY_ESC_CLK_DIV, ignoring the data value, this is to ensure write completed before the next step.
12. Enable DPLL in DPLL_ENABLE.
13. Wait for PLL lock status in DPLL_ENABLE.
    - Should complete within 50us.

MIPI DSI DPLL Disable Sequence

Sequence is the same as for DisplayPort, except there is not need to configure DPCLKA_CFGCR0 to turn off the clock for the DDI.

Formula for MIPI DSI DPLL Programming

Follow the same formula as for HDMI Mode. The AFE clock is the MIPI 8X clock.

Formula for MIPI DSI Escape Clock Programming

The MIPI DSI port operates with a constant frequency clock referred to as the Escape clock. The Escape clock should be programmed to be as close to, but not greater than 20 MHz. The Escape clock frequency will be determined by dividing the 8X frequency by a variable "M".

$f_{esc} = f_{8x} / M <= 20$ MHz

Solving for M supplies the programming necessary for the DSI_ESC_CLK_DIV and DPHY_ESC_CLK_DIV registers.

Escape clock divider M = ceiling(f_{8x} (MHz) / 20 MHz)

Example for DSI0 8X 566.545 and reference 24 MHz

This example assumes DPLL0 is available.

8x clock = AFE Clock = 566.545 MHz

Frequency programming algorithm finds Pdiv=3, Qdiv=1, Kdiv=1, DCO Frequency = 8498.175

Escape clock divider M = ceiling(566.545 / 20 MHz) = 29

DCO Integer = INT(8498.175/24) = 354

DCO Fraction = INT(((8498.175/24) - DCO Integer) * 2^15) = 2969

1. Enable DPLL0 power in the DPLL0_ENABLE register
    - Power Enable = 1b (Enable)
2. Wait for PLL power state enabled in DPLL0_ENABLE.
3. Configure DPLL0_SSC register
    - sscen = 0b (Disable)
4. Configure DPLL0 in the DPLL0_CFGCR0 register
    - DCO Fraction = 0B99h (2969)
    - DCO Integer = 162h (354)
5. Configure DPLL0 in the DPLL0_CFGCR1 register
    - Qdiv Ratio = 00h (1)
    - Qdiv Mode = 0b (Disable)
    - Kdiv = 001b (1)
    - Pdiv = 0010b (3)
6. Read back DPLL0_CFGCR0 or DPLL0_CFGCR1 to ensure writes completed
7. Configure DPCLKA_CFGCR0 DPLL0 mapping to DSI0 in the DPCLKA_CFGCR0 register
    - DDIA (DSI0) Clock Select = 00b (DPLL0)
8. Turn on DSI0 clock in the DPCLKA_CFGCR0 register
    - DDIA (DSI0) Clock Off = 0b (On)
9. Read back DPCLKA_CFGCR0 to ensure write completed

10. Configure MIPI escape clock dividers in DSI_ESC_CLK_DIV_0 and DPHY_ESC_CLK_DIV_0
    - Escape Clock Divider M = 0x01D (Divide by 29)
11. Read back DPHY_ESC_CLK_DIV to ensure write completed
12. Enable DPLL0 in the DPLL0_ENABLE register
    - PLL Enable = 1b (Enable)
13. Wait for PLL lock in DPLL0_ENABLE

Thunderbolt PLL Programming

This programming is for ports going to Thunderbolt. Those ports use the TBT PLL (a version of DPLL) shared across all thunderbolt ports. Thunderbolt supports a few fixed frequencies which are all produced simultaneously from parallel dividers after the PLL.

Thunderbolt PLL Enable Sequence

1. Enable PLL power in TBT_PLL_ENABLE (an instance of the DPLL_ENABLE register).
2. Wait for PLL power state enabled in TBT_PLL_ENABLE.
    - Should complete immediately.
3. Configure TBTPLL_CFGCR0 to set DCO frequency.
4. Read back TBTPLL_CFGCR0, ignoring the data value, this is to ensure writes completed before the next step.
5. Enable PLL in TBT_PLL_ENABLE.
6. Wait for PLL lock status in TBT_PLL_ENABLE.
    - Should complete within 50us.
7. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence Before Frequency Change.
    - Since the PLL produces multiple frequencies simultaneously, use the frequency selected for the port when determining the voltage requirement.
8. For each port that will use this PLL, program DDI_CLK_SEL to map the TBT clock to the port.
9. For each port that will use this PLL, configure DPCLKA_CFGCR0 to turn on the clock for the port.
10. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence After Frequency Change.
    - Since the PLL produces multiple frequencies simultaneously, use the frequency selected for the port when determining the voltage requirement.

Thunderbolt PLL Disable Sequence

- Since multiple ports can share the same PLL, the PLL is not disabled until after all the ports using it have turned off the clock.

1. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence Before Frequency Change.

2. For each port that was using this PLL, configure DPCLKA_CFGCR0 to turn off the clock for the port.
3. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence After Frequency Change.
4. Disable PLL through TBT_PLL_ENABLE.
5. Wait for PLL not locked status in TBT_PLL_ENABLE.
    - Should complete within 1us.
6. Disable DPLL power in TBT_PLL_ENABLE.
7. Wait for DPLL power state disabled in TBT_PLL_ENABLE.
    - Should complete immediately.

Thunderbolt PLL Divider Values

The thunderbolt PLL must always be configured to give a 1620 MHz output, depending on reference clock, using the values below.

Reference Clock	Pdiv	Kdiv	Qdiv	DCO MHz	DCO divided by Reference Clock MHz	DCO Integer hex	DCO Fraction hex
19.2 or 38.4 MHz	Not used	Not used	Not used	1620	84.375	0x54	0x3000
24 MHz	Not used	Not used	Not used	1620	67.5	0x43	0x4000

Thunderbolt Port Frequency Selection

Hardcoded dividers on the PLL 1620 MHz output produce 162, 270, 540, and 810 MHz symbol clock frequencies. The DDI_CLK_SEL register allows each port to select between those 4 frequencies.

Example of Thunderbolt on TC1 using 270 MHz symbol clock

This example assumes the reference frequency is 24 MHz.

1. Enable TBT_PLL power in the TBT_PLL_ENABLE register
    - Power Enable = 1b (Enable)
2. Wait for PLL power state enabled in TBT_PLL_ENABLE.
3. Configure TBTPLL_CFGCR0 register
    - DCO Fraction = 4000h
    - DCO Integer = 43h
4. Read back TBTPLL_CFGCR0 to ensure writes completed
5. Enable PLL in the TBT_PLL_ENABLE register
    - PLL Enable = 1b (Enable)
6. Wait for PLL lock in TBT_PLL_ENABLE
7. Display Voltage Frequency Switching - Sequence Before Frequency Change
    - Skipped if 270 MHz is low enough to not trigger an increase in the voltage requirement
8. Configure TC1 to use TBT 270 MHz in DDI_CLK_SEL_C register

- Clock Select = 1101b (TBT 270)

9. Configure DPCLKA_CFGCR0 to turn on TC1 clock
    - TC1 Clock Off = 0b (On)
10. Display Voltage Frequency Switching - Sequence After Frequency Change
    - Skipped if 270 MHz is low enough to not trigger an increase in the voltage requirement

TypeC PHY PLL Programming for Displayport

NOTE: Display uses PLL1, not PLL0. The defaults of associated registers may be different.

TypeC PHY and PLL registers need to be accessed as per the instructions in Dekel PHY Access page.

Register programming for DP frequencies consists of 2 parts: rate independent programming and rate dependent programming.

DKL PLL Enable Sequence

1. Enable PLL power in MGPLL_ENABLE (an instance of the DPLL_ENABLE register).
2. Wait for PLL power state enabled in MGPLL_ENABLE.
    - Should complete within 10us.
3. Program PLL registers as given in tables below - rate independent first and then rate dependent.
4. Read back the last programmed PHY PLL register, ignoring the data value, to ensure writes completed before the next step.
5. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence Before Frequency Change.
6. Enable PLL in MGPLL_ENABLE.
7. Wait for PLL lock status in MGPLL_ENABLE.
    - Timeout and fail after **900**us.
8. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence After Frequency Change.
9. Program DDI_CLK_SEL to map the Type-C PLL clock to the port.
10. Configure DPCLKA_CFGCR0 to turn on the clock for the port.

DKL PLL Disable Sequence

1. Configure DPCLKA_CFGCR0 to turn off the clock for the port.
2. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence Before Frequency Change.
3. Disable PLL through MGPLL_ENABLE.
    - Should complete within 50us.
4. Wait for PLL not locked status in MGPLL_ENABLE.

5. If the frequency will result in a change to the voltage requirement, follow the Display Voltage Frequency Switching - Sequence After Frequency Change.
6. Disable PLL power in MGPLL_ENABLE.
7. Wait for PLL power state disabled in MGPLL_ENABLE.
    - Should complete immediately.

The following DP rate independent and rate dependent programming must check DFLEXDPSP[12] for IOM FW support.

MFD DP - Rate independent programming - 100 MHz reference clock

This table covers programming for cases where DisplayPort is sharing lanes with USB.

TypeC PHY PLL Programming - algorthmic steps

NOTE: Display uses PLL1, not PLL0. The defaults of associated registers may be different.

If the desired symbol clock frequency cannot be achieved with the valid programming, use a different screen resolution with a different symbol clock frequency.

The following algorithmic steps apply for HDMI protocol and enumerated reference clocks. For DP protocol, refer to the tables above.

```
 $symbol_frequency = Desired HDMI symbol clock frequency in MHz(example: 594 MHz for HDMI 2.0
4K 60 Hz)
 $refclk_mhz = Reference frequency (19.2 MHz or 24.0 MHz or 38.4 MHz)
 $ssc_en = SSC enable  // DO NOT SELECT SSC $dp = 1 for DisplayPort, 0 for HDMI // DO NOT
SELECT DISPLAYPORT OPTION Set $dp = 0
 $dp_dco = 8.1;
 $dco_min_freq = $dp ? $dp_dco : $ssc_en ? 8 : 7.992;
 $dco_max_freq = $dp ? $dp_dco : 10;
 @div1_vals = ( 7, 5, 3, 2);
 @div2_vals = ( 10, 9, 8, 7, 6, 5, 4, 3, 2, 1 );
 $success = 0;

 $frequency = $symbol_frequency/100;

 for $div1 (@div1_vals) {
     for $div2 (@div2_vals) {
         $dco = $div1 * $div2 * $frequency / 2;
         if ( $dco >= $dco_min_freq and $dco <= $dco_max_freq ) {
           Program DKL_REFCLKIN_CTL od_refclkin2_refclkmux_2_0 = 1
           Program DKL_CLKTOP2_HSCLKCTL od_clktop2_coreclk_inputsel = 1
```

```
            Program DKL_CLKTOP2_CORECLKCTL1 od_clktop2_coreclka_divratio = 5

            if ($div2 >= 2) {
              Program DKL_CLKTOP2_HSCLKCTL od_clktop_tlinedrv_clksel_1_0 = 1
            } else {
              Program DKL_CLKTOP2_HSCLKCTL od_clktop_tlinedrv_clksel_1_0 = 0
            }
            Program DKL_CLKTOP2_HSCLKCTL od_clktop_coreclk_inputsel = $dp ? 0b : 1b

Display Voltage Frequency Switching

Display Voltage and Frequency Switching (DVFS) is used to adjust the display voltage to match the display clock frequencies. If voltage is set too low, it will break functionality. If voltage is set too high, it will waste power. The voltage rail for display is shared by the entire system agent, so it has a large power impact.

When changing clock frequencies, graphics software must inform the power controller of the display voltage requirement. The power controller tracks requests from all users of the voltage rail and sets voltage to accommodate all the requests. The voltage requirements are separated into discrete levels aligned to the frequencies of several clocks used by display.

Voltage Requirement Selection

The voltage requirement is specified by selecting from several discrete voltage levels. The power controller will map these levels to the actual voltage values, which are usually determined on a part by part basis during manufacturing.

Only the CD clock and DDI clocks (max of all DDI clocks) are used to select the voltage levels. Other display clocks are either supported at all frequencies with the minimum voltage, or have their voltage requirements accounted for by non-graphics software.

Voltage Level	CD clock MHz	Max DDI symbol clock MHz	Comment
0	307.2, 312, or lower	<=594	No 5k or 8k
1	324 or 326.4	<=594	These display clocks are mainly for resolutions under 5k with multiple displays enabled (cdclk PLL divided by 2 to allow for smooth increase to max cdclk)
2	556.8 or 552	>594	These display clocks are mainly for non-HDR 5K and 8k, or some cases with DP multistream or USB TypeC
3	652.8 or 648	>594	These display clocks are mainly for HDR 5k and 8k

If CD clock <= 312 MHz AND Max of DDI clocks <= 594 MHz, use level 0.

Else If CD clock <= 326.4 MHz AND Max of DDI clocks <= 594 MHz, use level 1.

Else If CD clock <= 556.8 AND Max of DDI clocks > 594 MHz, use level 2.

Else, use level 3.

Note: For these calculations, disabling a clock is the same as switching it to the lowest frequency.

The sequences below are used when changing CD clock frequency and when changing DDI clock frequency during a mode set.

The following sequences are not used on their own. They are called as part of other sequences which change the display clock frequencies.

Sequence Before Frequency Change

- This sequence requests the power controller to raise voltage to the maximum

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data Low = 0x00000003.
3. Write GT Driver Mailbox Data High = 0x00000000.
4. Write GT Driver Mailbox Interface = 0x80000007.
5. Poll GT Driver Mailbox Interface for Run/Busy indication cleared (bit 31 = 0).
    - Timeout after 150 us. Do not change CD clock frequency if there is a timeout.
6. Read GT Driver Mailbox Data Low, if bit 0 is 0x1, continue, else go to step 2.
    - If the condition in step 6 is not satisfied after cycling through steps 2-6 for 3 ms (typically <200 us), timeout and fail and do not change clock frequency.

Sequence After Frequency Change

- This sequence requests the power controller to set the voltage to the selected level. The power controller may choose to keep the voltage higher to accommodate other users outside of display.

1. Write GT Driver Mailbox Data Low with the voltage level selection, following the table above.
    - For Level 0, write 0x00000000.
    - For Level 1, write 0x00000001.
    - For Level 2, write 0x00000002.
    - For Level 3, write 0x00000003.
2. Write GT Driver Mailbox Data High = 0x00000000.
3. Write GT Driver Mailbox Interface = 0x80000007.
    - There is no need for display software to wait for the voltage to adjust.

Sequences for Changing CD Clock Frequency

Restrictions
The CD clock frequency impacts the maximum supported pixel rate and display watermark programming.
The CD clock frequency must be at least twice the frequency of the Azalia BCLK.

Sequence for Changing CD Clock Frequency

1. Unless changing only the CD2X Divider, disable all display engine functions using the full mode set disable sequence on all pipes, ports, and planes.
    - Includes Global Time Code
    - Display power wells may be left enabled
2. Follow the Display Voltage Frequency Switching - Sequence Before Frequency Change

3. Enable or change the frequency of CD clock
    a. If enabling CDCLK PLL
        i. Write CDCLK_PLL_ENABLE with the PLL ratio, but not yet enabling it.
        ii. Set CDCLK_PLL_ENABLE PLL Enable
        iii. Poll CDCLK_PLL_ENABLE for PLL lock
        iv. Timeout and fail if not locked after 200 us
        v. Write CDCLK_CTL with the CD2X Divider selection and CD Frequency Decimal value to match the desired CD clock frequency
    b. If disabling CDCLK PLL
        i. Clear CDCLK_PLL_ENABLE PLL Enable
        ii. Poll CDCLK_PLL_ENABLE for PLL unlocked
        iii. Timeout and fail if not unlocked after 200 us
    c. If changing the CDCLK PLL frequency
        i. Follow steps above for disabling CDCLK PLL.
        ii. Follow steps above for enabling CDCLK PLL, using the new PLL ratio.
    d. If changing only the CD2X Divider
        i. Write CDCLK_CTL with the CD2X Pipe selection, CD2X Divider selection, and CD Frequency Decimal value to match the desired CD clock frequency
        ii. If pipe is enabled, wait for start of vertical blank for change to take effect
4. Follow the Display Voltage Frequency Switching - Sequence After Frequency Change
5. Update programming of functions that use the CD clock frequency

If these features are not currently enabled, the programming can be delayed to when they are enabled.

- Wireless Display 27 MHz frequency in the WD_27_M and WD_27_N registers.
    - For CD clock 168 MHz, program M=9 and N=56 (decimal).
    - For CD clock 336 MHz, program M=9 and N=112 (decimal).
    - For CD clock 528 MHz, program M=9 and N=176 (decimal).
    - For CD clock 172.8 MHz, program M=45 and N=288 (decimal).
    - For CD clock 307.2 MHz, program M=45 and N=512 (decimal).
    - For CD clock 556.8 MHz, program M=45 and N=928 (decimal).
    - For CD clock 652.8 MHz, program M=45 and N=1088 (decimal).
    - For CD clock 180 MHz, program M=45 and N=300 (decimal).
    - For CD clock 312 MHz, program M=45 and N=520 (decimal).
    - For CD clock 552 MHz, program M=45 and N=920 (decimal).
    - For CD clock 648 MHz, program M=45 and N=1080 (decimal).
- Utility pin backlight frequency and duty cycle in the BLC_PWM_DATA register.

Resets

The north and south display engines are reset by PCI Function Level Resets (FLR) and the chip level resets.

The south display engine runs panel power down sequencing (if configured to do so by NDE_RSTWRN_OPT) before resetting.

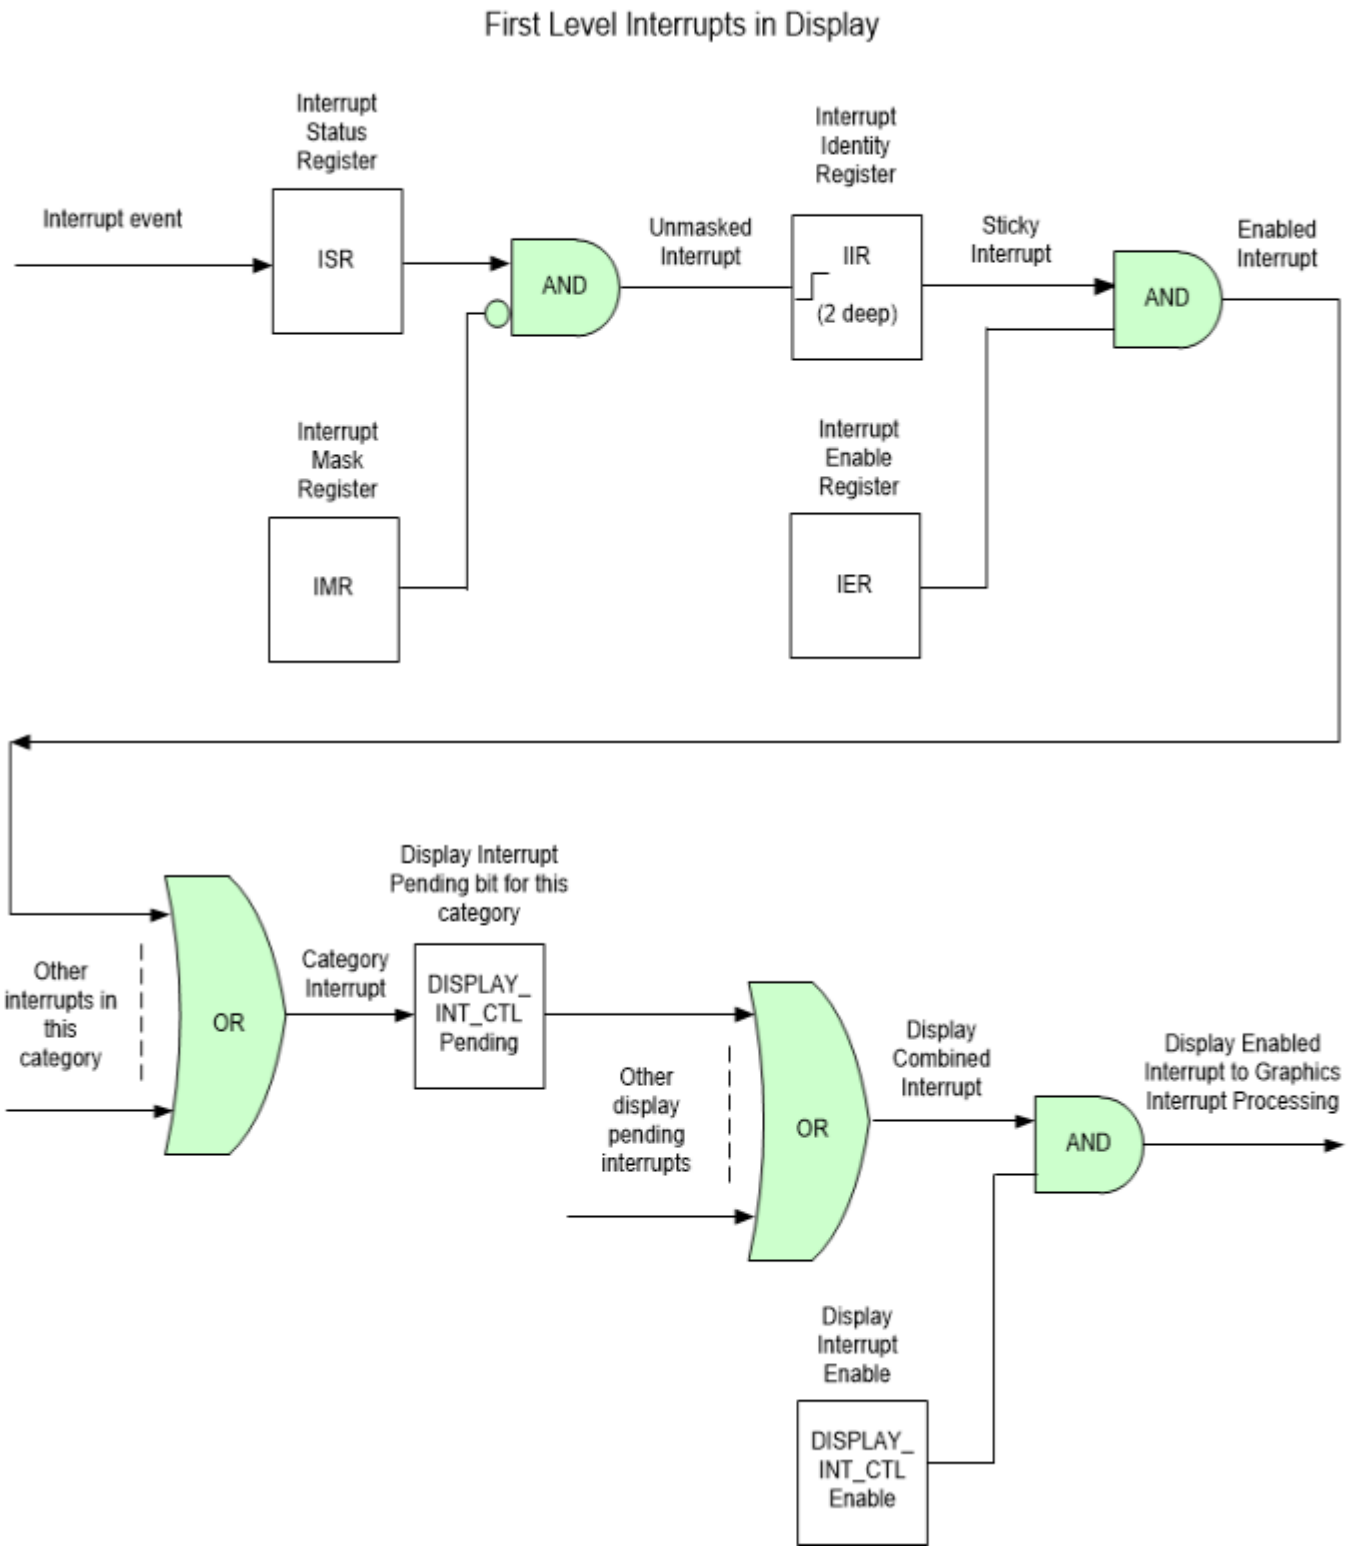
DE HPD Interrupt Definition
Graphics Primary Interrupt
Graphics Interrupt Introduction

Interrupt Flow



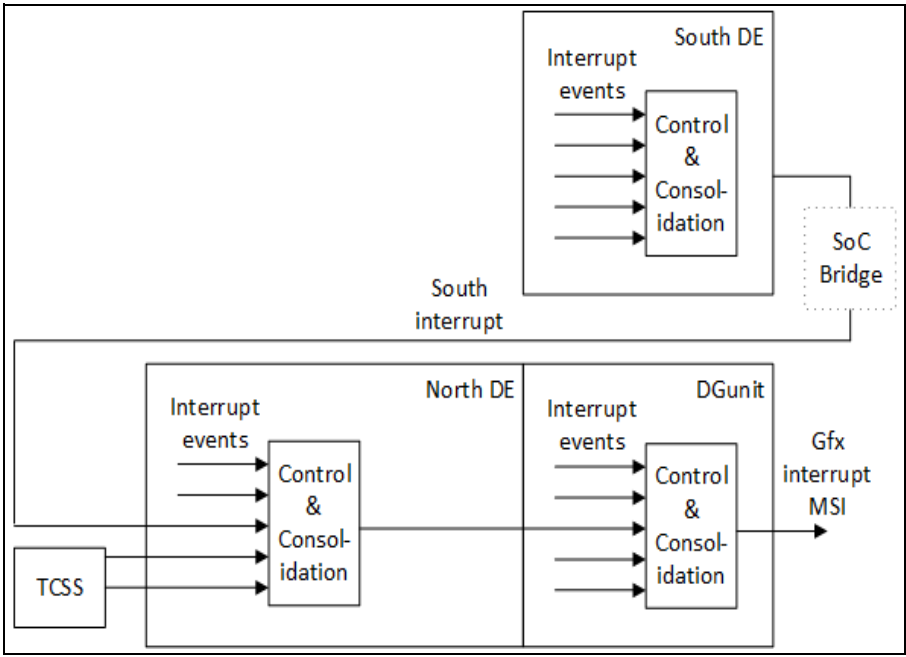
1. For every first level interrupt bit
    a. The interrupt event comes in to the interrupt handling logic.
        - There may be more levels of interrupt handling behind each event. For example, the PCH Display interrupt event is the result of the SDE interrupt registers.
    b. The interrupt event goes to the Interrupt Status Register (ISR) where live status can be read back.
        - The live status is mainly useful for hotplug interrupts where it gives the live state of the hotplug line.
        - The live status is not useful for pulse interrupt events due to the short period that the status will be present.
    c. The interrupt event is ANDed with the inverted Interrupt Mask Register (IMR) to create the unmasked interrupt.
    d. The unmasked interrupt rising edge sets the sticky bit in the Interrupt Identity Register (IIR).
        - The IIR can be cleared by writing a 1 to it.
        - The IIR can queue up to two interrupt events. When the IIR is cleared, it will set itself again if a second event was stored.
    e. The sticky interrupt is ANDed with the Interrupt Enable Register (IER) to create the enabled interrupt.
2. All enabled interrupts are then ORed by category (Pipe, Audio, etc.) to create a category interrupt which is then visible in one of the Display Interrupt Control Register (DISPLAY_INT_CTL) pending category bits.
3. All pending interrupts are then ORed to create the display combined interrupt.
4. The display combined interrupt is ANDed with the Display Interrupt Enable (DISPLAY_INT_CTL Bit 31) to create the display enabled interrupt.
5. The display enabled interrupt then goes to graphics interrupt processing before eventually creating an interrupt message which will reach the OS.

Interrupt Service Routine

1. Read graphics primary interrupt register to find a display interrupt pending.
2. Write graphics primary interrupt register to clear display interrupt.
3. Disable Display Interrupt Control (can be done here, or anywhere before the final step)
    - Clear bit 31 of DISPLAY_INT_CTL.
    - This de-asserts the display enabled interrupt and is required in order for the final step to cause a new assertion when all interrupts are not cleared during the service routine.
4. Find the category of interrupt that is pending
    - Read DISPLAY_INT_CTL and record which interrupt pending category bits are set.
5. Find the source(s) of the interrupt and clear the Interrupt Identity bits (IIR)
    - Read the IIR associated with each pending interrupt category, record which bits are set, then write back 1s to clear the bits that are set.

- There can be up to 2 interrupts recorded per source, requiring multiple writes to the IIR to fully clear.

6. Process the interrupt(s) that had bits set in the IIRs.
7. Optionally go to step 4 again to check for any new display interrupts that have happened during previous steps
    - This is optional since any new interrupts will also be found when they trigger the interrupt service routine again after the final step and then re-enter from the start of the routine.
8. Re-enable Display Interrupt Control
    - Set bit 31 of DISPLAY_INT_CTL.
    - If interrupts were not fully cleared before this point, then the display enabled interrupt will re-assert and there will be a new display interrupt in graphics primary interrupt register.



South display interrupt routed to north display.

North display connected to DGunit.

MBus

Mbus is an internal ring type bus. Display high priority clients reside on this bus. The introduction of a ring architecture allow for easy addition/deletion of clients as well as improves Bandwidth. The various "boxes" are different types of tap points where display clients are plugged in.

MBus
MBUS_ABOX_CTL
MBUS_BBOX_CTL
MBUS_DBOX_CTL
MBUS_UBOX_CTL

MBus programming during display Initialization

Program credits in MBUS_ABOX_CTL, MBUS_ABOX1_CTL, MBUS_ABOX2_CTL

The MBus credits should be setup once with the following default values during the display initialization.

MBUS_ABOX_CTL for this pipe -> BT Credits Pool1 = 16

MBUS_ABOX_CTL for this pipe -> BT Credits Pool2 = 16

MBUS_ABOX_CTL for this pipe -> B Credits = 1

MBUS_ABOX_CTL for this pipe -> BW Credits = 1

DBUF_CTL for this pipe -> Tracker State Service = 8

The following programming must be done when enabling each pipe as a part of *configure other pipe settings* in the *Enable Planes, Pipe, and Transcoders* sequence.

MBUS_DBOX_CTL for this pipe -> A Credits = 2

MBUS_DBOX_CTL for this pipe -> BW Credits = 2

MBUS_DBOX_CTL for this pipe -> B Credits = 12

Render Response

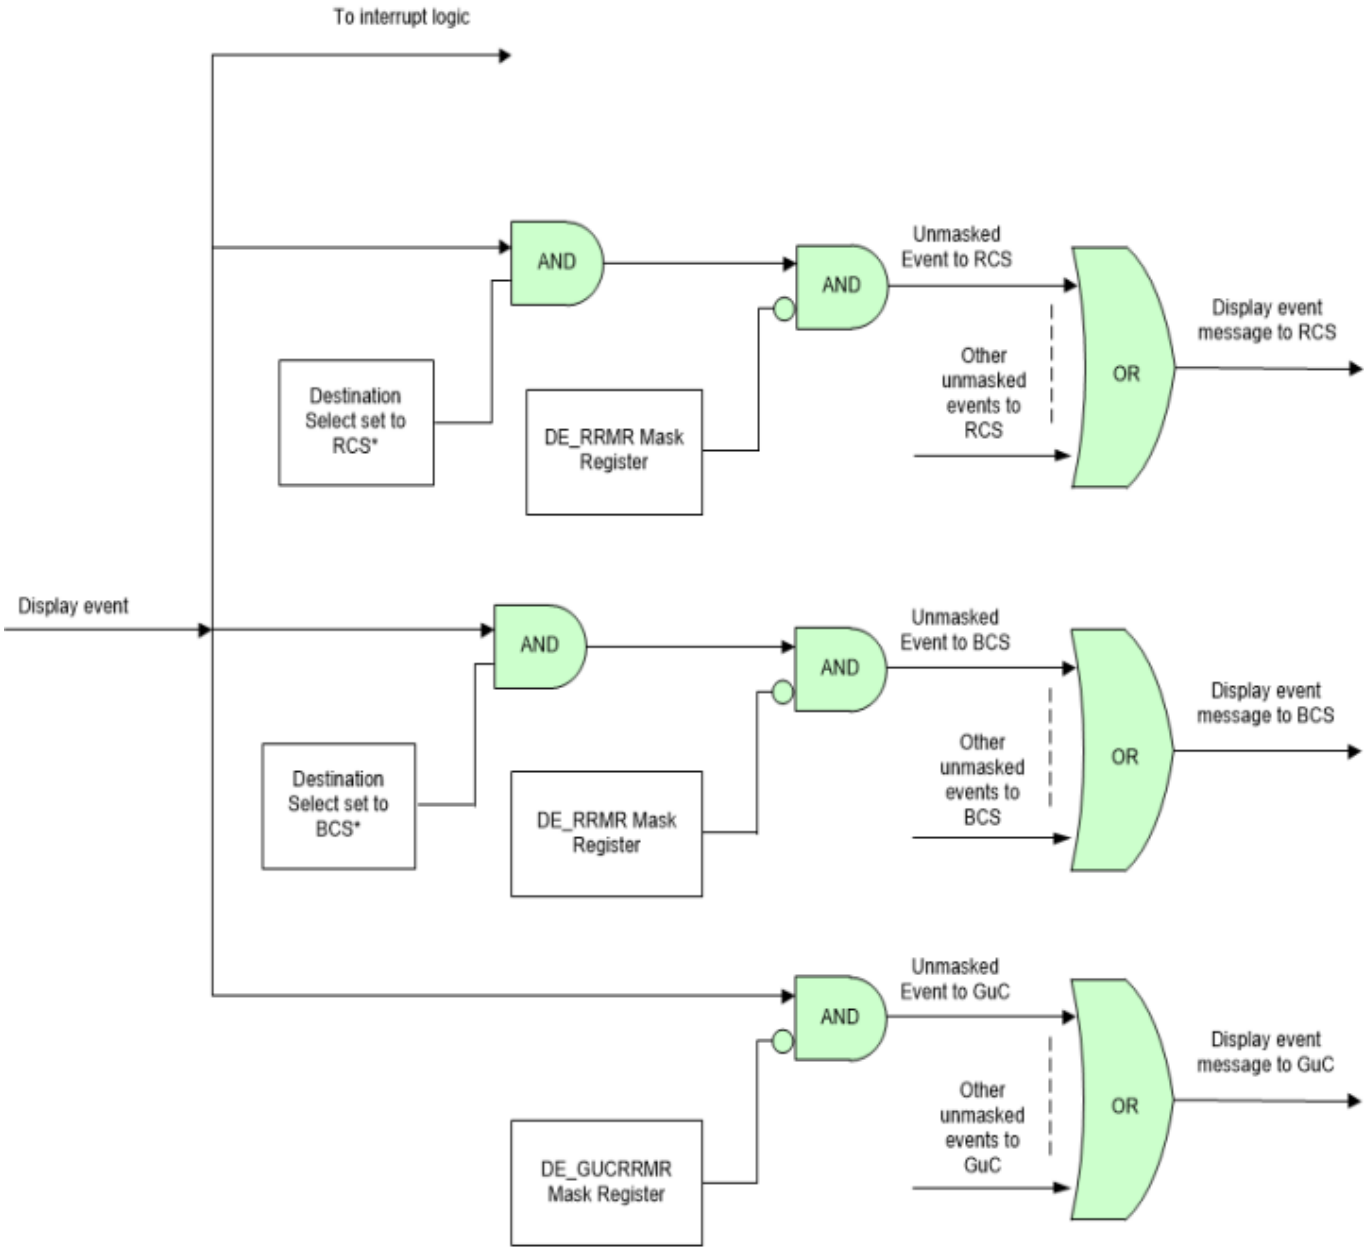
Display Engine Render Response Message Definition

DE_RRMR

DE_RRMR_DW1

DE_RRMR_DW2

DE_RR_DEST



*For Vblank events, destination select is configured in DE_RR_DEST to direct the event to RCS, BCS, or both at once.
For MMIO triggered flip done events, destination select is configured in PLANE_SURF Ring Flip Source to direct the event to either RCS or BCS.
For ring (AKA message) triggered flip done events, destination select is configured automatically by decoding whether the flip came from BCS or RCS.

GuC supports some additional events beyond what RCS and BCS support. In that case the event can feed into the GuC masking directly without branching to RCS and BCS.

Older documentation refers to RCS as CS.

Hot Plug Detection

This topic describes hot plug detection for type C ports with DP alternate mode or DP over thunderbolt. Hotplug detection for non-typeC is done through the south display.

Type C Port Hot Plug Detection

HOTPLUG_CTL

These registers are used for detecting hot plug on thunderbolt or type C (DP alternate). They will generate interrupts in DE_HPD_INTERRUPT. HOTPLUG_CTL has the status bits to indicate if long or short pulses are detected. Do not use the interrupt ISR for finding the live connect state. It can become out of sync with the typeC sub-system after some power states and resets. Instead, use DFLEXDPSP TC Live State fields.

The south display hot plug detection registers are used for detecting hot plug for combo PHY ports and type C ports with non-type C connectors (legacy or static configuration).

HPD Interrupt Sequence

- This sequence is for identifying each type of hotplug. Follow interrupt documentation for how interrupt service routine should enable, disable, and clear interrupts.

1. Display interrupt received and DISPLAY_INT_CTL shows source of the interrupt is DE HPD Interrupts pending (north display HPD)
2. Read DE_HPD_INTERRUPT IIR to find if source port type is thunderbolt or typeC (DP alternate)
3. Read <port type, TBT for thunderbolt, TC for DP alternate>_HOTPLUG_CTL to find the HPD Status
    - Long pulse, short pulse, both, or none
4. If long pulse or both
    1. Read PORT_TX_DFLEXDPSP TC Live State to find the live state
        - Long pulse with live state = 1 indicates a connect
        - Long pulse with live state = 0 indicates a disconnect
    2. Follow the TypeC Programming connect flow or disconnect flow
5. If short pulse and not HDMI
    1. Query the panel and then proceed as required by panel

Resets and Power States

Hotplug interrupts can be missed around resets and power states. When coming out of any state where HPD interrupts can be missed (cold boot, warm reset, S3/S4, DC9, Function Level Reset, handoff between VBIOS/GOP/EFI and driver, etc.) use the following sequence to enable HPD interrupts and find if any previous HPD was missed and needs to be serviced.

1. Enable HOTPLUG_CTL and configure interrupt related registers so that HPD interrupts will be received.

2. If HPD interrupt received after step 1, handle it as usual and abort the remaining steps for that port.
3. Process live state for each typeC port.
    - Read PORT_TX_DFLEXDPPMS DPPMSTC, PORT_TX_DFLEXDPCSSS DPPMSTC, and PORT_TX_DFLEXDPSP TC Live State.
    - Process connect or disconnect as per truth table, abort if HPD interrupt is received for this port and handle the disconnect/connect requested by the HPD.

The table below illustrates the next steps based on the live state and connection state.

DPSP TC Live State	DPPMS DPPMSTC	DPCSSS DPPMSTC	IOM State	Software Next Steps
00	0	0	Disconnect complete	Do nothing right now. IOM will send HPD if something is needed.
00	1	0	IOM action pending	Do nothing right now. IOM will send HPD if something is needed.
01	1	0	DP-alt connect pending	Follow connect flow for DP alternate.
01	1	1	DP-alt connect complete	Follow connect flow for DP alternate from the step after DPCSSS DPPMSTC is set to 1.
00	1	1	DP-alt disconnect pending	Follow disconnect flow for DP alternate.
10	x	x	TBT connect complete	Follow connect flow for thunderbolt.
00	0	1	Invalid	Follow disconnect flow for DP alternate.
01	0	0	Invalid	Do nothing right now
01	0	1	Invalid	Follow disconnect flow for DP alternate.
11	x	x	Invalid	Follow disconnect flow for DP alternate.

Refer to the TypeC Programming page for details on signaling between IOM and display driver.

BW_BUDDY1_PAGE_MASK

BW_BUDDY2_PAGE_MASK

Bandwidth Buddy Registers
These registers are used to improve bandwidth efficiency by pairing up memory requests with similar addresses. The mask register selects which address bits to compare when buddying up transactions. The mask must be programmed based on the memory type and memory controller attributes.
Abox1 and Abox2 are used for pixel data reads. Program the BW_BUDDY1 and BW_BUDDY2 registers.

Optimal programming of the BW_BUDDY_PAGE_MASK registers depends on the memory configuration used. Program the BW_BUDDY_PAGE_MASK according to the table below. For memory configurations not listed below, set the BW_BUDDY_CTL Disable bit.

MEMORY CHANNELS/Number of modules	MEMORY TYPE	BW_BUDDY_PAGE_MASK
1/1	DDR4	0x0000000F
1/1	DDR5	0x0000000F
2/1	LP4,LP5	0x0000001C
2/2	DDR4	0x0000001F
2/2	DDR5	0x0000001E
4/2	LP4,LP5	0x00000038

Data Buffer

DBUF_CTL

DBUF_STATUS

DBUF_ECC_STAT

DBUF_CTL2

See the Display Buffer Programming section for information on how to allocate the buffer to planes.

Backlight

This section refers to the CPU display backlight control over the utility pin. For PCH display backlight control, see South Display Engine Registers.

The backlight PWM output frequency is determined by the PWM clock frequency, increment, and frequency divider.

PWM output frequency = PWM clock frequency / PWM increment / PWM frequency divider

The frequency divider must be greater than or equal to the number of brightness levels required by software; typically 100 or 256.

Backlight Enabling Sequence

1. Enable utility pin, select PWM mode, and set polarity in UTIL_PIN_CTL Util Pin Enable, Util Pin Mode, and Util Pin Output Polarity.

2. Set frequency and duty cycle in BLC_PWM_DATA Backlight Frequency and Backlight Duty Cycle.

3. Enable PWM output and set granularity in BLC_PWM_CTL PWM Enable and PWM granularity.

...

4. Change duty cycle as needed in BLC_PWM_DATA Backlight Duty Cycle.

If needed, granularity and polarity can be programmed earlier in the enabling sequence.

Backlight Frequency Change Sequence

1. Disable PWM output in BLC_PWM_CTL PWM Enable.
2. Set new frequency and duty cycle in BLC_PWM_DATA Backlight Frequency and Backlight Duty Cycle.
3. Enable PWM output and set granularity in BLC_PWM_CTL PWM Enable and PWM granularity.

Backlight Registers

BLC_PWM_CTL

BLC_PWM_DATA

Miscellaneous Shared Functions

UTIL_PIN_CTL **UTIL_PIN_BUF_CTL**
UTIL2_PIN_CTL **UTIL2_PIN_BUF_CTL**
The utility pin(s) can be used for various functions, including MIPI DSI TE and genlock, on SoCs supporting those functions. The pins must be configured for those functions as part of the function enable and disable sequences.
AUDIO_PIN_BUF_CTL

Double Buffer Control

DOUBLE_BUFFER_CTL

Double Buffer Disabling/Stalling

Double buffer stalling (also called disabling) is used to synchronize register updates across multiple display resources for an atomic update. While stalled, double buffer registers can be written with new values, updating the 1st stage buffer, but the double buffering will not activate to transfer those values to the 2nd stage (live/working value) buffer to be used by the hardware resource. This allows for multiple register programming to cross the double buffer update point and keep the registers in sync.

Without double buffer stalling, updates to multiple registers can become un-synchronized if the double buffer update event (typically vblank rising edge) happens during the programming. Then some registers will have double buffer updates a frame before other registers and the screen contents will be incorrect.

The double buffer stalling is controlled by the global double buffer disable. Disabling double buffering means it is stalled.

- DOUBLE_BUFFER_CTL Global Double Buffer Disable register bit is used to stall double buffering in all pipes and transcoders.

Allow Double Buffer Stall

The double buffer stalling is also controlled by the Allow Double Buffer Update Disable register bit that each resource has in one of its control registers. The Allow Double Buffer Update Disable is useful if certain resources need to update freely and not be tied into the synchronizing of other resources, such as if cursor update needs to happen as soon as possible while some plane updates are being stalled to synchronize together.

The double buffering for a particular resource will only be stalled if that resource's Allow Double Buffer Update Disable is set and the global double buffer disable is set.

Details

This only stalls the double buffer update for periodic events, like the start of vertical blank. It does not change the behavior for constant events, like pipe not enabled.

Double buffer stalling does not stall asynchronous flips initiated by MMIO or command streamers.

Synchronous flips will not complete or give the flip done indication while double buffering is stalled for a plane. They will complete and give the flip done at the next double buffer update point after the double buffering is no longer stalled.

Sequence for synchronizing double buffer updates

1. If not already set, set the Allow Double Buffer Update Disable field for each resource to be synchronized together.
2. Set the Global Double Buffer Disable register bit. Double buffering is now stalled.
3. Program the registers that need to be synchronized together.
4. Clear the Global Double Buffer Disable register bit. Double buffering is now un-stalled. Any pending updates will take place at the next periodic update event.
5. Depending on configuration, variable refresh rate and PSR require extra programming to trigger a frame update after the registers have been updated. See the VRR and PSR programming pages.
6. If a resource no longer needs to be synchronized, clear the Allow Double Buffer Update Disable field for that resource. If the resource will continue to be synchronized, the field can remain set.

It is not necessary to set and clear the Allow Double Buffer Update Disable around every register update. Allow Double Buffer Update Disable only has to change if a resource's requirements for synchronization are changed.

Central Power

SAGV

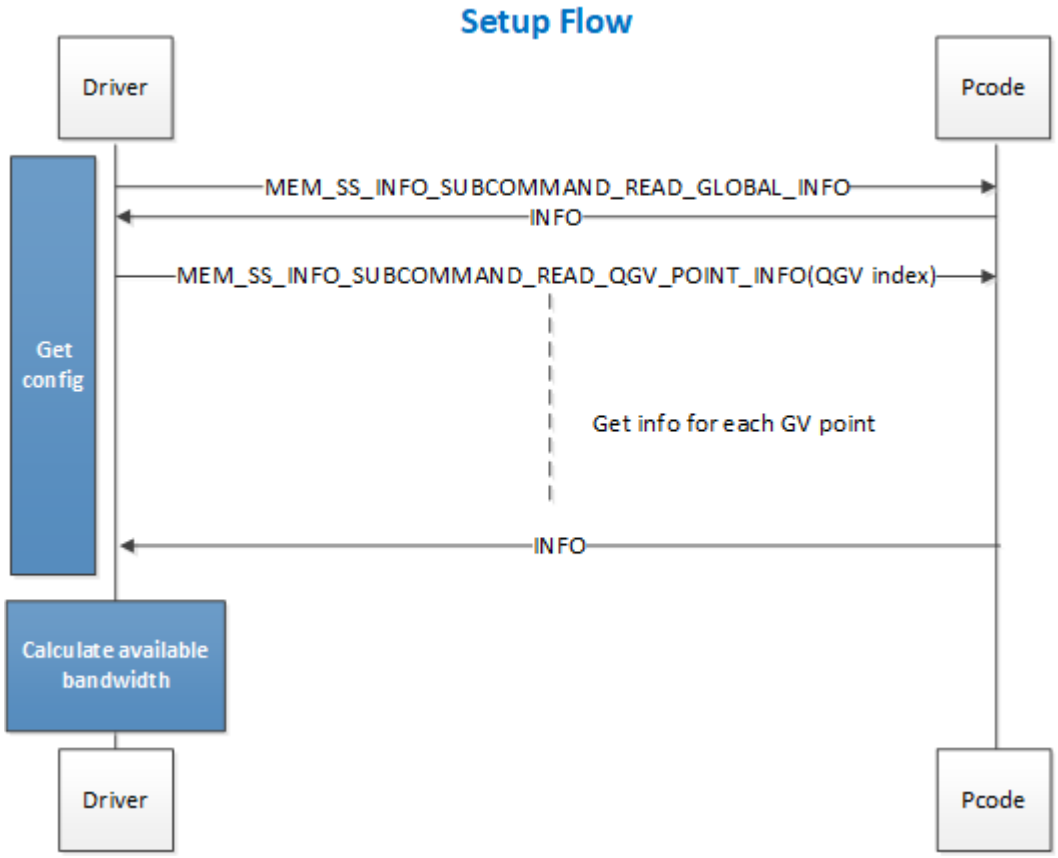
System Agent Geyserville (SAGV) dynamically adjusts the system agent voltage and clock frequencies depending on power and performance requirements. SAGV impacts display engine in two ways. SAGV point selections can limit the system memory bandwidth to display. SAGV transitions can temporarily block display engine access to system memory. Display software must restrict the SAGV point selection to control the bandwidth availability and setup watermarks to tolerate the temporary memory block.

SAGV Point Selection

Setup

Find the memory bandwidth availability for display. The results can be cached so that the flow does not have to be rerun.

The driver does not have to use the mailbox if it has other ways of finding the memory and GV point info.



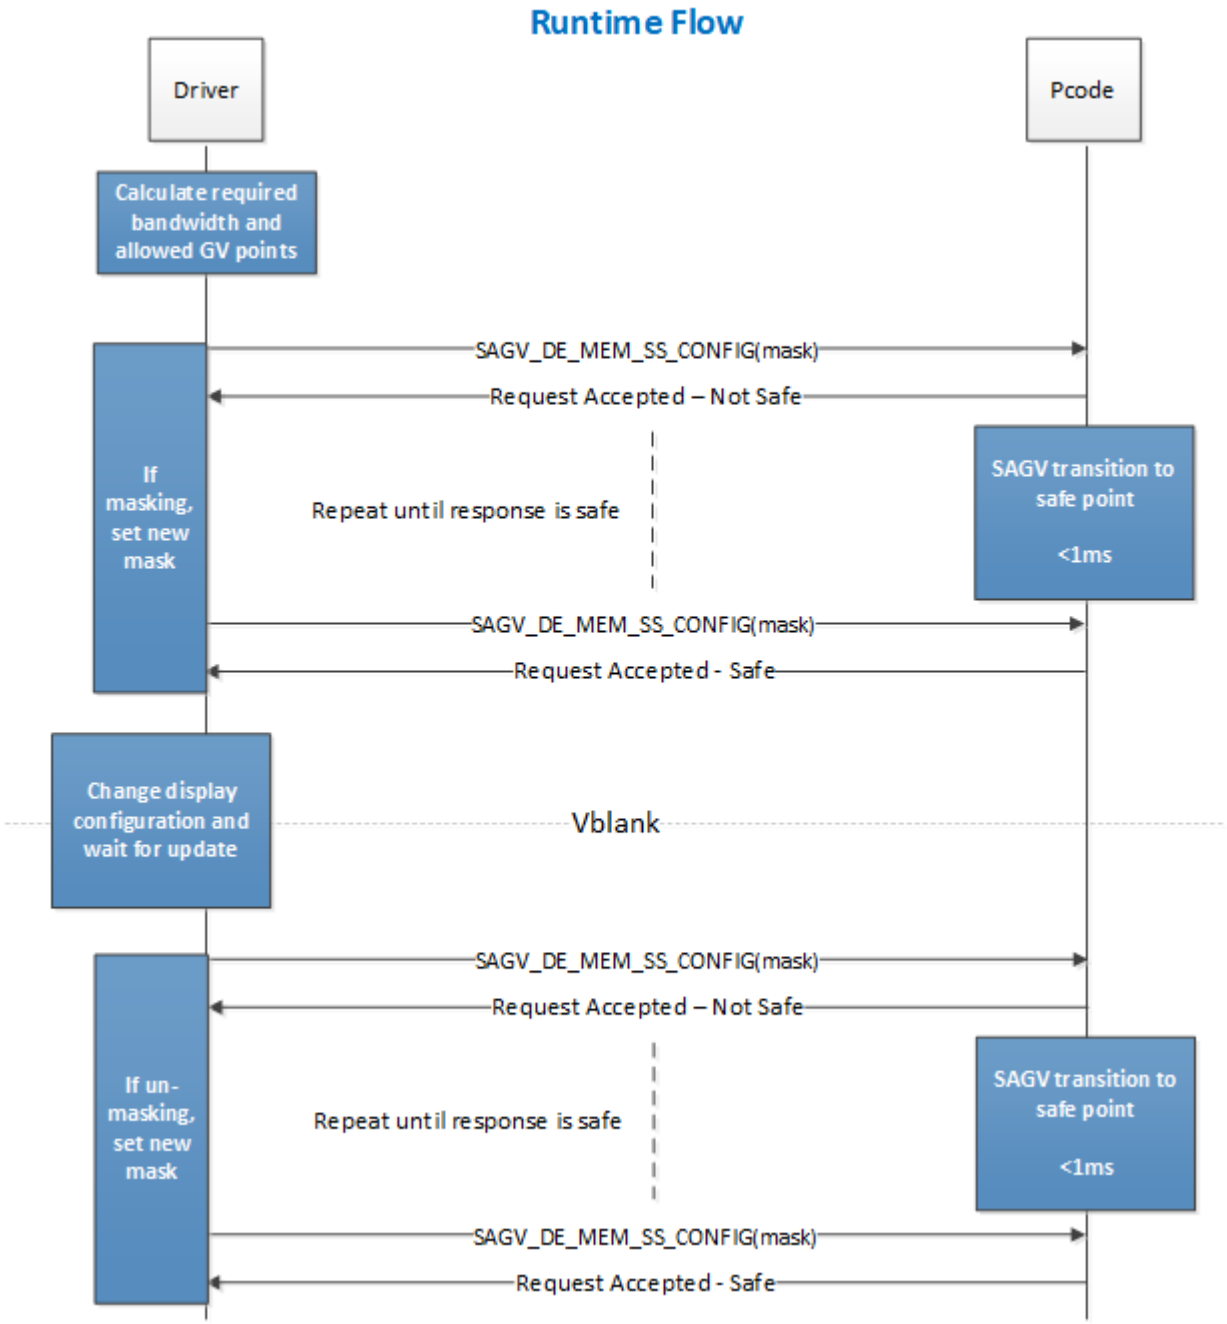
1. Driver reads memory subsystem (MEM SS, MemSS) configuration information from Pcode using the GT Pcode mailbox command MAILBOX_GTDRIVER_CMD_MEM_SS_INFO, first reading the global info and number of GV points, then reading GV info for each GV point.
    - Described in the Mailbox Commands section
2. Driver uses the mailbox info to calculate the available memory bandwidth for each GV point and number of enabled planes.
    - Described in the Bandwidth Restrictions chapter, Available Memory Bandwidth Calculation section.

There are cases where the highest numbered GV point allows less bandwidth for display than a lower point.

Overclocking reprogramming of memory parameters dynamically (system running without a reboot when changes are applied) can result in a display underrun since the display driver will not know that the configuration has changed.

Runtime

Adjust the allowed GV points to match display configuration changes.



1. Before changing display configuration in a way that impacts required bandwidth or number of planes, driver calculates the new bandwidth requirement.
    - Described in the Bandwidth Restrictions chapter, Required Memory Bandwidth Calculation section.
2. Driver finds which GV points supply enough available bandwidth to meet the required bandwidth and which GV points do not supply enough and must be restricted (masked off).
    - At least one GV point of each type must always remain unmasked. The GV point of each type providing the highest bandwidth for display must always remain unmasked.

- Each cycle through this sequence can only mask or unmask points of a GV type, not do both for a single GV type. It is allowed for one GV type to unmask while another masks, then one cycle through this sequence will mask one type of GV and the unmask another type of GV.
- If no GV point will provide enough bandwidth, then the display configuration must be constrained to fit within the available bandwidth.
- If driver has lost track of what was previously masked off, it can mask off all but the highest bandwidth point of each type to get to a known safe setting, then cycle through the full sequence again to set the correct mask.
- To disable SAGV when watermarks do not meet the SAGV block time requirement, mask off all the QGV points except for the point providing the highest bandwidth for display. To re-enable SAGV, unmask all of the QGV points that meet the bandwidth requirements for display. See the Watermark Calculations section for more info.

3. If masking GV points
    1. Driver uses GT Pcode mailbox command MAILBOX_GTDRIVER_CMD_SAGV_DE_MEM_SS_CONFIG to send Pcode the bitmask of restricted points and polls by repeatedly issuing the command with the same bitmask until receiving the acknowledge with point safe for each type, hitting a timeout after 1 millisecond, or receiving the error code.
        - Command described in the Mailbox Commands section
        - Pcode adjusts GV
            1. Pcode performs needed changes to ensure that all future transitions will be performed to the allowed states only.
            2. If pcode currently resides in a point which is restricted, it issues a GV transition to an allowed state.
            3. Pcode responds to the mailbox with point safe.
        - If only one type of GV is masking, keep the mask unchanged for other types.
4. Driver changes the display configuration
5. If unmasking GV points
    1. Driver waits for the configuration to be updated (typically at the next vertical blank). Driver can wait even longer, but should eventually complete unmasking in order to let GV move between points to give more optimal power and performance.
    2. Driver uses GT Pcode mailbox command MAILBOX_GTDRIVER_CMD_SAGV_DE_MEM_SS_CONFIG to send Pcode the bitmask of restricted points and polls by repeatedly issuing the command with the same bitmask until receiving the acknowledge with point safe for each type, hitting a timeout after 1 millisecond, or receiving the error code.
        - Command described in the Mailbox Commands section
        - Pcode adjusts GV
            1. Pcode performs needed changes to ensure that all future transitions will be performed to the allowed states only.

2. If pcode currently resides in a point which is restricted, it issues a GV transition to an allowed state.
3. Pcode responds to the mailbox with point safe.

- If only one type of GV is unmasking, keep the mask unchanged for other types.

All points are unrestricted by default until driver requests otherwise or BIOS disables SAGV.

Pcode will reset the bitmask from display on the graphics device function level reset (FLR).

The BIOS mailbox for SAGV gets precedence over Display Mailbox for GV request.

Display driver must allow at least one GV point of each type at all times. Driver must not mask off all the points of any type.

Display driver must wait for the previous GV point restriction to finish before starting a new restriction.

Legacy Behavior

The legacy command MAILBOX_GTDRIVER_CMD_DE_LTR_SETTING has the effect of masking off all but the highest numbered QGV point. the command continues to be supported and can be used as a limited alternative to MAILBOX_GTDRIVER_CMD_SAGV_DE_MEM_SS_CONFIG. The highest numbered QGV point is not always the highest bandwidth for display, and masking off more QGV points than necessary is not optimal for power and performance, so the legacy command is of limited use and should be phased out by newer software. Eventually a future project may de-feature the legacy command.

Mailbox Commands

Mailbox Access Routine

1. Ensure any previous GT Driver Mailbox transaction is complete
2. Write GT Driver Mailbox Data0=<request data 31:0> and GT Driver Mailbox Data1=<request data 63:32>
3. Write GT Driver Mailbox Interface RUN_BUSY=1, PARAM2=<parameter2>, PARAM1=<parameter1>, COMMAND=<command>
4. Poll GT Driver Mailbox Interface for RUN_BUSY==0
    - Timeout and fail after 150 us
    - Response COMMAND encoding listed below
5. Read GT Driver Mailbox Data0=<response data 31:0> and Data1=<response data 63:32>

MAILBOX_GTRDIVER_CMD_MEM_SS_INFO

This mailbox command provides the MemSS information requested by display. Pcode collates this information from MemSS registers, parses display relevant information and passes it to display on query. It contains subcommands selected through the field PARAM1[15:8] of the INTERFACE register.

MAILBOX_GTRDIVER_CMD_MEM_SS_INFO_SUBCOMMAND_READ_GLOBAL_INFO

Subcommand used to read MemSS global configuration.

Mailbox COMMAND=0xD and PARAM1=0x0

Response Data Bits	Description
3:0	DDR Type; 0:DDR4, 1:DDR5, 2:LPDDR5, 3:LPDDR4, 4:DDR3, 5:LPDDR3
7:4	Number of populated channels
11:8	Number of enabled QGV points

If GV is fused disabled, BIOS should configure GV such that only 1 point will be reported.

MAILBOX_GTRDIVER_CMD_MEM_SS_INFO_SUBCOMMAND_READ_QGV_POINT_INFO

Subcommand used to read QGV point related timing info. Input is the QGV index following the number of enabled QGV points from the global configuration. Out of bounds QGV index results in error code MAILBOX_GTDRIVER_CC_ILLEGAL_DATA error.

Mailbox COMMAND=0xD and PARAM1=0x1 and PARAM2=<QGV index, counting from 0>

Response Data Bits	Description
15:0	Dclk in multiples of 16.6666 MHz
23:16	TRP in DCLKs
31:24	tRCD in DCLKs
39:32	TRDPRE in DCLKs
48:40	TRAS in DCLKs

Pcode reports the maximums values from across multiple memory channels.

MAILBOX_GTDRIVER_CMD_SAGV_DE_MEM_SS_CONFIG

This mailbox command provides pcode with the bitmap containing the list of allowed GV operation points. Value of 1 in the mask is restricting the associated GV point.

Mailbox COMMAND=0xE

Request Data Bits	Description
0	Restricted QGV point 0
1	Restricted QGV point 1
2	Restricted QGV point 2
3	Restricted QGV point 3
4	Restricted QGV point 4
5	Restricted QGV point 5
6	Restricted QGV point 6
7	Restricted QGV point 7
Other bits	Reserved: Must program all 0s

The response data indicates when a safe GV point has been reached.

Response Data Encoding
Bit 1:0 0x0 = Request accepted. QGV point safe. 0x1 = Request accepted. QGV point not safe yet. Poll again. 0x2 = Request rejected error. QGV point cannot be be made safe. It may be blocked by a BIOS override or fuse. Retry with different points or fail.

The response command indicates if there were any errors.

Response COMMAND Encoding
00h = Success 03h = Illegal data or all GV points masked off 04h = Illegal subcommand 06h = Mailbox locked (BIOS loading not done or GV points not programmed or BIOS has only enabled a single GV point) 11h = Rejected (BIOS overriding the GV selection)

Pcode will quickly respond to accept the request, then take up to 1 millisecond (typically 100-200us) to move to a safe point. Driver has to poll Pcode with repeated MAILBOX_GTDRIVER_CMD_SAGV_DE_MEM_SS_CONFIG commands (with unchanged request data field) to find when the move to the safe point is complete.

MAILBOX_GTDRIVER_CMD_DE_LTR_SETTING (Legacy Command)

This mailbox command is the legacy method for disabling Qclk SAGV. It requests Pcode to move to the highest numbered enabled Qclk GV point and then hold there, equivalent to masking off all but one QGV point.

Mailbox COMMAND=0x21

Request Data Bits	Description
2:0	EL_THLD LTR Override: 0 = Disable Qclk GV 3 = Enable Qclk GV
3	Interlace Override: Unused must program with 0
4	VGA Override: Unused must program with 0
63:5	Reserved: Must program all 0s

The response data indicates when a safe Qclk point has been reached.

Response Data Encoding
0x0 = Request accepted. Qclk point not safe yet. Poll again.
0x1 = Request accepted. Qclk point safe.

Pcode will quickly respond to accept the request, then take up to 1 millisecond (typically 100-200us) to move to a safe point. Driver has to poll Pcode with repeated MAILBOX_GTDRIVER_CMD_DE_LTR_SETTING commands (with unchanged request data field) to find when the move to the safe point is complete.

Frame Buffer Compression

FBC Registers

FBC_CFB_BASE

FBC_CTL

DPFC_CONTROL_SA

DPFC_CPU_FENCE_OFFSET

FBC Overview

Frame Buffer Compression (FBC) gives a lossless compression of the display frame buffer to save power by reducing system memory read bandwidth and increasing the time between display engine reads to system memory.

FBC is only available on specific plane(s), depending on project. See FBC_CTL for details. FBC compresses pixels for the plane(s) it is attached to as they are displayed. The compressed data is written into the Compressed Frame Buffer (CFB) in graphics data stolen memory. The compressed data is then read the next time the same line needs to be displayed. Changes to the display front buffer (currently displayed memory surface) through host aperture (GMADR) tiling fences (on projects that support that), render (RCS), and blitter (BCS) are tracked and cause the compressed lines to be invalidated and recompressed. Flips or changes to plane size and panning cause the entire buffer to be recompressed (nuke).

FBC Compression Limit

The FBC compression limit reduces the size of the Compressed Frame Buffer (CFB) by limiting which lines will be compressed. This is used when the graphics stolen memory available for the FBC CFB is smaller than the size of the original uncompressed frame buffer. There is also a FBC compressed vertical limit, listed in FBC_CTL, which is the maximum number of lines FBC can compress. Lines beyond the vertical limit do not need to be accounted for in the CFB size.

When the compression limit is 1:1, every line is written to the CFB, so the CFB width is the same as the original uncompressed frame buffer.

When the compression limit is 2:1, only lines that compress to 1/2 their original size will be written to the CFB, so the CFB width can be 1/2 the original uncompressed frame buffer.

When the compression limit is 4:1, only lines that compress to 1/4 their original size will be written to the CFB, so the CFB width can be 1/4 the original uncompressed frame buffer.

DSM allocation in bytes = min (640, ceiling (plane height / 4))* Compressed buffer stride in cachelines * 64

The 16bpp plane pixel format requires compression limit to be 2:1 or 4:1.

Compressed buffer stride in cachelines = at_least (ceiling [plane_width_in_pixels / (32 * compression_limit_factor)] * 8 + 1)

FBC Programming Overview

1. Set up the compressed frame buffer.
    - The compressed buffer resides in graphics data stolen memory.
    - The stolen memory must be contiguous and un-cached.
    - The stolen memory needed for compressed frame buffer must be greater or equal to CFB size (calculation above).
    - Manage the compressed buffer size at run-time by balancing other graphics memory needs with the FBC allocation, and implement appropriate memory needs prioritization schemes.
2. Tracking for CPU host front buffer modifications
    - CPU Host Front Buffer Tracking sequence below
3. Tracking for display front buffer rendering
    - Render Tracking sequence below
4. Tracking from display front buffer BLTs
    - Blitter Tracking sequence below

LRI commands to MSG_FBC_REND_STATE are used as part of the render and blitter tracking. Those LRIs must be followed SRM commands to the same address.

LRI to MSG_FBC_REND_STATE with data 0x00000004 tells FBC to nuke and invalidate the entire compressed buffer.

Render Tracking With Nuke

- Software must send the nuke LRI after each render to the display front buffer

1. Render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL
    c. LRI to MSG_FBC_REND_STATE with data 0x00000004 (nuke)
    d. SRM to read MSG_FBC_REND_STATE and store to a scratch page
2. More render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL

c. LRI to MSG_FBC_REND_STATE with data 0x00000004 (nuke)
d. SRM to read MSG_FBC_REND_STATE and store to a scratch page

3. Render commands that do not touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL

Blitter Tracking With Nuke

- Software must send the nuke LRI after each BLT to the display front buffer. Never set 221d0h bit 3 (Address Valid for FBC).

1. BLT commands that touch the display front buffer
    a. BLT submission
    b. MI_FLUSH_DW
    c. LRI to MSG_FBC_REND_STATE with data 0x00000004 (nuke)
    d. SRM to read MSG_FBC_REND_STATE and store to a scratch page
2. More BLT commands that touch the display front buffer
    a. BLT submission
    b. MI_FLUSH_DW
    c. LRI to MSG_FBC_REND_STATE with data 0x00000004 (nuke)
    d. SRM to read MSG_FBC_REND_STATE and store to a scratch page
3. BLT commands that do not touch the display front buffer
    a. BLT submission
    b. MI_FLUSH_DW

MSG_FBC_REND_STATE address for pipe A FBC is 0x50380

CPU Host Front Buffer Tracking

- Host tracking must be setup by software, then hardware will track FBC line invalidations to the specified fence in the graphics aperture.
    1. Program Y offset from the CPU fence to the Display Buffer base in DPFC_CPU_FENCE_OFFSET.
    2. Program CPU fence ID and enable CPU fence tracking in DPFC_CONTROL_SA.
    3. Disable CPU Fence tracking in DPFC_CONTROL_SA if no tiling fence is mapped to display buffer.

Display Plane Enabling with FBC

- FBC has to be enabled after the attached display plane is enabled.
- This is the general sequence. See FBC_CTL for any workarounds.
  1. Enable display plane
  2. Enable FBC as described in FBC_CTL register

Display Plane Disabling with FBC

- FBC has to be disabled at least one frame before FBC attached display plane disabling.
- This is the general sequence. See FBC_CTL for any workarounds.
  1. Disable FBC as described in FBC_CTL register.
  2. Wait for at least one start of vblank for the disable double-buffering.
  3. Disable display plane.

Watermarks

The watermark registers are used to control the display to memory request timing. The watermarks must be programmed according to the Display Watermark Programming section.

Plane and cursor watermark registers are in the planes section.

FUSE_STATUS

Functions Within Each Well

Except where noted, the registers for a function reside within the same power well as that function.

Note: Some views of the PRM will show a power domain within each register definition. Those domains may be incorrect.

- PG0 contains the functions for the graphics PCI device and bringing up the display
  - PCI
  - Clocks
    - The port PLLs are in the PLL and IO/PHY/AFE power domains and require power enabling which is explained in the mode set sequences
  - Shared Functions
    - Interrupts are in PG0, except for pipe interrupts which reside in the power wells associated with the pipes.
    - MBus, except for PIPE_MBUS_DBOX_CTL which reside in the power wells associated with the pipes.
    - Data Buffer (DBUF) registers are in PG0, but the function is in PG1.
  - Central Power, except for FBC which resides in PG1.
  - Top Level GTC. DDI Level GTC is in the power well associated with each DDI.
- PG1 contains the functions for pipe A display on eDP or MIPI DSI, without VDSC.
  - Data Buffer (DBUF) function is in PG1, but the registers are in PG0.
  - Pipe A and associated Planes, except for VGA.
  - Transcoder A, including PSR
  - Transcoder DSI
  - DDI A-C, including Aux. See note below about IOs.
  - FBC
  - DSS
- PG2 contains the functions for VDSC on pipe A
  - VDSC/joining for pipe A.
- PG3 the functions for pipe B, external displays, and VGA.
  - Pipe B and associated Planes and VDSC/joining
  - Audio
  - Transcoder WD
  - VGA. The VGA_CONTROL register is in PG0, but requires PG3 to be enabled before VGA is enabled.
  - Transcoder B
  - DDI USBC1-6, including Aux. See note below about IOs.
  - KVMR. Hardware will automatically enable PG2 and PG3 for KVMR.

- PG4 contains pipe C.
    - Pipe C and associated Planes and VDSC/joining
    - Transcoder C (registers reside in PG3, but access path goes through associated pipe)
- PG5 contains pipe D.
    - Pipe D and associated Planes and VDSC/joining
    - Transcoder D (registers reside in PG3, but access path goes through associated pipe)
- The port PLLs and IOs and Aux IOs are in the IO/PHY/AFE power domains and require power enabling which is explained in the mode set sequences.
    - For typeC ports, there are separate Aux channel IO power domains for thunderbolt (TBT fields) and for non-thunderbolt (USBC fields).

Enable Sequence

PG0 -> PG1 -> PG2 -> PG3 -> PG4 -> PG5

Power wells must be enabled sequentially and no intermediate power well can be skipped.

1. **PG0 is controlled by the CPU power controller and will be automatically enabled any time software accesses display**
2. **PG1 is enabled using** Sequences to Initialize Display
3. **To turn on VDSC with pipeA**
    a. PG1 must be turned on first (display initialization sequence will turn PG1 on)
    b. Enable PWR_WELL_CTL Power Well 2 Request
    c. Wait for PWR_WELL_CTL Power Well 2 State == Enabled, timeout after 20 us
    d. Wait for FUSE_STATUS FUSE PG2 Distribution Status == Done, timeout after 20 us
4. **To turn on PipeB, PG1 and PG2 must be turned on and then do the following to turn on PG3**
    a. Enable PWR_WELL_CTL Power Well 3 Request
    b. Wait for PWR_WELL_CTL Power Well 3 State == Enabled, timeout after 20 us
    c. Wait for FUSE_STATUS FUSE PG3 Distribution Status == Done, timeout after 20 us
5. **To turn on PipeC, PG1, PG2, and PG3 must be turned on and then do the following to turn on PG4**
    a. Enable PWR_WELL_CTL Power Well 4 Request
    b. Wait for PWR_WELL_CTL Power Well 4 State == Enabled, timeout after 20 us
    c. Wait for FUSE_STATUS FUSE PG4 Distribution Status == Done, timeout after 20 us
6. **To turn on PipeD, PG1, PG2, PG3 and PG4 must be turned on and then do the following to turn on PG5**
    a. Enable PWR_WELL_CTL Power Well 5 Request
    b. Wait for PWR_WELL_CTL Power Well 5 State == Enabled, timeout after 20 us
    c. Wait for FUSE_STATUS FUSE PG5 Distribution Status == Done, timeout after 20 us

Disable Sequence

Power wells have to be turned off in the reverse order of the enabling. The following sequence should be followed to disable each power well

1. Disable PWR_WELL_CTL Power Well # Request
2. Wait for PWR_WELL_CTL Power Well # State == disabled, timeout after 20 us

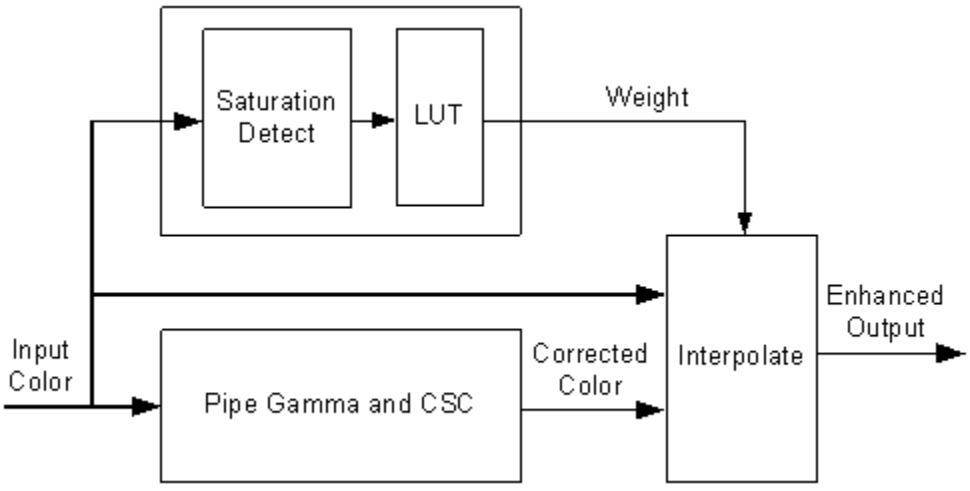
Pipe

Pipe Color Gamut Enhancement

Pipe color gamut enhancement is used to enhance display of standard gamut content on wide gamut displays. It processes the color value from before and after the pipe gamma and color space correction blocks to create the color gamut enhanced output. The typical usage is to output the pipe gamma and CSC corrected color for areas of low saturated content and the input (not gamma or CSC corrected) color for areas of high saturated content. It is not recommended to use color gamut enhancement with wide gamut inputs.

CGE_CTRL
CGE_WEIGHT

The pipe Gamma and CSC must be programmed to either the split gamma mode or gamma after CSC mode when using pipe color gamut enhancement.



The saturation level of the pipe gamma and CSC input color is detected and used to index into a look up table (LUT) containing programmable weights. The saturation values are linearly distributed across the LUT indexes from the lowest index for lowest saturation to the highest index for highest saturation.

The enhanced output color is created by using the weight value to interpolate between the input color and corrected color. See the following table of weights to amount of input or corrected color used to create the enhanced output color.

Weighting of input and corrected colors

Weight from LUT	Amount of Input Color in Enhanced Output	Amount of Corrected Color in Enhanced Output
00 0000b (minimum)	0%	100%
...	...	...
00 1000b	25%	75%
...	...	...
01 0000b	50%	50%
...	...	...
01 1000b	75%	25%
...	...	...
10 0000b (maximum)	100%	0%

Example weight programming

CGE LUT Index	CGE Weight Value Decimal	CGE Weight Value Binary	CGE Weight Percent Input Color	CGE Weight Percent Corrected Color
0 (lowest saturation)	0	00 0000b	0%	100%
1	0	00 0000b	0%	100%
2	0	00 0000b	0%	100%
3	0	00 0000b	0%	100%
4	0	00 0000b	0%	100%
5	0	00 0000b	0%	100%
6	1.6	00 0010b	5%	95%
7	3.2	00 0011b	10%	90%
8	4.8	00 0101b	15%	85%
9	6.4	00 0110b	20%	80%
10	8.64	00 1001b	27%	73%
11	12.8	00 1101b	40%	60%
12	19.2	01 0011b	60%	40%
13	25.6	01 1010b	80%	20%
14	28.8	01 1101b	90%	10%
15	32	10 0000b	100%	0%
16 (highest saturation)	32	10 0000b	100%	0%

HDR

High Dynamic Range (HDR)

Key HDR features

- HDR mode supports up to 3 planes in each pipe.
- Tone mapping support in planes.
- Linear blending of HDR planes.
- Linear scaling support in planes and pipes.
- Dedicated chroma upsampler to handle YUV420.
- Programmable color space convertors in planes/cursor.
- Enhanced gamma mode for PQ encoding.

Hardware Capabilities

FP16 Normalizer:

FP16 Normalizer normalize the pixels to -1.0 to 1.0 range. FP16 Normalizer is programed in the PLANE_PIXEL_NORMALIZE register. The programmed FP16 value gets multiplied with the pixel value for normalizing them. Out of band values get clamped to -1.0 to 1.0 value. The output of this block directly feeds into plane CSC block bypassing Chroma up-sampler, input CSC and de-gamma. The FP16 source content must be linear with no gamma encoding.

Chroma up-sampler:

HDR planes have a dedicated bi-linear Chroma up-sampler for converting P0xx/NV12 source pixel formats to YUV444. Supports up to 4k resolution. Chroma up-sampler is programmed in the PLANE_CUS_CTL register.

CUS supports 4 different chroma siting positions that can be programmed through the initial phase. For initial phase programming, refer PLANE_CUS_CTL.

Input CSC:

A programmable 3x3 color space converter generally used for converting YUV content to RGB. This operates in non-linear space. Plane input CSC is programmed in the PLANE_INPUT_CSC_* registers along with the enable bit in the PLANE_COLOR_CTL register.

Plane pre-CSC Gamma:

Plane de-gamma LUT is used for linearizing HDR or SDR source content with gamma. The 128 entries LUT is uniformly spaced with additional 3 entries for 1.0,3.0 and 7.0. Plane input CSC is programmed in the PLANE_PRE_CSC_GAMC_INDEX_ENH and PLANE_PRE_CSC_GAMC_DATA_ENH registers along with the enable bit in the PLANE_COLOR_CTL register.

Plane CSC:

The programmable plane CSC can be used for color space conversion of source content to BT.2020 or panel color gamut. Plane CSC is programmed in the PLANE_CSC_* registers along with the register bit in the PLANE_COLOR_CTL register.

Plane post-CSC Gamma:

In HDR mode, this block can be used for tone mapping/dynamic range adjustment of each source content to a common reference luminance range before blending. The LUT must be programmed to use "Multiply mode" in the PLANE_POST_CSC_GAMC_INDEX_ENH, PLANE_POST_CSC_GAMC_DATA_ENH and PLANE_COLOR_CTL registers.

Hardware computes the pseudo luminance of the incoming pixel using the following equation, uses it index the LUT and compute an adjustment factor 'F'. Toned mapped output R, G and B values are computed by scaling the input R, G and B channel by 'F'.

Lin = 0.25*Red input + 0.625*Green input + 0.125*Blue input.

Plane scaling:

Plane scaling is supports both linear and non-linear scaling modes. The scaling mode is programmed in the PS_CTRL. In HDR mode, scaling and blending operations are generally performed in linear mode.

Linear Blending:

With precision improvements, hardware supports blending in linear mode. Linear blending is enabled by programming the HDR mode bit in the PIPE_MISC register.

Cursor:

For HDR usages, the cursor plane supports a programmable De-gamma LUT, Color Space Convertor and a Luminance scaler. Luminance scaler scales each color component by a programmed 10 bit value fractional value.

Cursor de-gamma LUT is programmed in in CUR_PRE_CSC_GAMMA_INDEX and CUR_PRE_CSC_GAMMA_DATA registers along with the enable bit in CUR_CTL. Cursor CSC is programmed in the CUR_CSC_COEFF register along with the enable bit in CUR_CTL. Luminance scaling is enabled and programmed in CUR_COLOR_CTL.

Pipe Scaler:

Pipe scaler supports linear scaling.

Pipe Gamma:

Supports a 12 bit multi-segmented gamma mode that provides high quality HDR PQ encoding. Refer to the "Pipe Palette and Gamma" page for details

Pipe LDPST

DPLC_CTL

DPLC_HIST_INDEX

DPLC_HIST_DATA

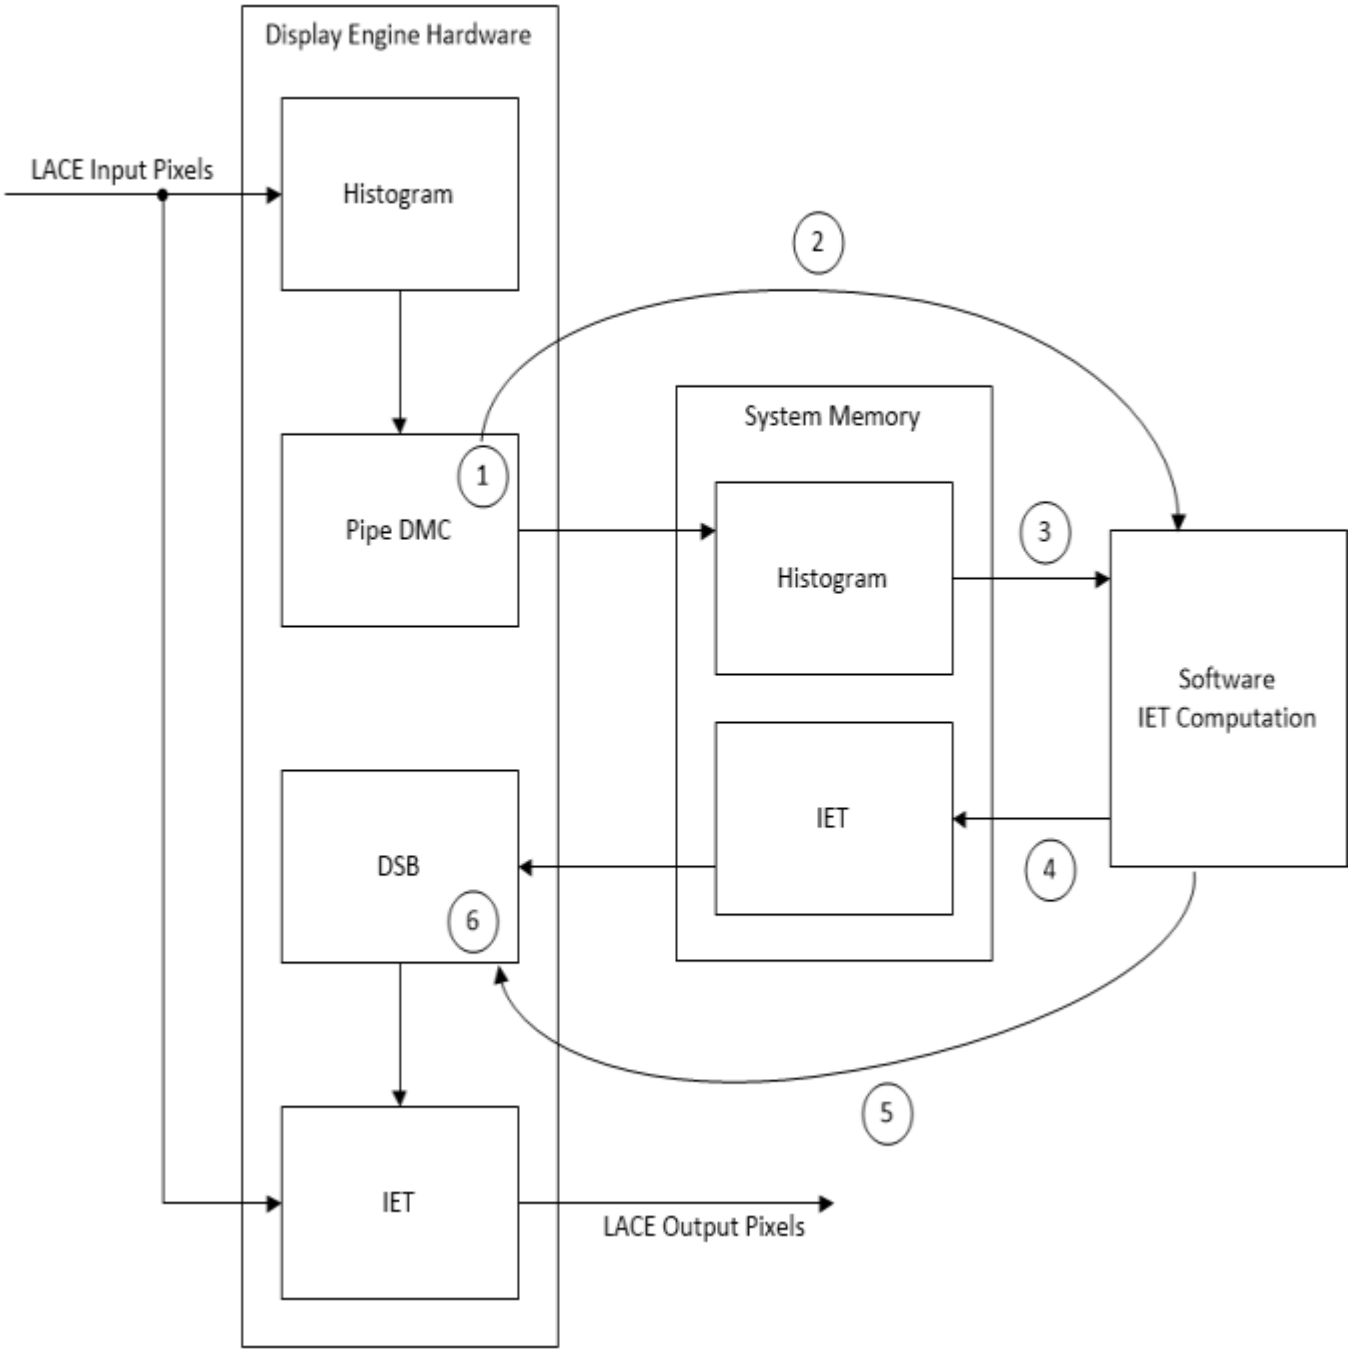
DPLC_IE_INDEX

DPLC_IE_DATA

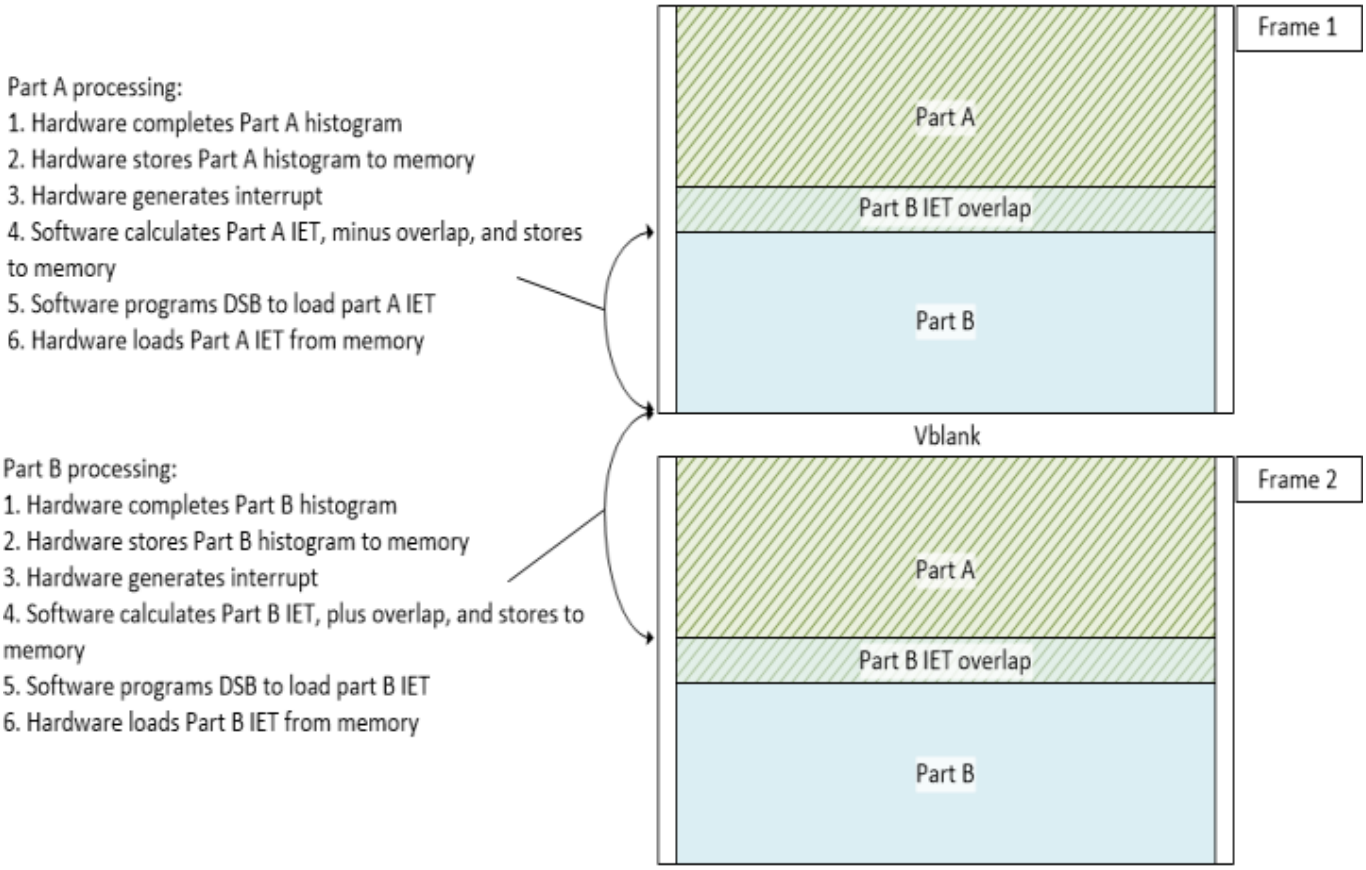
Fast LACE Access

The fast LACE access improves the latency for programming LACE by moving histogram and image enhancement table (IET) programming to system memory instead of display engine MMIO. This also allows software to write updates only to IET tiles that have changes, instead of writing them to all IET tiles when there is any change.

1. DMC reads LACE histogram data and writes it into a system memory location indicated by display driver.
2. DMC triggers interrupt to driver.
3. Display driver reads histogram data and computes IET.
4. Display driver writes IET into system memory in DSB data format. If the same memory surface is used for multiple frames, driver can skip writing any tiles that do not need update since memory will hold the old values of those tiles.
5. Driver programs DSB to start loading IET.
6. DSB reads the IET data from system memory and writes into LACE IET.



To reduce the latency between histogram computation and IET application to 1 frame, each active frame is broken roughly in half, into part A and part B. While hardware computes the histogram of one part, software works on computing IET for the other part. The size of part A and B is programmable in number of LACE tile rows. The part B IET overlaps part A by one tile row in order to provide a smooth transition across parts.



Registers

DPLC_PART_CTL

DPLC_PTRCFG

DPLC_PTRCFG_LIVE

DPLC_RDLENGTH

DPLC_RDLENGTH_LIVE

DPLC_FA_STATUS

DPLC_FA_IMR

DPLC_FA_IIR

DPLC_FA_SURF

DPLC_FA_SURF_LIVE

Part Start and End Programming

Tile Size = 256

Tile Columns = CEILING(Pipe Horizontal Source Size / Tile Size)

Part A Start Tile Row = 1

Part A End Tile Row = FLOOR(Pipe Vertical Source Size / 2 / Tile Size) + 1

Part A Tile Rows = Part A End Tile Row

Part B Start Tile Row = Part A End Tile Row + 1

Part B End Tile Row = CEILING(Pipe Vertical Source Size / Tile Size)

Part B Tile Rows = 1 + Part B Start Tile Row - Part B End Tile Row

The row number programming is zero based, so subtract 1 from these values when programming PART CTL.

Resolutions with less then 3 tile rows in part A or part B are not supported.

Example

5120x3200 pipe source size

Tile Size = 256

Tile Columns = 20

Part A Start Tile Row = 1 (program 0)

Part A End Tile Row = 7 (program 6)

Part A Tile Rows = 7

Part B Start Tile Row = 8 (program 7)

Part B End Tile Row = 13 (program 12)

Part B Tile Rows = 6

Pointer Config Programming

The pointer config and read length are used by hardware to read out the histogram at the end of each part.

Part A X, Y, and DW Indexes = 0.

Part B X and DW Indexes = 0. Part B Y Index = Part B Start Tile Row.

Part A read length = Part A Tile Rows * Tile Columns * DWords per tile

Part B read length = Part B Tile Rows * Tile Columns * DWords per tile

The index values are programmed in the pointer config register, using the same format as DPLC_HIST_INDEX.

DSB Programming

DPLC_IE_INDEX

Part A X, Y, and DW Indexes = 0.

Part B X and DW Indexes = 0. Part B Y Index = Part B Start Tile Row - 1.

DPLC_IE_DATA

Part A number of IE data DWords written by DSB = (Part A Tile Rows - 1) * Tile Columns * DWords per tile

Part B number of IE data DWords written by DSB = (Part B Tile Rows + 1) * Tile Columns * DWords per tile

Overall Sequence

1. Driver setup LACE with fast access
    a. Load DMC Fast LACE access program.
    b. Program DPLC_FA_SURF_PARTA with the memory base address for part A histogram.
    c. Program DPLC_FA_SURF_PARTB with the memory base address for part B histogram.
    d. Write DPLC_CTL to enable LACE function, Fast Access Enable, select enhancement mode. IE Enable is OFF.
    e. Write DPLC_PART_CTL, DPLC_RDLENGTH_LIVE, and DPLC_PTRCFG with partA/PartB programming.
    f. Write DPLC_FA_IMR to unmask histogram copy done interrupts. Other interrupts are optional for error handling.
    g. Configure pipe interrupts to unmask and enable LACE interrupt.
    h. Write DPLC_CTL to enable correction - IE Enable.
2. DMC execution triggered at the end of part A
    a. Read DPLC_RDLENGTH_LIVE_PARTA to obtain number of reads to issue.
    b. Move DPLC_PTRCFG_LIVE_PARTA to DPLC_HIST_INDEX to start histogram reads for part A.
    c. Read DPLC_HIST_DATA as many times as programmed in DPLC_RDLENGTH_LIVE_PARTA.
    d. Write as many cachelines to system memory for part A to the base address specified in DPLC_FA_SURF_PARTA.
    e. Flush writes with a read to the last write location, ignoring the read return value.
    f. Write DPLC_FA_STATUS to clear Part A Histogram Ready and set Part A Histogram Copy Done.
3. Driver
    a. Receive Part A Histogram Copy Done interrupt.
    b. Read histogram part A from system memory at the base address specified in DPLC_FA_SURF_PARTA.
    c. Calculate PART A IET.
    d. Configure DSB with IET part A programming.
    e. Poll for DSB Idle.
    f. Load DSB HTP.
4. DSB
    a. Write DPLC_IE_INDEX to start IET data load.
    b. Write DPLC_IE_DATA entries.
    c. Write DPLC_FA_STATUS to set Part A Load IE.
5. DMC execution triggered at the end of part B
    a. Read DPLC_RDLENGTH_LIVE_PARTB to obtain number of reads to issue.
    b. Move DPLC_PTRCFG_LIVE_PARTB to DPLC_HIST_INDEX to start histogram reads for part B.
    c. Read DPLC_HIST_DATA as many times as programmed in DPLC_RDLENGTH_LIVE_PARTB.
    d. Write as many cachelines to system memory for part B to the base address specified in DPLC_FA_SURF_PARTB.
    e. Flush writes with a read to the last write location, ignoring the read return value.
    f. Write DPLC_FA_STATUS to clear Part B Histogram Ready and set Part B Histogram Copy Done.

6. Driver

a. Receive Part B Histogram Copy Done interrupt.
b. Read histogram part B from system memory at the base address specified in DPLC_FA_SURF_PARTB.
c. Calculate PART B IET.
d. Configure DSB with IET part B programming.
e. Poll for DSB Idle.
f. Load DSB HTP.

7. DSB

a. Write DPLC_IE_INDEX to start IET data load.
b. Write DPLC_IE_DATA entries.
c. Write DPLC_FA_STATUS to set Part B Load IE.

8. Go to 2

Fast Access Status and Interrupts

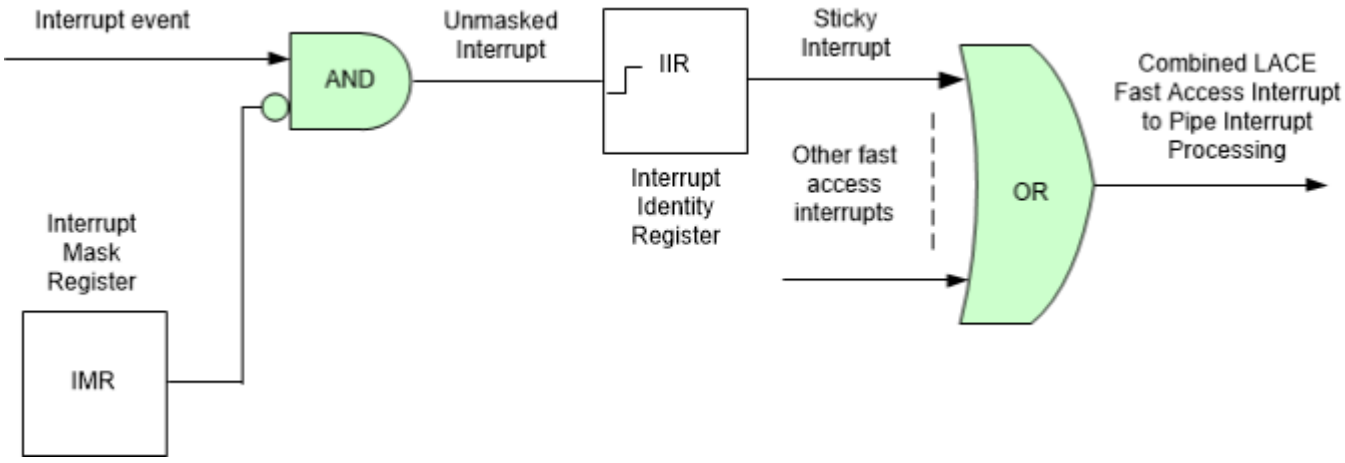
Interrupt Structure



DSB Engine Programming

Display State Buffer Programming

A DSB (Display State Buffer) is a queue of MMIO instructions in the memory which can be offloaded to DSB HW in Display Controller. DSB HW is a DMA engine that can be programmed to download the DSB from memory. It allows driver to batch submit display HW programming. This helps to reduce loading time and CPU activity, thereby making the context switch faster.

It can be chiefly used as an extension of the current flip programming

There are three DSB DMA engines per pipe.

Different DSB's are required if different tasks need to be accomplished simultaneously

DSB's can access only the pipe, plane, and transcoder Data Island Packet registers.

DSB cannot access any registers outside pipe registers, including, but not limited to FBC, clocks, audio, Aux channel, Power Wells, HPD.

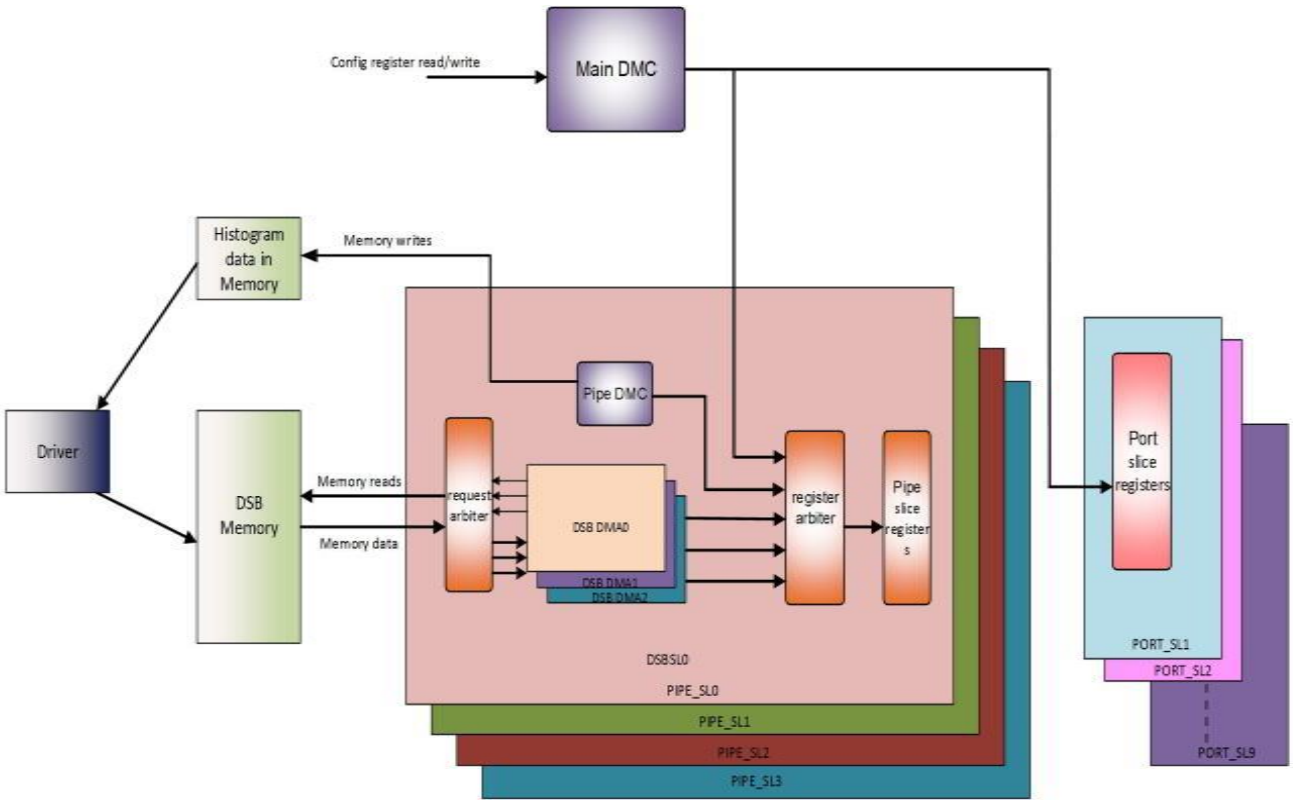
DSB HW can support only register writes (both indexed and direct MMIO writes). There are no registers reads possible with DSB HW engine.

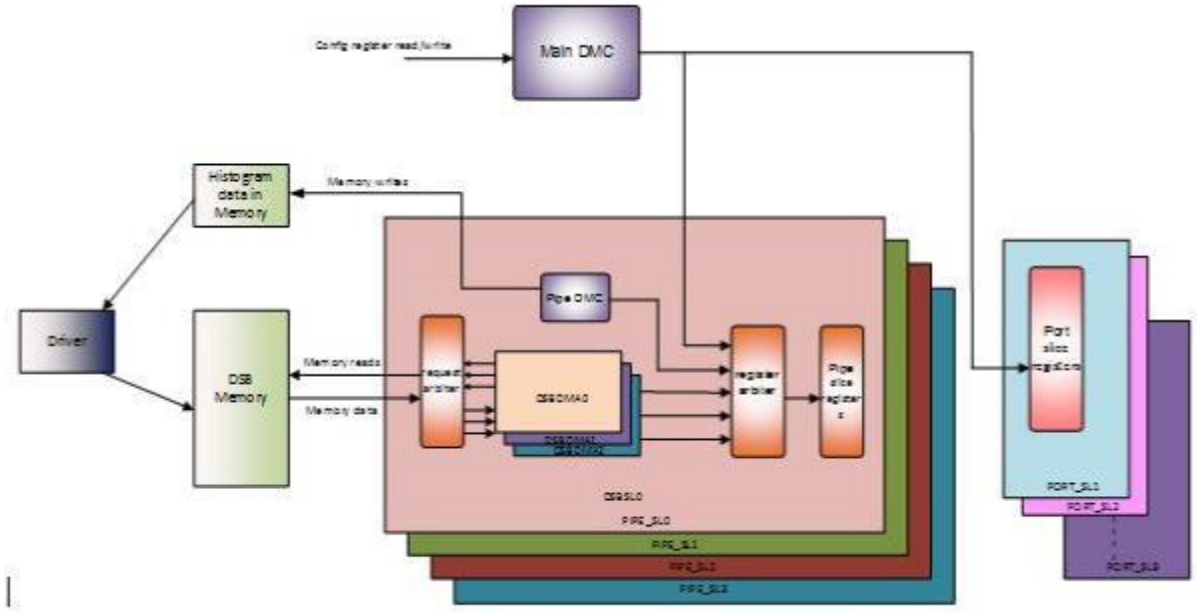
DSB HW has poll function capability.

DSB HW can be used in FAST LACE programming.

DSB HW can be used in HDR Meta data programming.

Below is the block diagram of the DSB HW and shows the general flow of the HW and SW flow. Driver will upload the Display State Buffer with instructions to program the Pipe registers.





Following registers will be used in the DSB HW. Software must ensure correct programming of these registers for the proper function of the HW. Illegal/incorrect programming of these register may result in unexpected behavior of hardware.

DSB HW Registers

DSB_CTRL

DSB_BUFRPT_CNT

DSB_HEAD_PTR

DSB_TAIL_PTR

DSB_MMIOCTRL

DSB_POLLMASK

DSB_POLLFUNC

DSB_INTERRUPT

DSB_PF_LN_LOWER

DSB_PF_LN_UPPER

DSB_PMCTRL

DSB_PMCTRL_2

DSB_CURRENT_HEAD_PTR

DSB_RM_TIMEOUT

DSB_RMTIMEOUTREG_CAPTURE

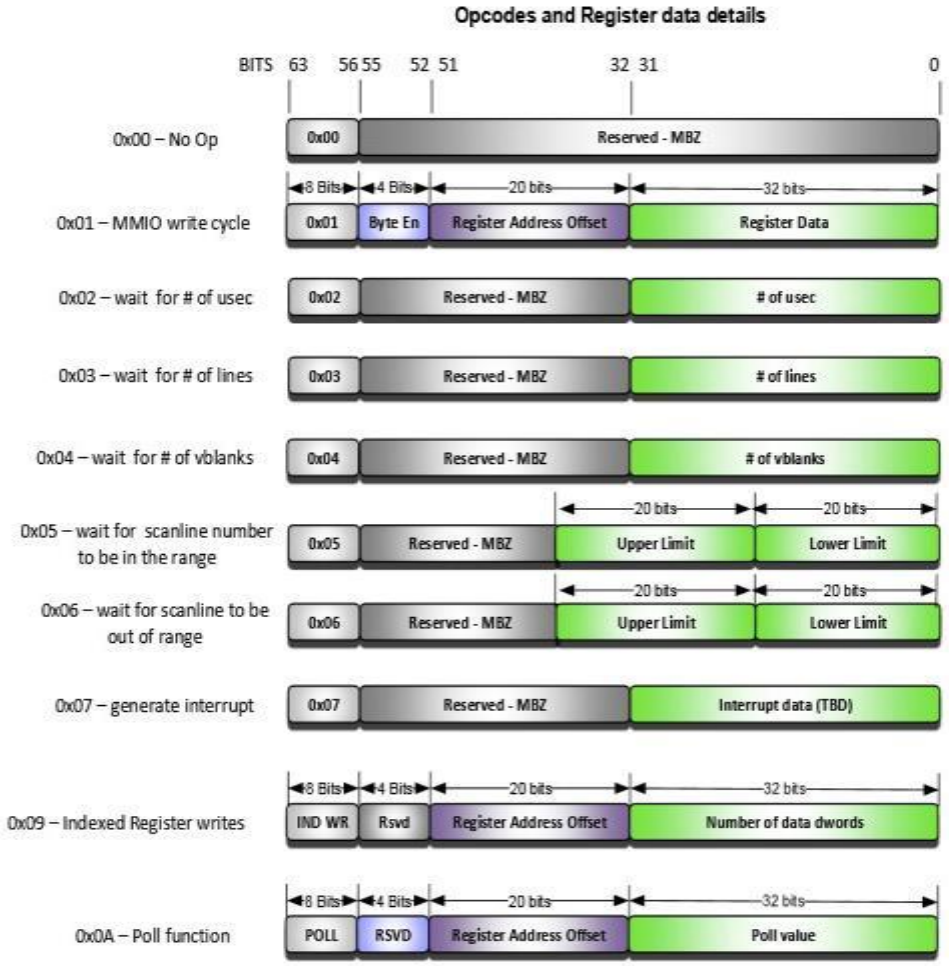
DSB_INTERRUPT

DSB_STATUS

PIPEDMC_CONTROL

DSB Instructions

The following DSB instructions are supported by the DSB HW. Software must upload the instructions in the defined format shown below.



Below are some examples of the DSB instructions format in the memory.

63	31	0	
20000000 10000000	09F7227c 00000003	00000008 00000007 00000006 00000005 00000004 00000003 00000002 00000001	09F7227c 00000008	0xh03000000

General Programming Sequence of the DSB HW

1. Driver will form a display state buffer using the supported DSB instructions to program the display registers and upload it in the memory.

2. Driver must program the **DSB_CTRL** register to enable the DSB engine. SW may choose to start the DSB DMA engine to start the memory requests right away or wait for a vblank to trigger the DSB DMA engine. SW may also chose to repeat to play the the same buffer again on every vblank by setting re-iterate bit of the **DSB_CTRL** register. SW must follow the programming rules defined in the **DSB_CTRL** register bits.

3. Driver cannot update or modify the DSB registers within the DSB program.

4. Driver must program the **DSB_HEAD_PTR** with the first cacheline address of the program and **DSB_TAIL_PTR** with the last cacheline address of the DSB program plus one. DSB HW DMA engine will be triggered on the tail pointer update.

- Head and Tail Pointers (32 bits each).
- SW must make sure that there must atleast one cacheline in the DSB program when updating Head and Tail pointer. i.e. head and tail pointer cannot be equal.
- Cacheline aligned graphics address.
- TP points to last location+1 cacheline address.
- SW should not modify these DSB registers when DSB is busy.
- Each cacheline can have 8 instructions.
- 64 bits per instruction.
- Fill incomplete cachelines with NoOps
- Cacheline data is in little Endian.
- One DSB can write to the registers of the another DSB engine within the pipe.

5. Driver can poll on the DSB Status bit in the **DSB_CTRL** register to check if the DSB engine has completed. If DSB program has an interrupt instruction as the last instruction then an interrupt will generated to SW which can be used to check the status the DSB DMA engine.

- SW can enable the interrupts by programming the appropriate enabled in **DSB_INTERRUPT** register.
- A pipe interrupt at **DE_PIPE_INTERRUPT** will be generated when interrupts are correctly enabled in the IMR and IER registers. Bits 13,14,15 shows the status of interrupts from each DSB engine.
- SW must clear the sticky bits in the **DSB_INTERRUPT** first and then clear the ISR bits in the **DE_PIPE_INTERRUPT**

6. Each of the instructions are described below in detail. Each of the supported functions/capabilities are also described that SW can use to program DSB HW. Every instruction must start at a 64 bit boundary.

NOOPs

The opcode of this instruction is 0x00. All the instructions must start and end on the cacheline boundaries. NoOPs can be used to complete the cachelines. All the 64 bits of this instruction are 0's.

MMIO Writes

The opcode of this instruction is 0x01. Lower 32 bits of the instruction is the MMIO write data. Bits 51:32 is the offset address of the MMIO write. Bits 55:52 are the byte enables of the mmio write instruction.

Wait for number of Microseconds

The opcode of this instruction is 0x02. The lower 32 bits of the instructions will have the number of microseconds to wait. DSB HW will wait for the programmed number of micro seconds before processing the next instruction.

Wait for number of lines

The opcode for this instruction is 0x03. The lower 32 bits of the instruction has the number of lines to wait. DSB HW will wait for the programed number of lines before processing the next instruction.

Wait for number of vblanks

The opcode for this instruction is 0x04. The lower 32 bits of the instruction has the number of vblanks to wait. DSB HW will wait for the programed number of vblanks (pipe undelayed vblank) before processing the next instruction.

Wait for scanline number in range

The opcode for this instruction is 0x05. The lower 40 bits of the instruction has the upper and lower scanline numbers. DSB HW will wait for the scanline number to be within the programmed range of the line numbers before processing the next instruction.

Wait for scanline number out of range

The opcode for this instruction is 0x06. The lower 40 bits of the instruction has the upper and lower scanline numbers. DSB HW will wait for the scanline number to be out of the programmed range of the line numbers before processing the next instruction.

Generate Interrupt

The opcode for this instruction is 0x07. DSB HW, after decoding this instruction, will generate a interrupt when interrupt is enabled in **DSB_INTERRUPT** register and the IMR ad IER register bits are correctly programmed in **DE_PIPE_INTERRUPT** .

Indexed MMIO register writes

The opcode for this instruction is 0x09. The lower 32 bits of this instruction will have the number of the data dwords of the indexed MMIO writes. Bits 51:32 of this instruction will have the address offset.

- The data dwords are followed by this instructions.
- If the number of the data dwords is odd then the last dword of the instruction will be 0's to complete the 64 bit instruction. Example is shown below

Example of Indexed Register Writes with odd number of dwords

Poll Function

The opcode for this instruction is 0x0A. Lower 32 bits of the instruction will have the poll value to be compared and bits 51:32 have the offset of the register that needs to be polled on.

- SW must program the **DSB_POLLMASK** before this instruction is used. Poll mask will have the enable on each of the 32 bits that the data will be compared against.
- SW must also program the **DSB_POLLFUNC** register prior to using the poll function instruction. Poll function has to be enabled before using the poll function.
  - The default value of number of micro seconds to wait before a poll retry is set to 2us.
  - The default number of retries is set to 50 times before a timeout or poll fails
- SW can chose to add these two registers as part of DSB program itself before using the POLL instruction. But SW must add 5 NOOPs after MMIO writes instructions to these (**DSB_POLLMASK** and **DSB_POLLFUNC**) registers to allow some time for DSB engine to process the register writes to itself.

Special programming

The following transcoder registers need to special programming if they are part of the DSB program in the buffer. SW must follow the sequence listed below in the DSB program before adding programming of these registers.

1. Set the non-posted bit 8 to 1 in the **DSB_CTRL** register as part of the DSB program.
2. Add four No-Op instructions.
3. Add the transcoder register programming.
4. Set the non-posted bit 8 to 0 in the **DSB_CTRL** register.
5. Add four No-Op instructions
6. Add the rest of the programming (if any).

The list of these special registers is below.

DDI_BUF_CTL
TRANS_DDI_FUNC_CTL2
TRANS_DDI_FUNC_CTL
VIDEO_DIP_CTL
VIDEO_DIP_PPS_DATA_*
VIDEO_DIP_ADAPTIVE_SYNC_DATA_*
TRANS_CONF
TRANS_STEREO3D_CTL
TRANS_DPT_PAT
TRANS_SET_CONTEXT_LATENCY
TRANS_VRR_CTL
TRANS_VRR_FLIPLINE
TRANS_VRR_VMAXSHIFT
TRANS_VRR_VMAX
TRANS_VRR_VMIN
TRANS_VRR_VSYNC
TRANS_LINKN1
SRD_CTL
SRD_PERF_CNT
PSR_MASK
DP_COMP_CTL
DP_TP_CTL
PSR2_CTL

DSB Atomic Usage

The following is the framework for using DSB to program pipe and plane registers to atomically update (all update together for the same frame). DSB can also be used to update registers non-atomically or to update single resources that are self-atomic, with simpler sequences that don't require any wait for vblank.

For this atomic usage, transcoder timings must be programmed to create a window between start of undelayed vblank and delayed vblank. The typical requirement is a 100 microsecond window to provide enough time for DSB to program all the pipe and plane registers. Smaller values may be used for testing. Larger values may exceed required time for filling the display pipeline during vblank when using reduced blanking. ROUNDUP(desired window time/line time) = number of lines to program delayed vblank larger than undelayed vblank.

Fixed Refresh Rate

This requires VRR to be disabled.

Before enabling DSB, set bit 23=1b in the following register for the pipe and DSB to skip waits when PSR is entered.

Pipe A: DSB0 0x70BF0, DSB1 0x70CF0, DSB2 0x70DF0

Pipe B: DSB0 0x71BF0, DSB1 0x71CF0, DSB2 0x71DF0

Pipe C: DSB0 0x72BF0, DSB1 0x72CF0, DSB2 0x72DF0

Pipe E: DSB0 0x73BF0, DSB1 0x73CF0, DSB2 0x73DF0

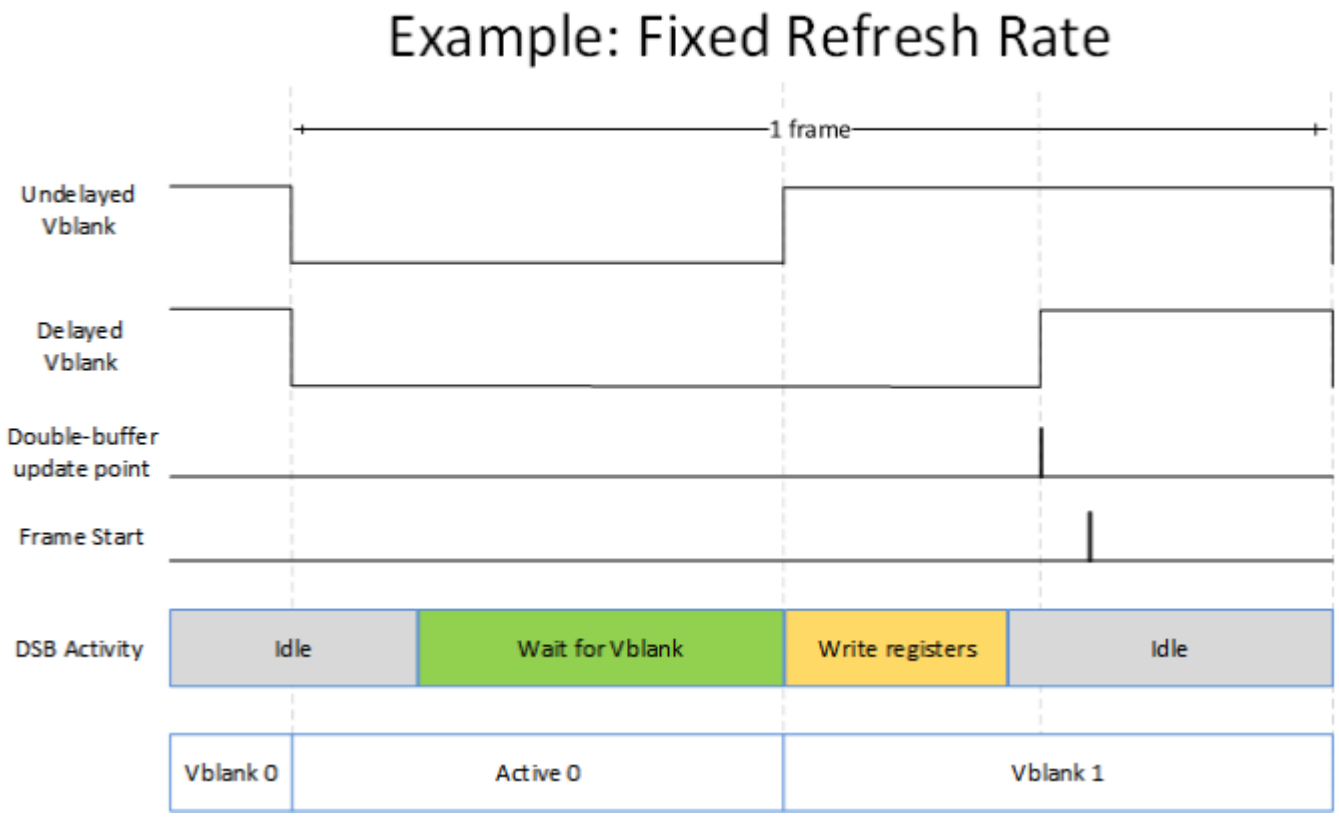
DSB will need to align instruction execution to the start of vblank. Either enable DSB_CTRL Wait for VBLANK or use the wait for vblank instruction.

Follow the General Programming Sequence of the DSB HW to setup and initiate DSB.

Use the following DSB instructions

1. If DSB_CTRL Wait for VBLANK not enabled, Wait for 1 vblank.
2. Write 1 to DSB_STATUS bit 16 to clear any previous indication that DSB was busy during delayed vblank.
3. Write pipe and plane registers to be updated for the next frame.
    - Depending on the registers to write, this can include register writes and indexed register writes.
    - Requirements for writing some registers in certain orders to arm them for double-buffer updates are still required.
4. Optional: Generate Interrupt

After DSB completes, found through interrupt or polling on DSB status, read DSB_STATUS bit 16 to find if delayed vblank started before DSB finished. If it did, then there was an error and the pipe and plane programming may not be complete. Software may log the error and attempt recovery.



Variable Refresh Rate

This requires VRR with push bit mode.

Before enabling VRR, set bit 31 in the following register for the transcoder attached to this pipe to enable VRR safe window generation.

Transcoder A: 0x420C0

Transcoder B: 0x420C4

Transcoder C: 0x420C8

Transcoder D: 0x420D8

Before enabling DSB, set bits 23=1b, 15:14=11b, bits 7:6=11b in the following register for the pipe and DSB to enable VRR safe window to be used instead of vblank and to skip waits when PSR is entered.

Pipe A: DSB0 0x70BF0, DSB1 0x70CF0, DSB2 0x70DF0

Pipe B: DSB0 0x71BF0, DSB1 0x71CF0, DSB2 0x71DF0

Pipe C: DSB0 0x72BF0, DSB1 0x72CF0, DSB2 0x72DF0

Pipe E: DSB0 0x73BF0, DSB1 0x73CF0, DSB2 0x73DF0

DSB will need to align instruction execution to the VRR safe window. Either enable DSB_CTRL Wait for VBLANK during DSB setup or use the wait for vblank instruction.

Follow the General Programming Sequence of the DSB HW to setup and initiate DSB.

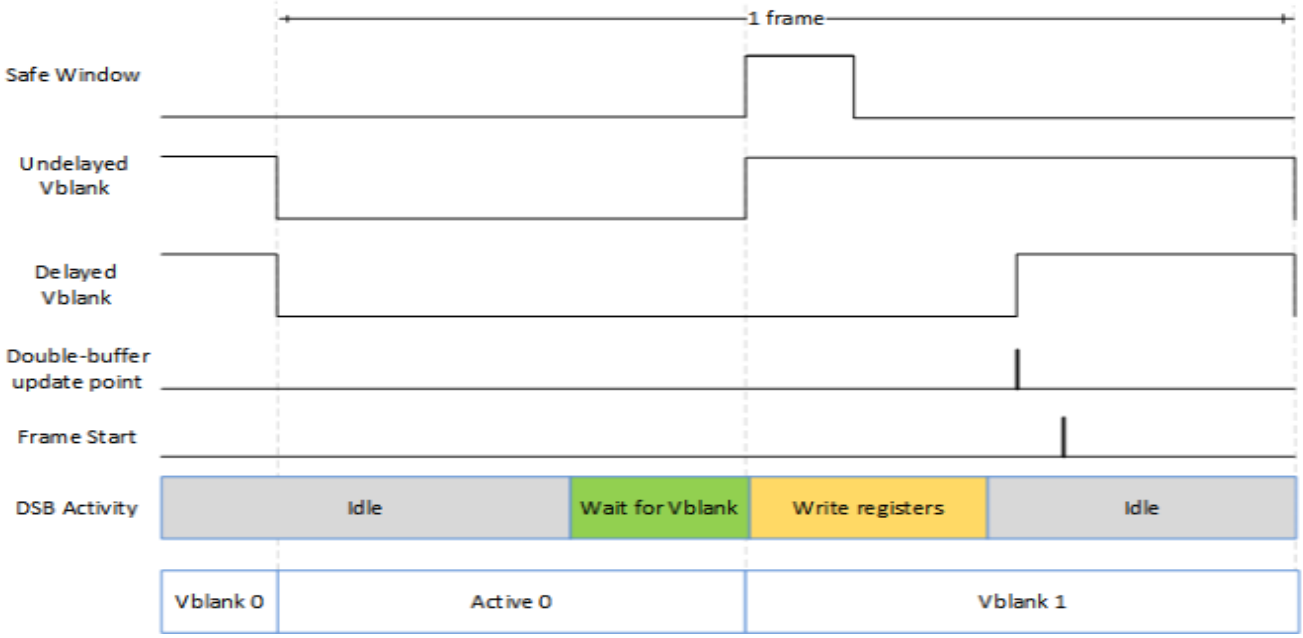
Use the following DSB instructions

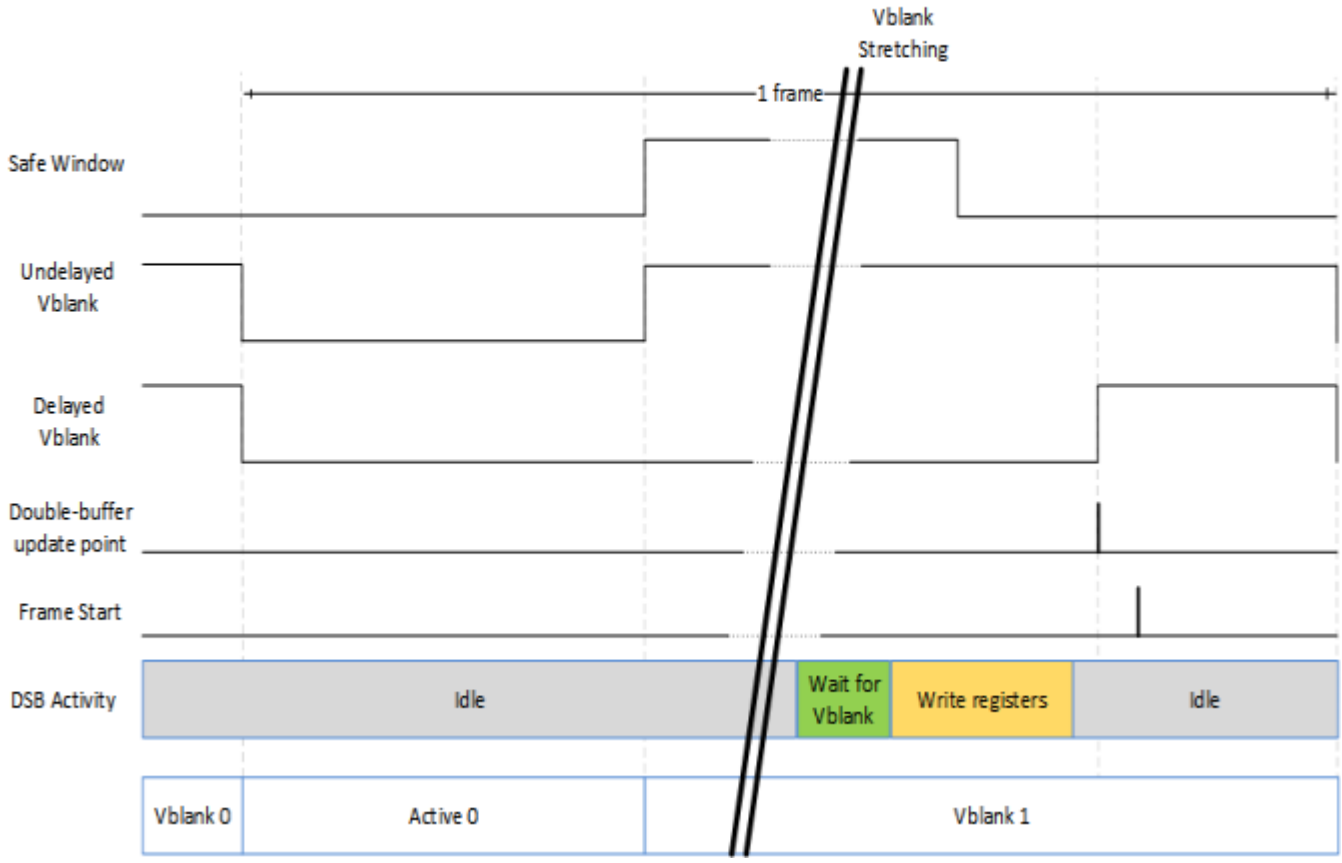
1. If DSB_CTRL Wait for VBLANK not enabled, Wait for 1 vblank.
2. Write 1 to DSB_STATUS bit 16 to clear any previous indication that DSB was busy during delayed vblank.
3. Write 1 to transcoder push bit*. This step can be done here or in step 5. Initiating push at this point will allow the vblank to end sooner, but is different from the non-DSB programming flow that does push at the end.
4. Write pipe and plane registers to be updated for the next frame.
    - Depending on the registers to write, this can include register writes and indexed register writes.
    - Requirements for writing some registers in certain orders to arm them for double-buffer updates are still required.
5. Write 1 to transcoder push bit* if not done in earlier step.
6. Optional: Generate Interrupt

After DSB completes, found through interrupt or polling on DSB status, read DSB_STATUS bit 16 to find if delayed vblank started before DSB finished. If it did, then there was an error and the pipe and plane programming may not be complete. Software may log the error and attempt recovery.

*If driver knows that push is already guaranteed to be set outside of this DSB, such as by another DSB running in parallel, then this push can optionally be skipped. This requires very careful sequencing to ensure that this DSB does not get out of alignment with whatever is issuing the push.

Example: VRR – DSB Wait Starts Before Vblank





Adding Dynamic Metadata

If dynamic metadata will be sent just once, then it can be programmed together with the pipe and plane registers in the previous sequences.

Color Space Conversion

CSC_COEFF

CSC COEFFICIENT FORMAT

CSC_PREOFF

CSC_POSTOFF

CSC_MODE

OUTPUT_CSC_COEFF

OUTPUT_CSC_PREOFF

OUTPUT_CSC_POSTOFF

The high color channel is the most significant bits of the color. The low color channel is the least significant bits of the color. The medium color channel is the bits between high and low. For example: In

RGB modes Red is in the High channel, Green in Medium, and Blue in Low. In YUV modes, V is in the High channel, Y in Medium, and U in Low.

The color space conversion registers are double buffered and are updated on the start of vertical blank following a write to the CSC Mode register for the respective pipe.

The matrix equations are as follows:

OutputHigh = (CoefficientRY * InputHigh) + (CoefficientGY * InputMedium) + (CoefficientBY * InputLow)

OutputMedium = (CoefficientRU * InputHigh) + (CoefficientGU * InputMedium) + (CoefficientBU * InputLow)

OutputLow = (CoefficientRV * InputHigh) + (CoefficientGV * InputMedium) + (CoefficientBV * InputLow)

Example programming for RGB to YUV is in the following table:

The input is RGB on high, medium, and low channels respectively and the desired YUV output is VYU on high, medium, and low channels respectively.

Program CSC_MODE to put gamma before CSC.

Program the CSC Post-Offsets to +1/2, +1/16, and +1/2 for high, medium, and low channels respectively.

The coefficients and pre and post offsets can be scaled if desired.

Pipe 3D LUT

The 3D LUT is a pixel modification function which resides in the post blend color processing section of the display pipeline. It is used to apply non-linear transforms on each color component on a per pixel basis. Our LUT implementation uses a 17x17x17 three dimensional matrix of color points, with each point holding a 30 bit pixel value (10 bpc).

3D LUT functionality is supported only in pipe A and pipe B.

LUT_3D_CTL

LUT_3D_INDEX

LUT_3D_DATA

Programming

Enabling 3D LUT

Software should follow the sequence below.

1. Check if the "New LUT Ready" bit is clear. If set, software must wait till the bit is clear. LUT entries must not be change the LUT entries when the "New LUT Ready" is set.
2. Load the desired 3D LUT entries.
3. Set the "Enable" and the "New LUT Ready" bits.

The LUT buffer is double buffered. When 3D LUT functionality is enabled, the hardware observes the "New LUT Ready" bit on every vblank start. If the "New LUT Ready" bit is set, hardware loads the LUT entries in to its working RAM and clears the bit. The 3D LUT functionality works with programmed LUT values in the following frames until it gets disabled. When the "New LUT Ready" bit is clear, the software is allowed to modify the LUT entries.

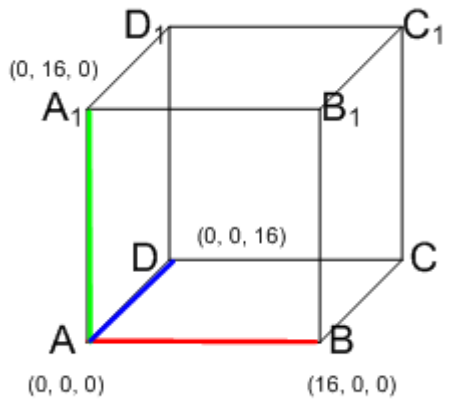
Disabling 3D LUT

1. Clear the "Enable" bit to '0'.

Programming 3D LUT Entries

The LUT array is accessed by an index/data register pair. The index register is read/writable and auto-increments after each read/write to the data register. Write '0' into the index register, followed by 4913 LUT entry writes to the data register.

Each LUT 3D entry is 30 bits and programmed as R10G10B10 (msb... lsb) value in the LUT_3D_DATA register. Since 10 bit values are used for all 17 points, the max value programmed is limited to 1023. A 1:1 mapping should use [0, 64, 128, 192, 256, 320, 384, 448, 512, 576, 640, 704, 768, 832, 896, 960, 1023].



The LUT entries should start at A and end at C_1 following the sequence specified below.

```
Iterate on Red axis from 0 - 16 {
 Iterate on Green axis 0 - 16 {
 Iterate on Blue axis 0 - 16 {
program 3D LUT entry
}
 }
 }
```

Pipe DPST

Registers

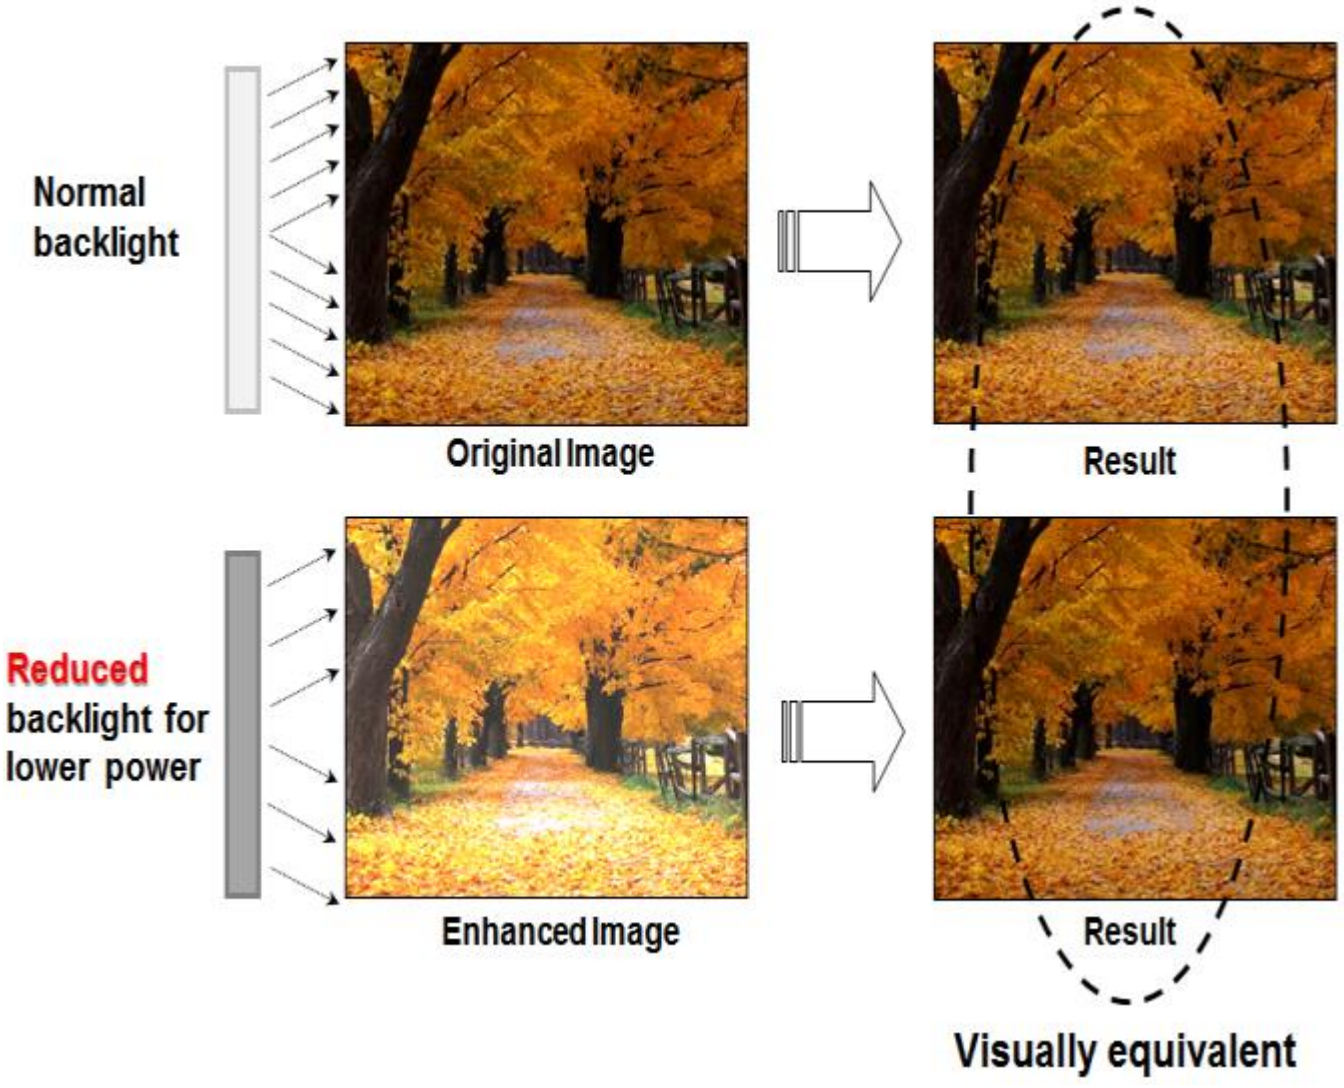
DPST_CTL

DPST_GUARD

DPST_BIN

Overview

Display Power Savings Technology (DPST) achieves significant platform average power savings by dynamically decreasing the display backlight brightness, while increasing the pixel values in the displayed image by a corresponding factor. The goal of DPST is to provide equivalent end-user-perceived image quality at a decreased backlight power level.



DPST generates statistics (histogram) for each image frame that is sent to the display. These statistics are used to determine if, and by how much, the backlight level can be reduced, saving backlight power. In order to maintain the same image brightness, the image pixel values are increased by an amount related to the backlight level reduction.

DPST is composed of three blocks.

Histogram Block

The hardware histogram block generates image statistics based on the pixel stream input. These statistics are used by the Processing block to determine how much the backlight level can be reduced.

The histogram block has the following requirements.

- Generate a histogram for each frame of display data
  - The histogram is generated based on the brightness of each pixel.
    - DPST_CTL Histogram Mode Select selects how the brightness is determined; either HSV max(RGB_{in}), or the luma after converting RGB_{in} to YUV.
  - The histogram is composed of 32 bins with each bin covering a range of 8 values for 8 bit pixel component values. The first bin covers the values 0 thru 7.
    - If the pixel component values use more than 8 bits, the most significant 8 bits are used to form the histogram.
  - Each bin value has enough bits to count every pixel within an image.
  - Enabled by DPST_CTL IE Histogram Enable
- Two sets of histograms
  - The histogram currently being generated and a saved histogram from a previous frame.
  - The current histogram is moved to the saved histogram at the end of a frame in which a threshold event occurs.
  - Each bin of the saved histogram is readable by software.
  - Clear DPST_CTL Bin Register Function Select to TC
  - Wait for vertical blank for switch to TC mode, can skip if step 1 was done more than 1 vblank previously
  - Set DPST_CTL Bin Register Index to 0
  - Read DPST_BIN
  - If DPST_BIN Busy Bit is 1, go to step 3
  - Store DPST_BIN Data
  - Go to step 4 until all 32 bins are read
- Threshold register for comparing the histogram of the current frame to the histogram of the saved frame.
  - If any bin in the current histogram differs from the same bin in the saved histogram by more than the value in DPST_GUARD Threshold Guardband, then a threshold event is generated at the start of vertical blank.
  - DPST_GUARD Guardband Interrupt Delay specifies the number of consecutive frames the threshold must be exceeded before generating a threshold event.
    - This allows filtering out momentary variations from generating a threshold event.
  - DPST_GUARD Histogram Interrupt Enable enables the threshold event interrupt.
  - DPST_GUARD Histogram Event Status is a sticky bit that is set with the interrupt and must be cleared to receive more histogram events.

Enhancement Block

The hardware enhancement block adjusts the pixel values sent to the display, compensating for the brightness loss due to lowering of the display backlight level.

The enhancement block has the following requirements.

- Located after the histogram block
- Enabled by DPST_CTL IE Modification Table Enable
- Find the enhancement factor from a Look Up Table (LUT) with 33 entries
    - Switch (DPST_CTL Enhancement mode)
        - Case Direct: LUT address = most significant bits of RGB_{input}
        - Case Multiplicative: LUT address = most significant bits of HSV max(RGB_{input})
        - Case Additive: LUT address = most significant bits of Y channel after converting RGB_{input} to YUV
    - DPST_CTL IE Table Value Format selects if the enhancement factor is a 1 integer and 9 fractional bits format, or a 2 integer and 8 fractional bits format.
        - The 2 integer and 8 fractional bits format allows for brightness increases nearly to 4x, but with reduced precision.
    - The final enhancement factor is derived by interpolating between the addressed LUT entry and the next entry, using the lower bits of the input.
    - Each entry of the LUT is programmable by software.
    - Set DPST_CTL Bin Register Function Select to IE
    - Wait for vertical blank for switch to IE mode, can skip if step 1 was done more than 1 vblank previously
    - Set DPST_CTL Bin Register Index to 0
    - Write enhancement factor to DPST_BIN Data
    - Go to step 4 until all 33 entries are written
        - The IE values are double-buffered and will update on the next start of pipe vblank. The values are not atomically updated or tied into the global double buffering control (disable/stall), so if programming straddles the pipe vblank start, some values will update in the upcoming frame and some in the frame after that.
- The enhancement factor modifies each input pixel component value with the method selected by DPST_CTL Enhancement Mode.
    - Direct lookup mode replaces the input pixel value with the enhancement factor.
    - Additive mode increases the input pixel value by the enhancement factor.
    - Multiplicative mode multiplies the input pixel value by the enhancement factor.

Processing Block

The software processing block responds to the histogram threshold interrupts, determines how much the backlight level can be reduced, then sets the backlight level and programs the Enhancement block.

The Processing block has the following requirements.

- Enable or disable the hardware blocks based on OS and user control inputs.
- Respond to the histogram threshold interrupts by reading the histogram and calculating a new backlight level based on statistics from the histogram.
    - The calculation is proprietary. In general, darker images will allow greater backlight reduction, and increased power savings.
    - The aggressiveness of backlight reduction can be controlled by the OS and user.
    - The final backlight reduction amount must be combined with backlight level requirements set by the OS, applications, and other power saving technologies.
- Program the Enhancement block to compensate for the brightness loss due to reducing the backlight level.
    - Because the maximum RGB component value is limited, not all pixel values can be perfectly compensated.
    - The number of pixel values which cannot be perfectly compensated is a function of the aggressiveness level.
- Phase-in the backlight level change and pixel enhancement gradually, in order to avoid flickering artifacts.

Pipe Palette and Gamma

The display palette provides a means to correct the gamma of an image stored in a frame buffer to match the gamma of the monitor or presentation device. Additionally, the display palette provide a method for converting indexed data values to color values for VGA and 8-bpp indexed display modes. The display palette is located after the plane blender. Using the individual plane gamma enables, the blended pixels can go through or bypass the palette on a pixel by pixel basis.

If any gamma value to be programmed exceeds the maximum allowable value in the associated gamma register, then the programmed value must be clamped to the maximum allowable value.

Programming Modes

The display palette can be accessed through multiple methods and operate in one of four different modes as follows.

8 bit legacy palette/gamma mode:

This provides a palette mode for indexed pixel data formats (VGA and primary plane 8 bpp) and gamma correction for legacy programming requirements.

All input values are clamped to the 0.0 to 1.0 range before the palette/gamma calculation. It is not recommended to use legacy palette mode with extended range formats.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the 256 palette/gamma entries. The 256 entries are stored in the legacy palette with 8 bits per color in a 0.8 format with 0 integer and 8 fractional bits.

The legacy palette is programmable through both MMIO and VGA I/O registers. Through VGA I/O, the palette can look as though there are only 6 bits per color component, depending on programming of other VGA I/O registers.

Direct lookup (10 bit) gamma mode:

This provides the highest quality gamma for pixel data formats of 30 bits per pixel or less.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the first 1024 gamma entries. The first 1024 entries are stored in the precision palette with 10 bits per color in a 0.10 format with 0 integer and 10 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 1024th and 1025th gamma entries to create the result value. The 1025th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For input values greater than or equal to 3.0 and less than 7.0, the input value is used to linearly interpolate between the 1025th and 1026th gamma entries to create the result value. The 1026th entry is stored in the PAL_EXT2_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

All input values are clamped to the greater than -7.0 and less than 7.0 range before the gamma calculation.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

Interpolated gamma mode:

This mode uses up to 515 gamma entries and the gamma output gets computed through interpolation between the neighboring LUT entries.

The gamma correction curve is represented by specifying a set of gamma entry reference points spaced equally along the curve for values between -1 and 1. For extended values there is an extended gamma entry reference point at the maximum allowed input value.

For input values greater than or equal to 0 and less than 1.0, the input value is used to linearly interpolate between two adjacent points of the first 513 gamma entries to create the result value. The first 512 entries are stored in the precision palette with 16 bits per color in a 0.16 format with 0 integer and 16 fractional bits (upper 10 bits in odd indexes, lower 6 bits in even indexes). The 513th entry is stored in the PAL_GC_MAX register with 17 bits per color in a 1.16 format with 1 integer and 16 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 513th and 514th gamma entries to create the result value. The 514th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For input values greater than or equal to 3.0 and less than 7.0, the input value is used to linearly interpolate between the 514th and 515th gamma entries to create the result value. The 515th entry is stored in the PAL_EXT2_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

All input values are clamped to the greater than -7.0 and less than 7.0 range before the gamma calculation.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

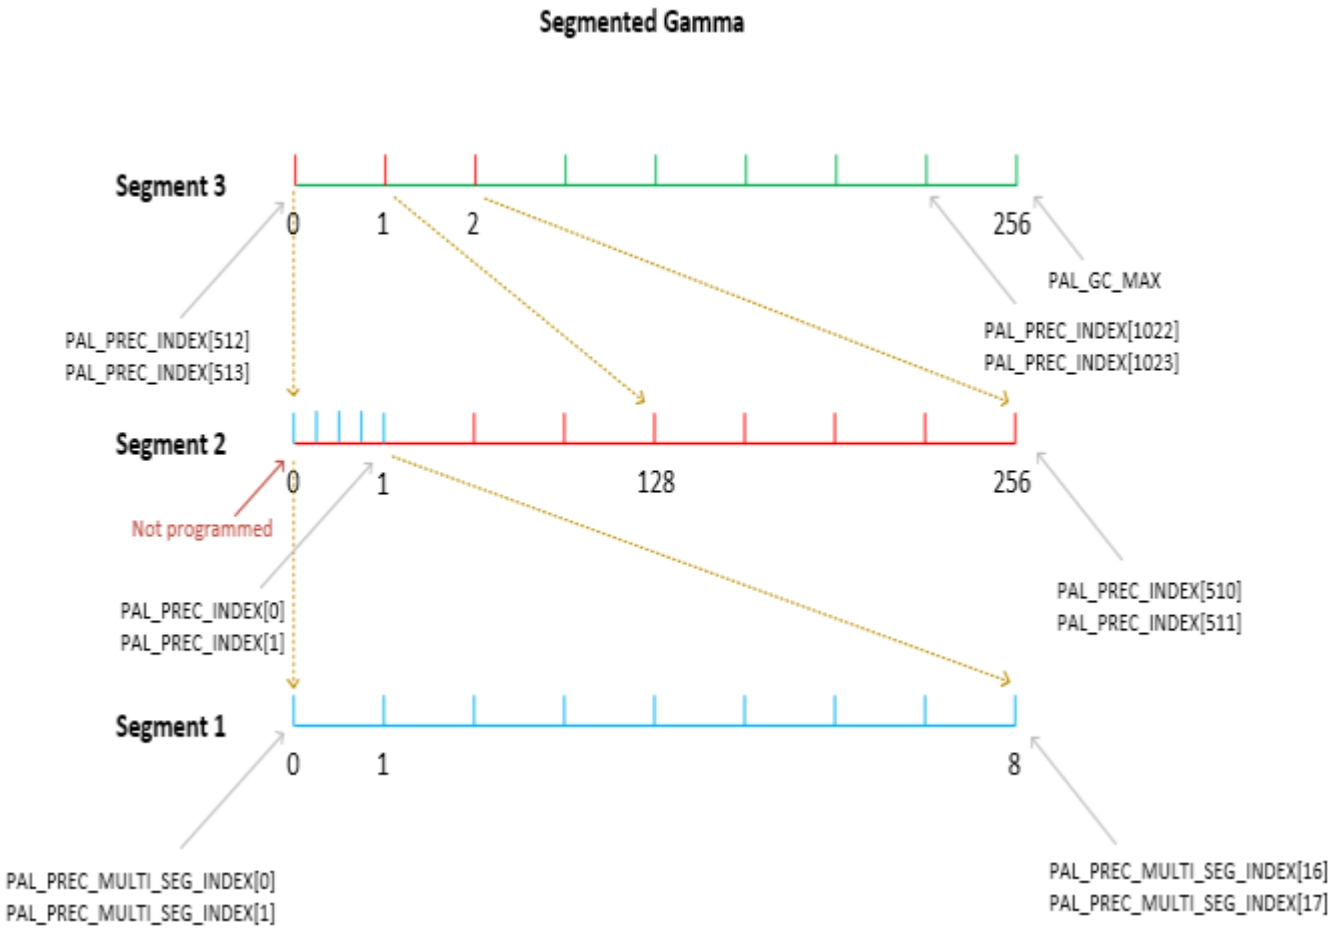
To program the gamma correction entries, calculate the desired gamma curve for inputs from 0 to 3.0. The curve must be flat or increasing, never decreasing. For inputs of 0 to 1.0, multiply the input value by 512 to find the gamma entry number, then store the desired gamma result in that entry. For inputs greater than 1.0 and less than or equal to 3.0, store the result for an input of 3.0 in the 514th gamma entry.

Multi-segmented interpolated gamma mode:

This provides the highest quality gamma for HDR with three segments, each addressing different parts of the gamma curve. The gamma output gets computed through interpolation between the neighboring LUT entries.

The gamma correction curve is represented by specifying a set of gamma entry reference points, spaced equally within each segment, along the curve for values between -1 and 1. For extended values there is an extended gamma entry reference point at the maximum allowed input value.

All input values are clamped to the greater than -7.0 and less than 7.0 range before the gamma calculation.



For input values greater than or equal to 0 and less than 1.0, the input value is used to linearly interpolate between two adjacent points of the gamma entries to create the result value. The gamma entries in all segments are stored in the precision palette with 16 bits per color in a 0.16 format with 0 integer and 16 fractional bits (upper 10 bits in odd indexes, lower 6 bits in even indexes). The 513th entry is stored in the PAL_GC_MAX register with 17 bits per color in a 1.16 format with 1 integer and 16 fractional bits.

For input values greater than 1.0 and less than 3.0, the input value is used to linearly interpolate between the 513th and 514th gamma entries to create the result value. The 514th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits. For input values greater than or equal to 3.0 and less than 7.0, the input value is used to linearly interpolate between the 514th and 515th gamma entries to create the result value. The 515th entry is stored in the PAL_EXT2_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

To program the gamma correction entries, calculate the desired gamma curve for inputs from 0 to 7.0. The curve must be flat or increasing, never decreasing. For inputs of 0 to 1.0, program the gamma segments 1, 2 and 3. For inputs greater than 1.0 and less than or equal to 3.0, store the result for an input of 3.0 in the 514th gamma entry.

The Segment 1 or the super fine segment has 9 entries covering the input range from 0 to 1/(128*256) => [0, 1/(8* 128*256), 2/(8* 128*256) ... 1/(128*256)] . The 9 entries of Segment 1 gamma values gets programmed using the PAL_PREC_MULTI_SEG* registers ranging from index 0 to index 17.

The Segment 2 or the fine segment has 257 entries covering the input range from 0 to 1/128 => [0, 1/(128*256), 2/(128*256) ... 1/128]. The Segment 2 gamma values gets programmed using the PAL_PREC* registers ranging from index 0 to index 510. The Segment 2 zero value is implied in hardware and is not explicitly programmed by software. Segment 2 first value is programmed in PAL_PREC* index 0 as shown in the figure above.

The Segment 3 or the coarse segment has 257 entries covering the input range from 0 to 1 => [0, 1/256, ... 255/256, 1.0]. The first 256 entries of Segment 3 gamma values gets programmed using the PAL_PREC* registers ranging from index 512 to index 1023. The 257th value (1.0) is programmed in PAL_GC_MAX register.

Pixel Passthrough Operation

For modes of operation where the input image CRC needs to match the output image CRC (i.e. the pixels need to flow through the pixel pipe unmodified from frame buffer to the port), the following programming needs to be done:

1. Use only a single Plane with no cursor (**CUR_CTL**)
2. Use a fixed point, non-planar pixel format without Alpha (**PLANE_CTL**). Make sure the frame buffer format matches the port output format

3. Disable all color correction (i.e. CSC, Gamma, etc), Lace, Scaling, compression and dithering within the Plane and Pipe. See the other sub-sections of the Pipe/Planes chapters for more details:
    1. Universal Plane
    2. Color Space Conversion
    3. Pipe Color Gamut Enhancement
    4. Pipe Palette and Gamma
    5. Pipe LDPST
    6. Pipe 3D LUT
    7. Pipe DPST
    8. Pipe Scaler
    9. DSC (Display Stream Compression)
4. If the Plane that is being used (i.e. enabled) is an HDR Plane, then the HDR Mode bit within **PIPE_MISC** must be set. Otherwise, the HDR Mode bit of PIPE_MISC must be **cleared**.
5. Disable (i.e. truncate) Pixel Rounding (**PIPE_MISC**)

Pipe Scaler

Each scaler has its own set of registers.

Scaler
PS_PWR_GATE
PS_WIN_POS
PS_WIN_SZ
PS_CTRL
PS_VSCALE
PS_HSCALE
PS_VPHASE
PS_HPHASE
PS_ECC_STAT
PS_ADAPTIVE_CTRL
PS_COEF_INDEX
PS_COEF_DATA
SCALER_COEFFICIENT_FORMAT
PS_PROG_HSCALE PS_PROG_VSCALE

Scaler Programmed Coefficients

Two sets of programmed coefficients are available for each scaler. The horizontal filter and vertical filter can be configured individually to use one of these 2 sets. When used for YUV planar format plane scaling, the Y and UV scalers can be configured individually to use one of the 2 sets. Scaler coefficients

are accessed through their respective index and data registers following the mapping shown below. The coefficients must be programmed in the SCALER_COEFFICIENT_FORMAT.

17 phase of 7 taps requires 119 coefficients in 60 dwords per set. The letter represents the filter tap (D is the center tap) and the number represents the coefficient set for a phase (0-16).

Coefficient Set		
Index Value	**Data Value Coefficient 2**	**Data Value Coefficient 1**
00h	B0	A0
01h	D0	C0
02h	F0	E0
03h	A1	G0
04h	C1	B1
...	...	...
38h	B16	A16
39h	D16	C16
3Ah	F16	E16
3Bh	Reserved	G16

Nearest-neighbor scaling (Integer scaling ratios)

Nearest neighbor scaling can be used to maintain the rendering intent of some classic games in integer upscaling scenarios. For enabling nearest-neighbor scaling, the scaler must be set to use "programmed" mode with the center tap (Dxx) values set to 1 and all other values set to 0. The following coefficients values must be used with the coefficients programmed in the SCALER_COEFFICIENT_FORMAT.

Coefficient Set		
Index Value	**Data Value Coefficient 2**	**Data Value Coefficient 1**
00h	B0 = 0	A0 = 0
01h	D0 = 1	C0 = 0
02h	F0 = 0	E0 = 0
03h	A1 = 0	G0 = 0
04h	C1 = 0	B1 = 0
...	...	...
38h	B16 = 0	A16 = 0
39h	D16 = 1	C16 = 0
3Ah	F16 = 0	E16 = 0
3Bh	Reserved	G16 = 0

Register Double Buffering

Prior to D11, the Scaler has the following double buffer trigger points:

1. When the Pipe is disabled:
    a. Any write to the PS_CTRL register (will refer to this as Control DB trigger)
    b. Any write to the PS_WINSZ register (will refer to this as WinSize DB trigger)
2. When the Pipe is enabled:
    a. For registers that are part of the Control DB trigger group, the DB trigger point is on the rising edge of V. Blank when double buffering is armed
    b. For registers that are part of the WinSize DB trigger group, the DB trigger point is after the Frame Start when double buffering is armed

From D11 and onwards, the Scaler has the following double buffer trigger points:

1. When the Pipe is disabled:
    a. Any write to the PS_CTRL register (Control DB trigger)
    b. Any write to the PS_WINSZ register (WinSize DB trigger)
2. When the Pipe is enabled, the DB trigger point is on the rising edge of V. Blank when double buffering is armed and double buffering is allowed (Allow Double Buffer Update Disable = 1 in PS_CTRL)

When the Pipe is enabled, any write to the PS_WINSZ will arm the double buffering for the Scaler registers.

Once double buffering is armed, the disarming point is dependent on the Display generation.

- Prior to D11: Double buffering is disarmed on the next WinSize DB trigger (i.e. after Frame Start)
- D11+ : Double buffering is disarmed on the next rising edge of V. Blank where double buffering is allowed

As implied above, the double buffering for each of the Scaler registers is dependent on the trigger group it is within (i.e. Control or WinSize).

Register	DB Trigger
PS_PWR_GATE	Control
PS_CTRL	Control
PS_VPHASE	WinSize
PS_HPHASE	WinSize
PS_ADAPTIVE_SET_*_CTRL	WinSize
PS_WINPOS	WinSize
PS_WINSZ	WinSize

Note that the Programmable Coefficient sets accessed through the PS_COEF_SET_*_INDEX and PS_COEF_SET_*_DATA registers are on the Control DB trigger.

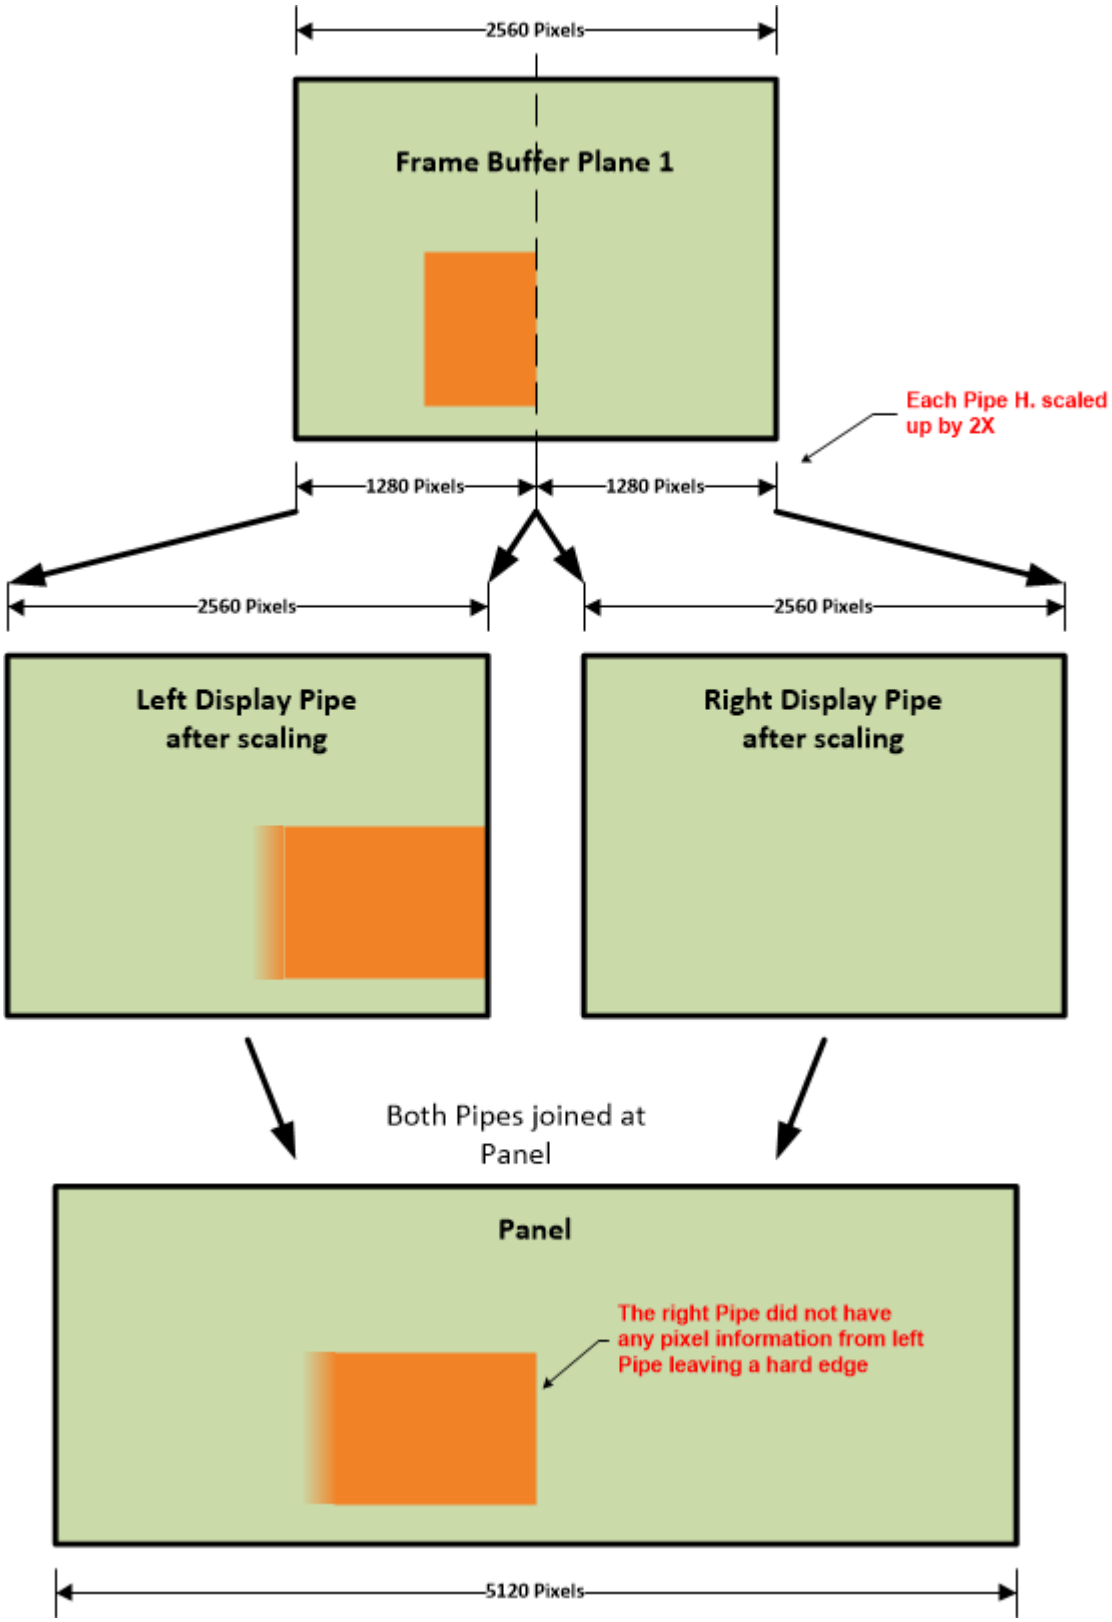
Programming Sequence

The below sequence should be followed when programming the Scaler to ensure proper double buffering:

- Configure the Scaler's Programmable Coefficient sets through PS_COEF_SET_*_INDEX and PS_COEF_SET_*_DATA registers, if using Programmable Coefficients
- Configure power gating control of the Scaler SSA's (PS_PWR_GATE), if the Scaler is not already enabled
- Enable and/or configure Scaler (PS_CTRL), if needed
    - If the Scaler is not already enabled, the Scaler will begin the process of powering up the Scaler SSA's
    - Software doesn't have to write to this register to enable Control DB trigger registers (i.e. Programmable Coefficient sets) if the Scaler and Pipe are both enabled
- Configure initial phases (PS_*PHASE), adaptive control (PS_ADAPTIVE_SET_*_CTRL), and window position (PS_WINPOS), if needed
- Configure/write to the PS_WINSZ
    - For pre-D11 products, the write to this register should only be done outside of the V. Blank regime if the Pipe is enabled. There are no restrictions for D11+ products
    - If Software has changed any PS_* register programming and the Pipe is enabled, then Software has to write to this register regardless of whether the value is changing, or not.

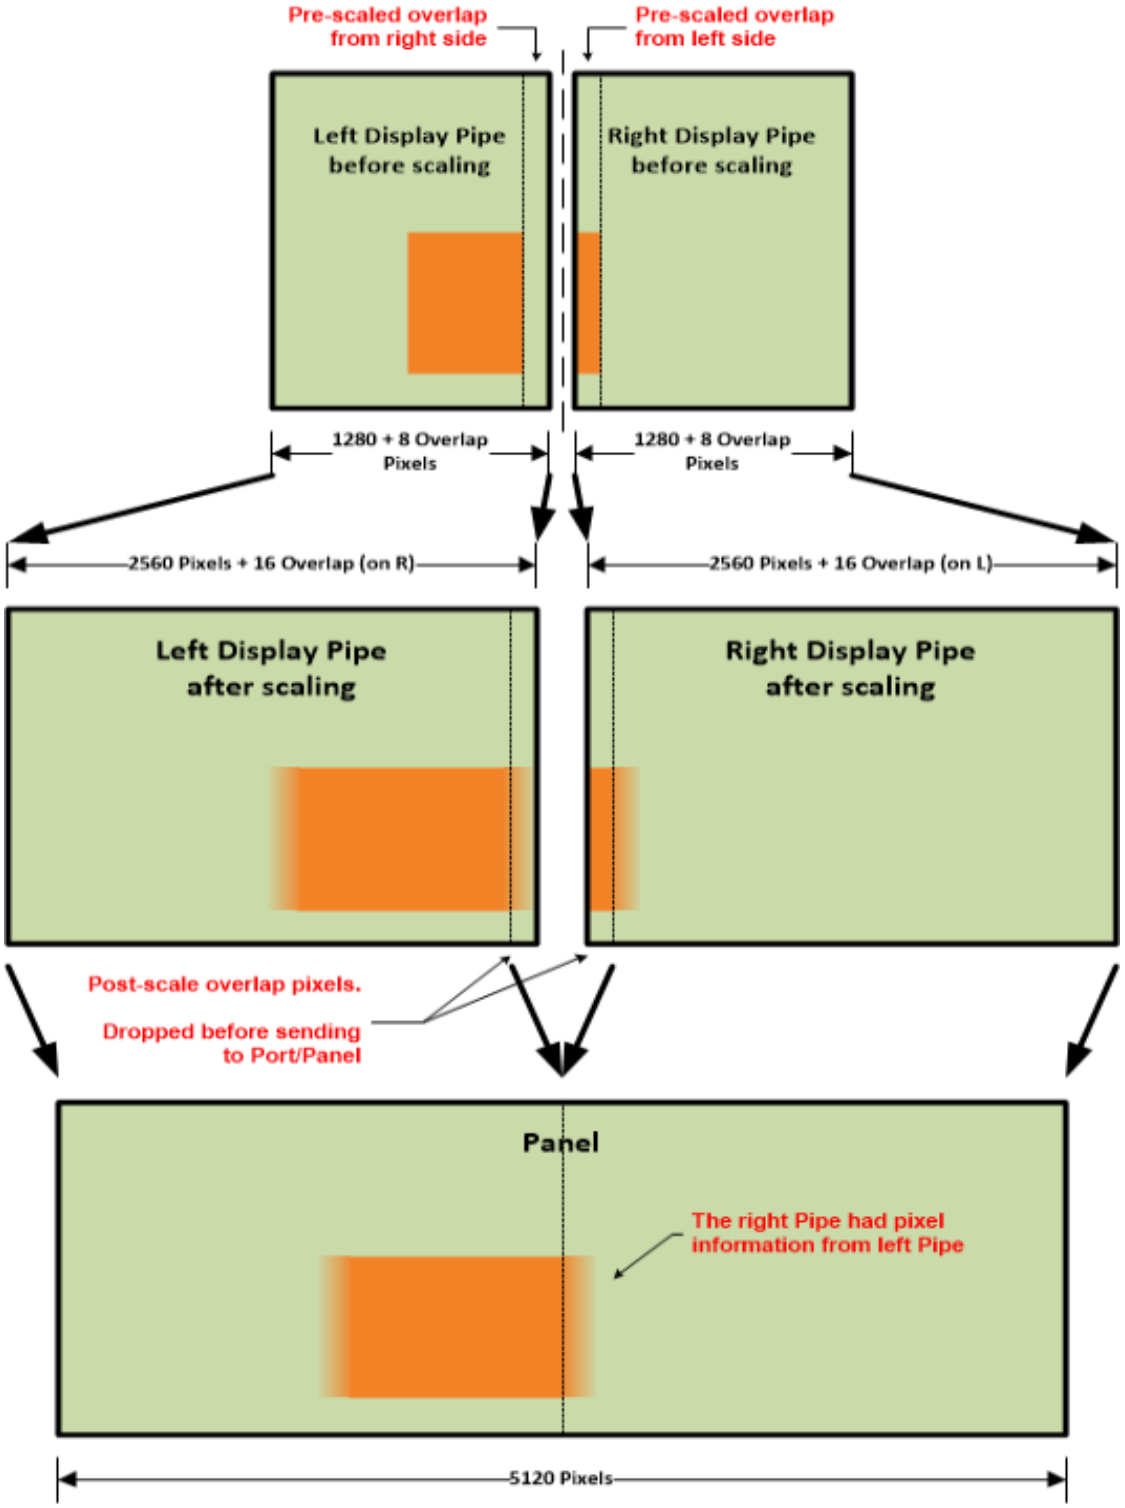
Tiled Scaling (Seam Removal)

There are certain usage cases where an image from memory will be horizontally split across two Pipes, scaled up, and then joined at the Port/Panel. When the image is being horizontally scaled up across the seam of the split image if the Scalers within each Pipe do not have some additional pixels from the other Pipe's image, then an artifact at the seam can occur.



2560 Pixels
Frame Buffer Plane 1
Each Pipe H. scaled up by 2X
1280 Pixels
1280 Pixels
2560 Pixels
2560 Pixels
Left Display Pipe after scaling
Right Display Pipe after scaling
Both Pipes joined at Panel
Panel
The right Pipe did not have any pixel information from left Pipe leaving a hard edge
5120 Pixels

By adding some overlapping pixels of the split image around the seam, the Scalers within each Pipe will be able to correctly filter across the seam. At the end of the Pipe (before the image is delivered to the Port) the post-scaled overlap pixels will be dropped.



To perform the cross seam scaling, Software will be responsible for the following:

- It will calculate the pre and post scale excesses needed for each Pipe
- It will include the pre-scale excess within the pre-scaled Horizontal image sizes (e.g. the Horizontal Source Size of the PIPE_SRCSZ register)
- It will include the post-scale excess within the Scaler's Window Size register (PS_WIN_SZ)
- It will program the post-scale excess within the PIPE_SEAM_EXCESS register
- It will program the Horizontal Active size at the transcoder (TRANS_HTOTAL) to be the Panel width
    - This should **not** include any seam pixels

The following sections will discuss how Software will determine the pre/post excess sizes and the initial phase needed for the Scaler processing the right side image.

Location of Seam and Splitting Source Image

When the location of an image in memory is going to cross the seam between the two Pipes, then the PLANE_SIZE, PLANE_POS, and PLANE_OFFSET registers of the Planes carrying the image (one within each Pipe) will determine how that image in memory is split across the two Pipes.

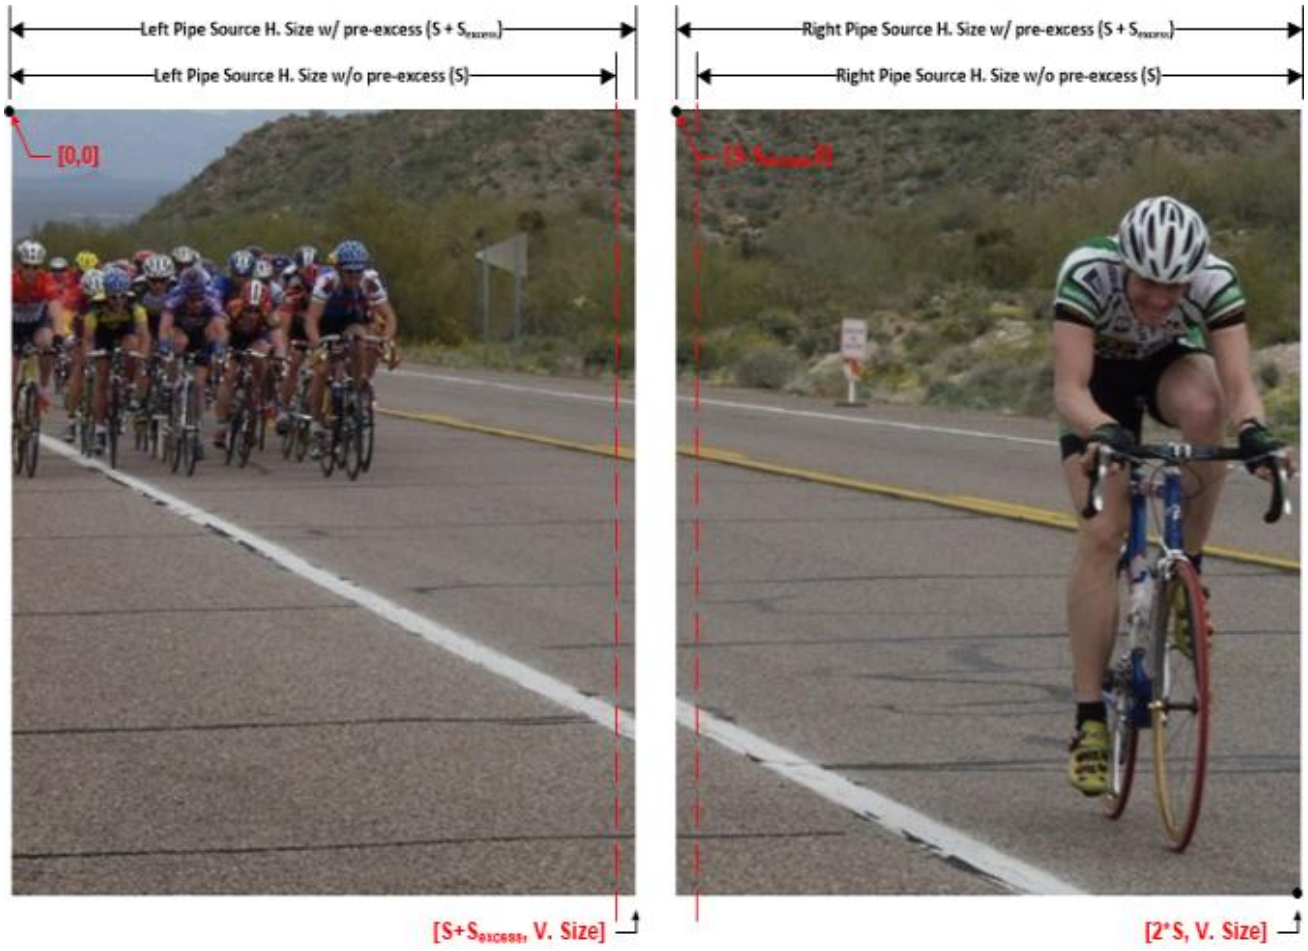
Seam Location

The location of the seam is relative to the left or right side of the Pipe Source Size window where the horizontal Pipe Source Size will include the pre-scaled excess (a.k.a. Source Excess, or S_{excess})

H. Pipe Source Size = Target H. Pipe Source Size (S) + Source Excess (S_{excess})

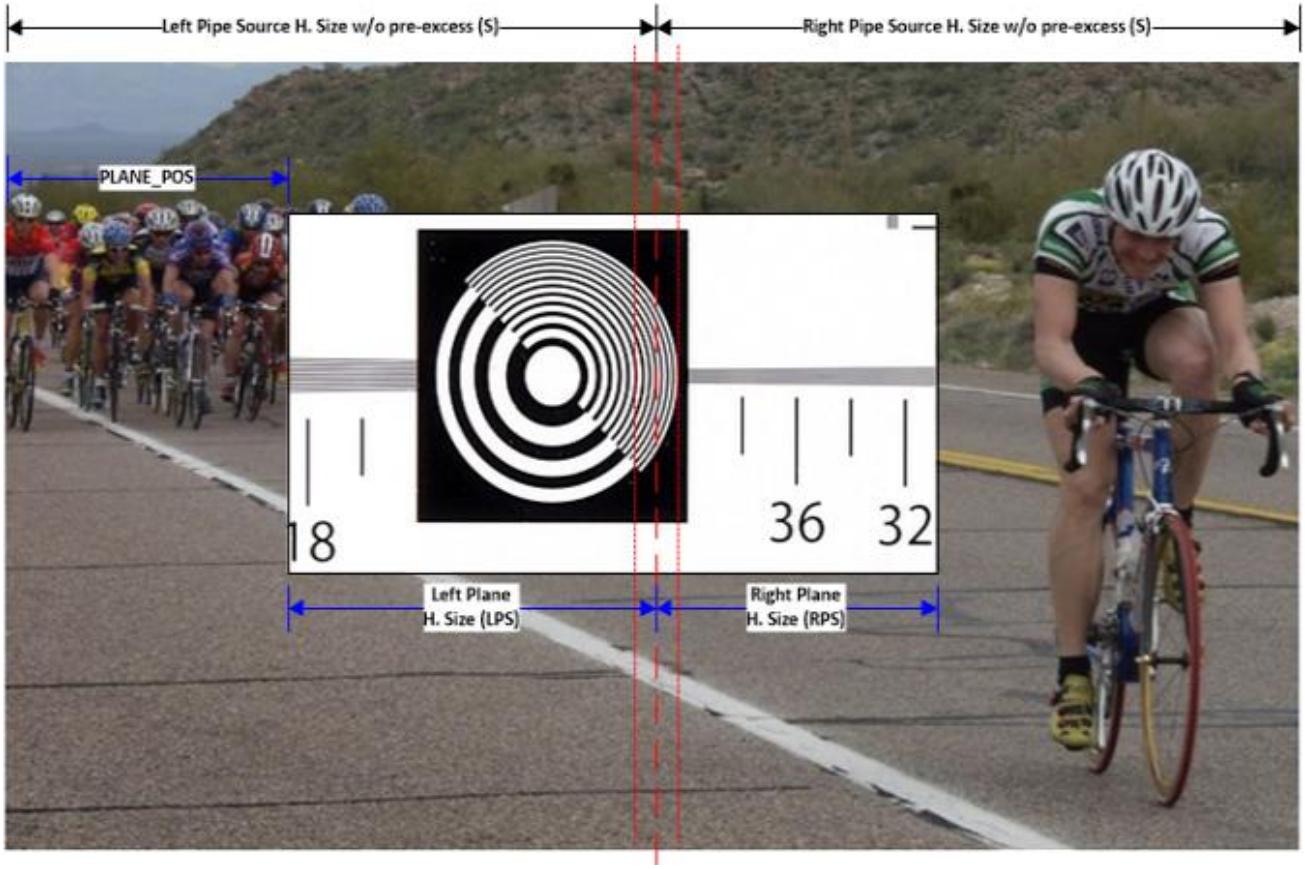
For the left-side Pipe, the seam will be located on the right-side of its source window, and for the right-side Pipe, the seam will be located on the left-side of its source window.

[0,0]
Seam
[2*S, V. Size]



Note that this discussion assumes symmetric horizontal Pipe Source Sizes without the source excess (i.e. S) across both Pipes. This is not a requirement, but it will be left to the reader to extrapolate the equations within this section for asymmetric S terms.

Locating the seam within an image that spans the horizontal Pipe Source Size across both Pipes (e.g. the desktop/background image) is simply a function of the Pipe. But, if a Plane image is smaller than the combined horizontal Pipe Source Sizes, then the location of the seam is dependent on the offset of the Plane within the Pipe Source Window.



So, if the addition of the Plane Position (PP) and the Full H. Plane Size (HPS) is greater than S, then the following equations define where the seam is located within the image in memory.

HPS = Left Plane Size (LPS) + Right Plane Size (RPS)

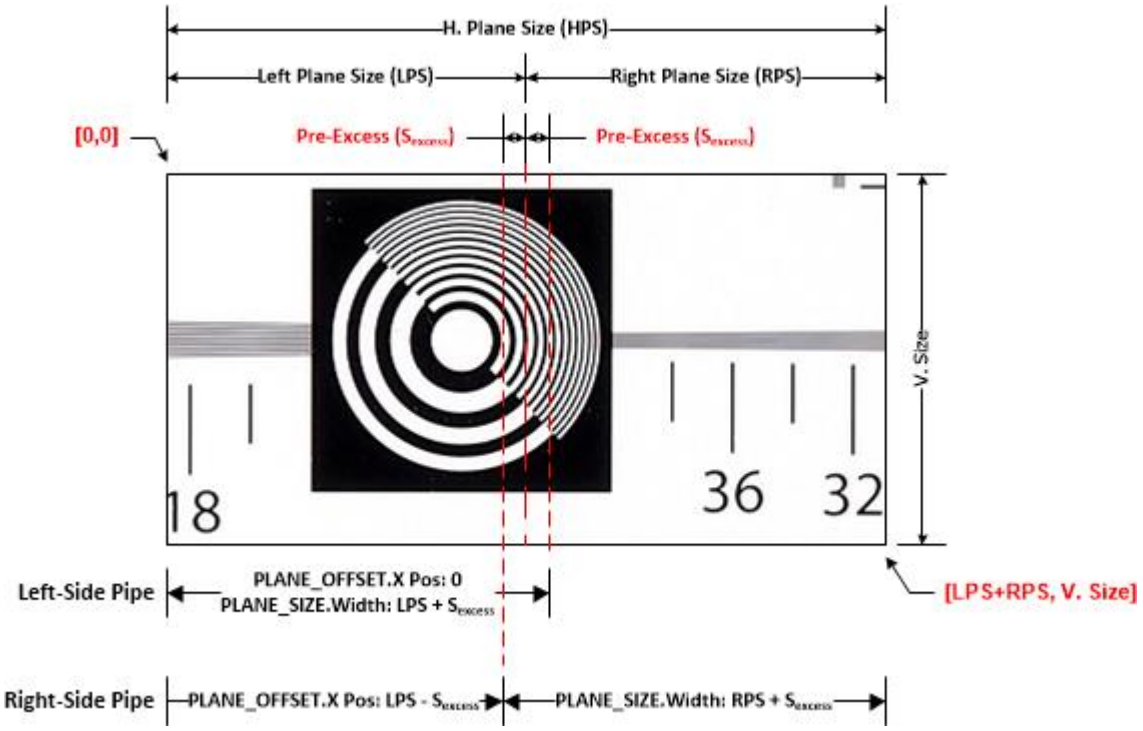
S = PP + LPS => **LPS = S - PP**

RPS = HPS - (S - PP)

Note that the Source Excess (S_{excess}) is a constant regardless of where the Plane image is located.

Splitting the Image

Now that the location of the seam is known, splitting the image across both Pipes can be performed. This is done using the PLANE_OFFSET and PLANE_SIZE registers.



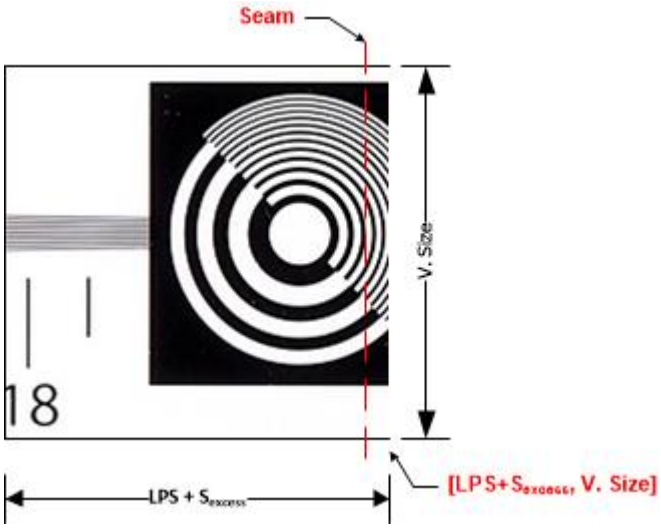
Using the figure above as a reference, to split the image in memory across the two Pipes.

Left PLANE_OFFSET:

- Starting X Position = H. Cropping Position (HCP) + 0
- Starting Y Position = V. Cropping Position (VCP) + 0

Left PLANE_SIZE:

- Width = Left Plane Size (LPS) + Pre-Excess Size (S_{excess})
- Height = V. Size

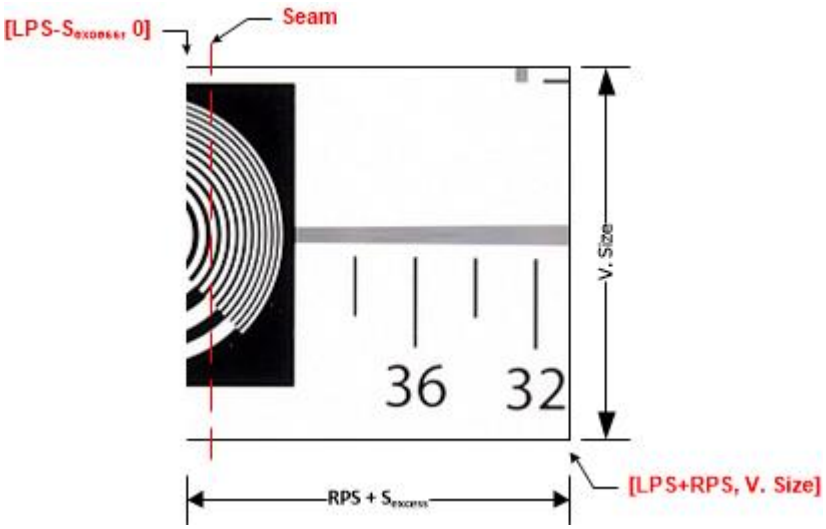


Right PLANE_OFFSET:

- Starting X Position = HCP + LPS - S_{excess}
- Starting Y Position = VCP + 0

Right PLANE_SIZE:

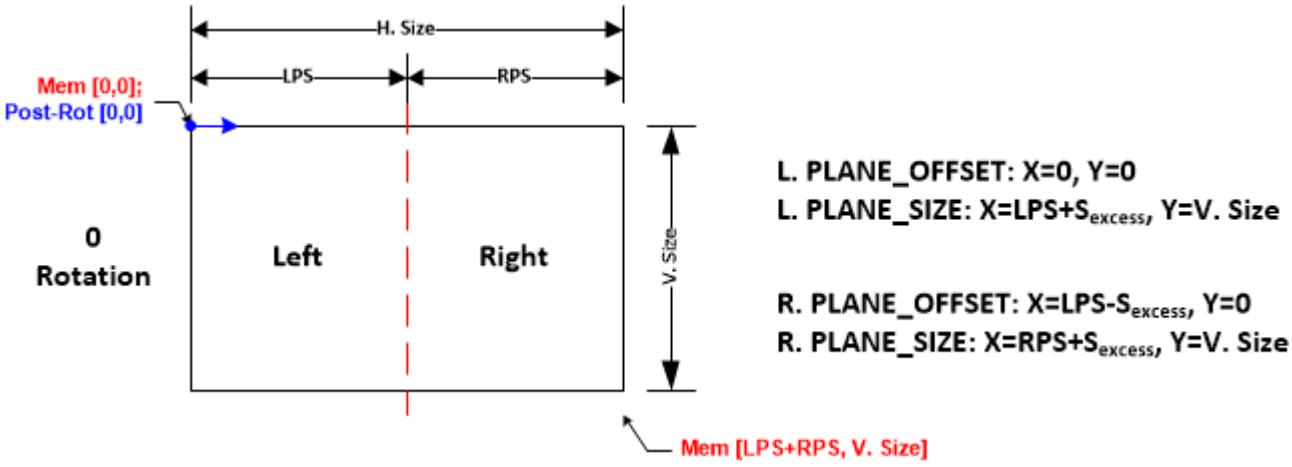
- Width = Right Plane Size (RPS) + S_{excess}
- Height = V. Size



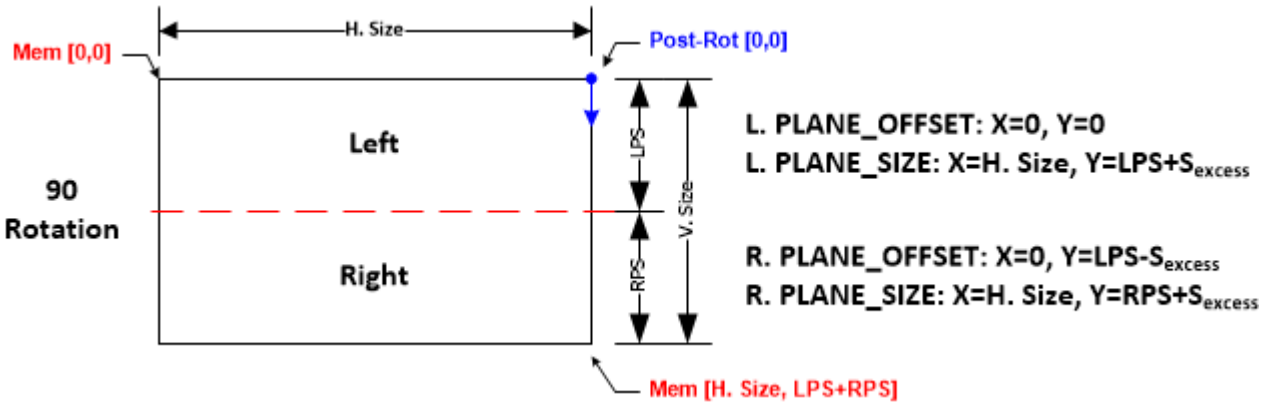
Rotation

The above discussion for splitting an image is when there is no rotation. If the image is to be rotated, then the programming of the PLANE_OFFSET and PLANE_SIZE needs to be adjusted accordingly. Since rotation is applied after the Plane Position and Size, the programming of these registers "rotates" to account for the image rotation.

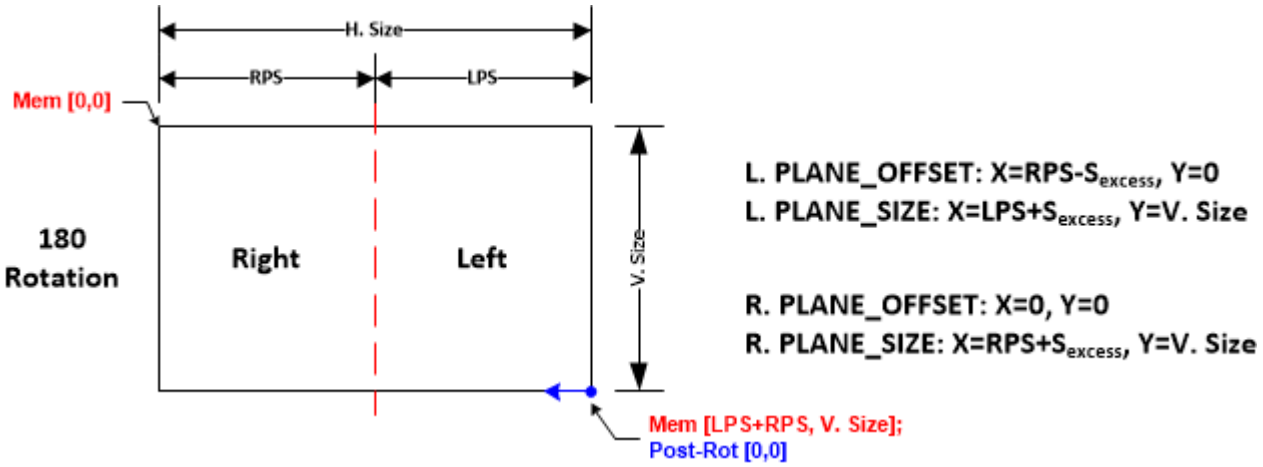
If we look at an image in memory that is going to be split without rotation, the regions of the image that are sent down each Pipe is shown below. Note that the blue dot and arrow represent the post rotation origin of the image and direction of scan.



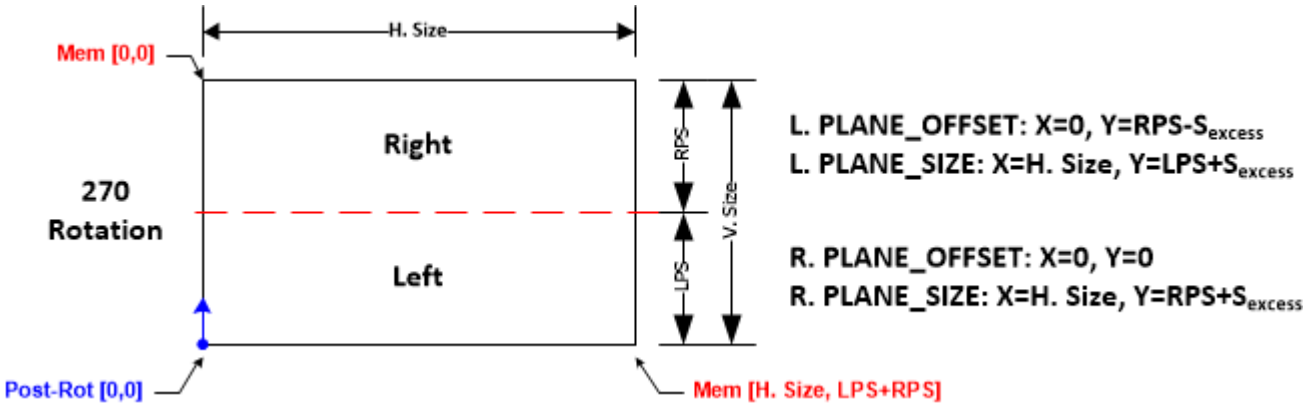
When the image is rotated by 90^o, then the horizontal and vertical sizes programmed within the Plane/Pipe are swapped. So, the left and right regions swap as well.



When rotating another 90^o (i.e. 180^o rotation), then the left and right regions swap positions with respect to the no rotation scenario.



Finally, when the image is rotated 270^o then the left and right regions swap positions with respect to the 90^o rotation scenario.

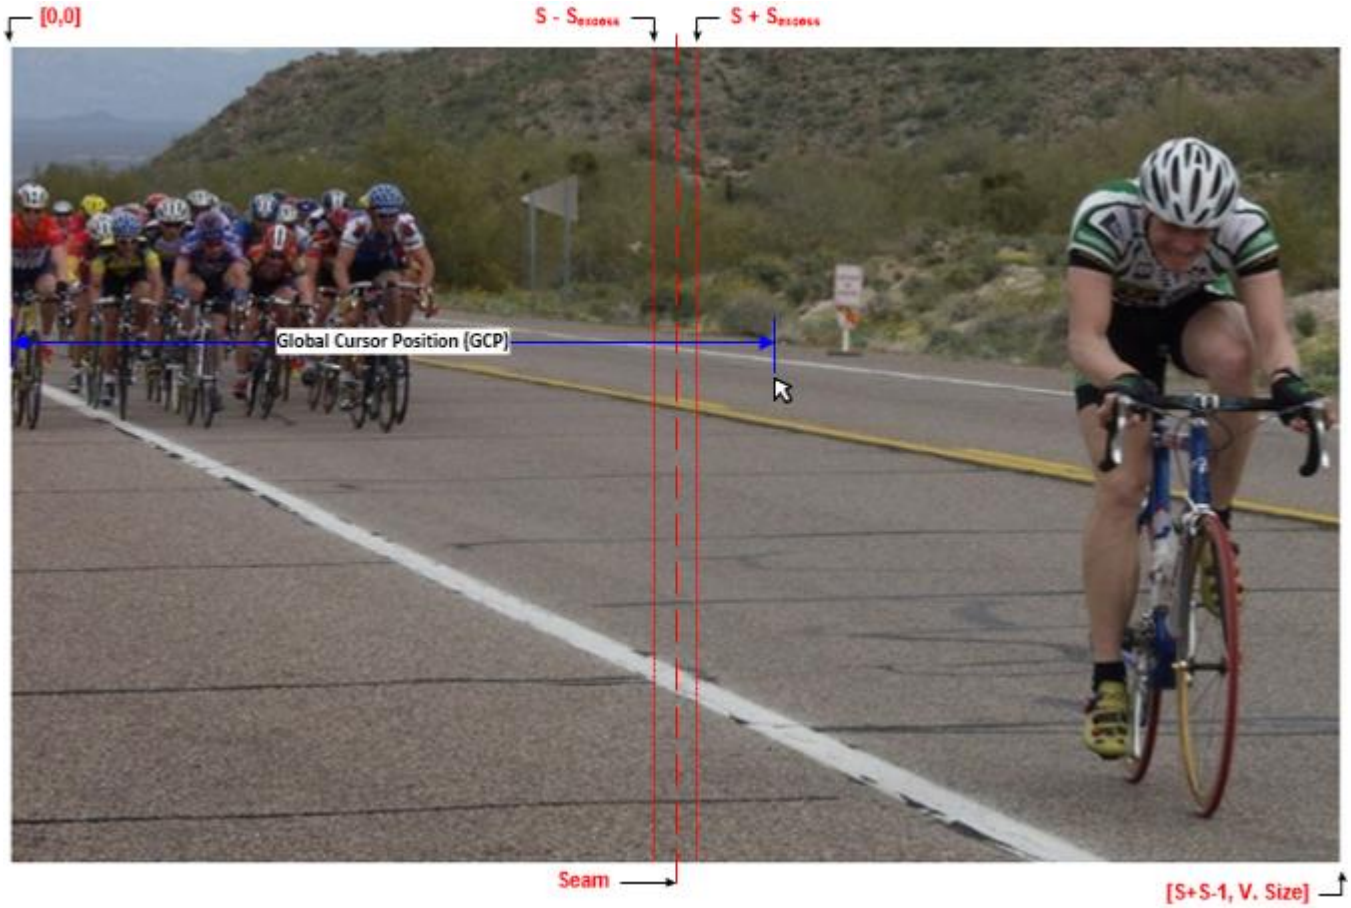


Note that Software should ensure that the horizontal Plane position for the image in the right Pipe is zero (i.e. there should be no positional offset of the image with respect to the seam)

Refer to the table within the Source Image Manipulation below for a summary of the Plane offset and size programming.

Cursor

The mechanism that Software uses to determine the horizontal position of the Cursor across both Pipes is beyond the scope of this document. However, to explain how the Cursor is enabled/programed around the seam, this document will use a global coordinate system that spans across both Pipe source windows.



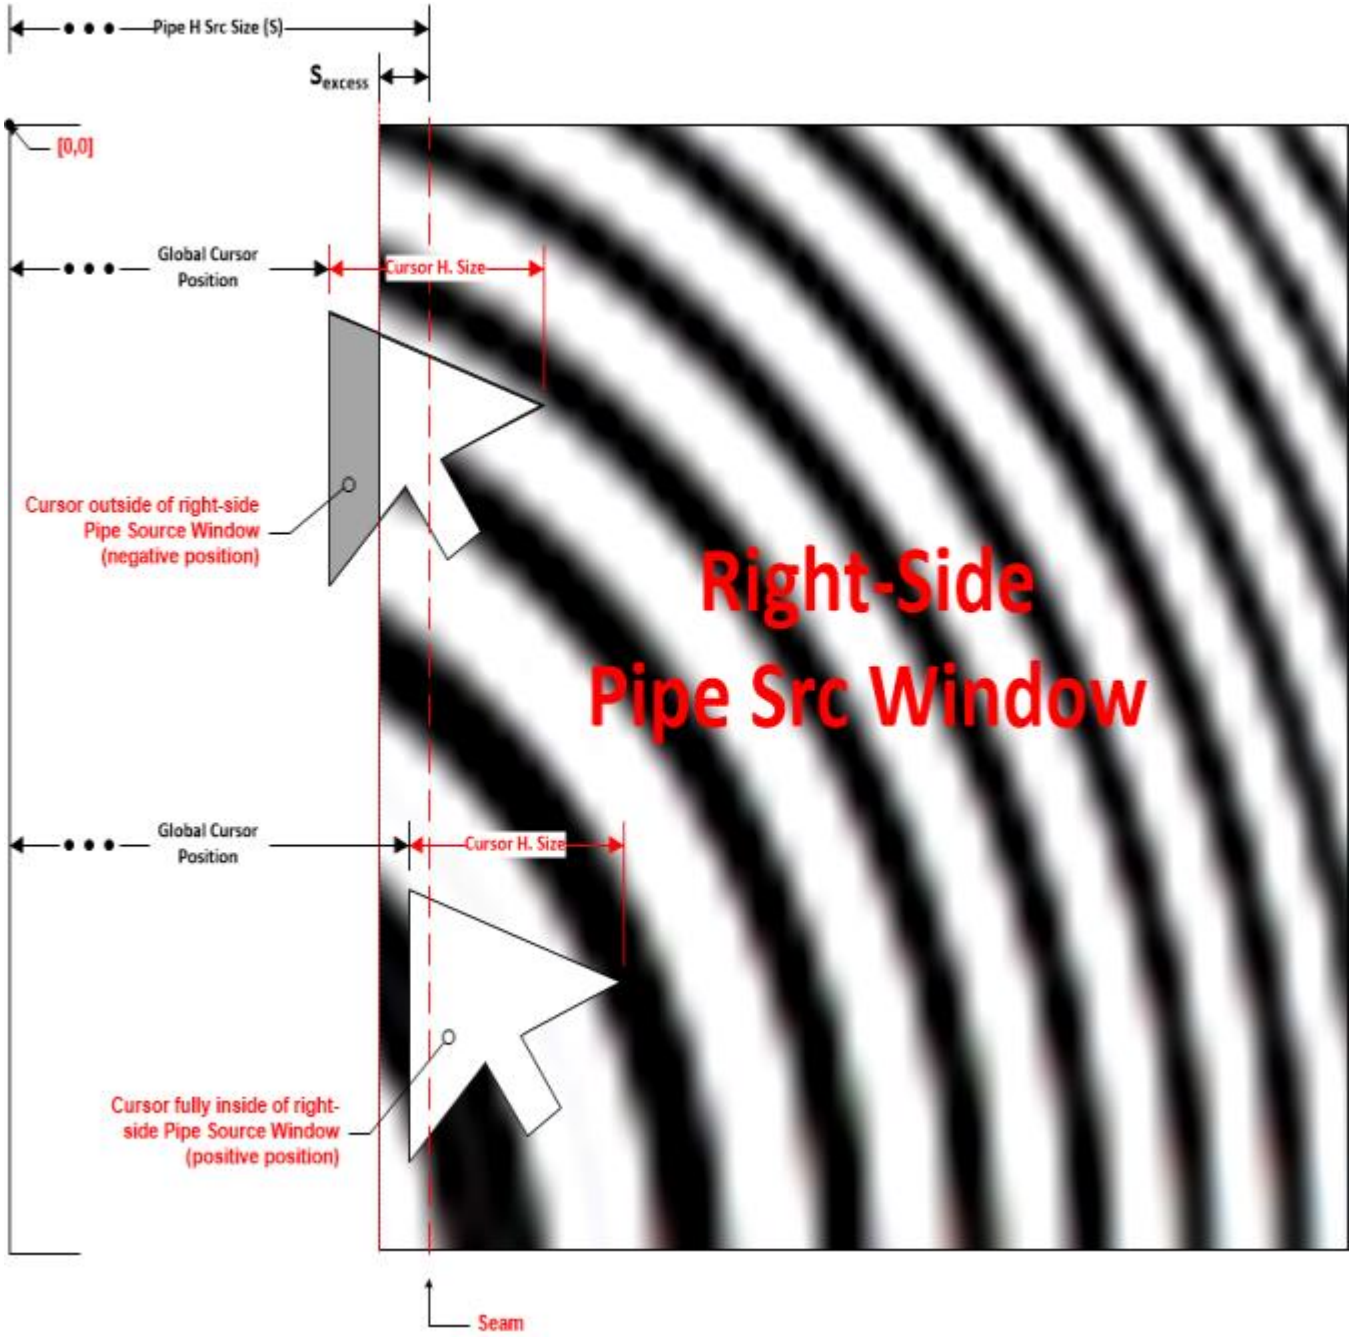
The horizontal position of the Cursor will be referred to as the global cursor position (GCP) that will span across both Pipe source windows from 0 to (2*S)-1.

When the Cursor is outside of the seam "window" (S +/- S_{excess}), then only one Pipe will have its Cursor enabled. As the Cursor moves into the seam window, then both Pipes will need to enable its Cursor. Determining when the Cursor is within this window is dependent on the global cursor position and the Cursor size (CS).

Global Cursor Position	Left Pipe Cursor	Right Pipe Cursor
GCP < (S - S_{excess} - CS)	Enabled	Disabled

(S - S_{excess} - CS) <= GCP < (S + S_{excess})	Enabled	Enabled
GCP >= (S + S_{excess})	Disabled	Enabled

The positioning of the Cursor will be dependent on where the Cursor is within the seam window. The left-side Cursor position is directly based off of the global cursor position, but the right-side Cursor is a little more involved.



The following table illustrates how to determine the Cursor position when it is crossing the seam.

Global Cursor Position	Left Pipe Cursor Position	Right Pipe Cursor Position
GCP < (S - S_{excess} - CS)	Magnitude = GCP Sign = SW determines	N/A (Disabled)
(S - S_{excess} - CS) <= GCP < (S - S_{excess})	Magnitude = GCP Sign = Positive	Magnitude = S - S_{excess} - GCP Sign = Negative
(S - S_{excess}) <= GCP < (S + S_{excess})		Magnitude = GCP - S - S_{excess} Sign = Positive
GCP >= (S + S_{excess})	N/A (Disabled)	

Calculating Pre and Post Excess Sizes

To get an accurate sampling across the seam, the number of pre-scaled excess pixels (a.k.a. Source Excess, S_{excess}) needs to (at a minimum) fill the number of FIR taps to the left or right of the horizontal FIR's Center Tap.

$$\mathbf{S_{excess} >= (NUMTAPS - 1)/2}$$

Note that the Display Pipe requires an even number of line pixels, so the source excess may need to be rounded up to the next even number.

To determine the number of post-scaled excess pixels (a.k.a. Destination Excess, D_{excess}) we can use the following equation:

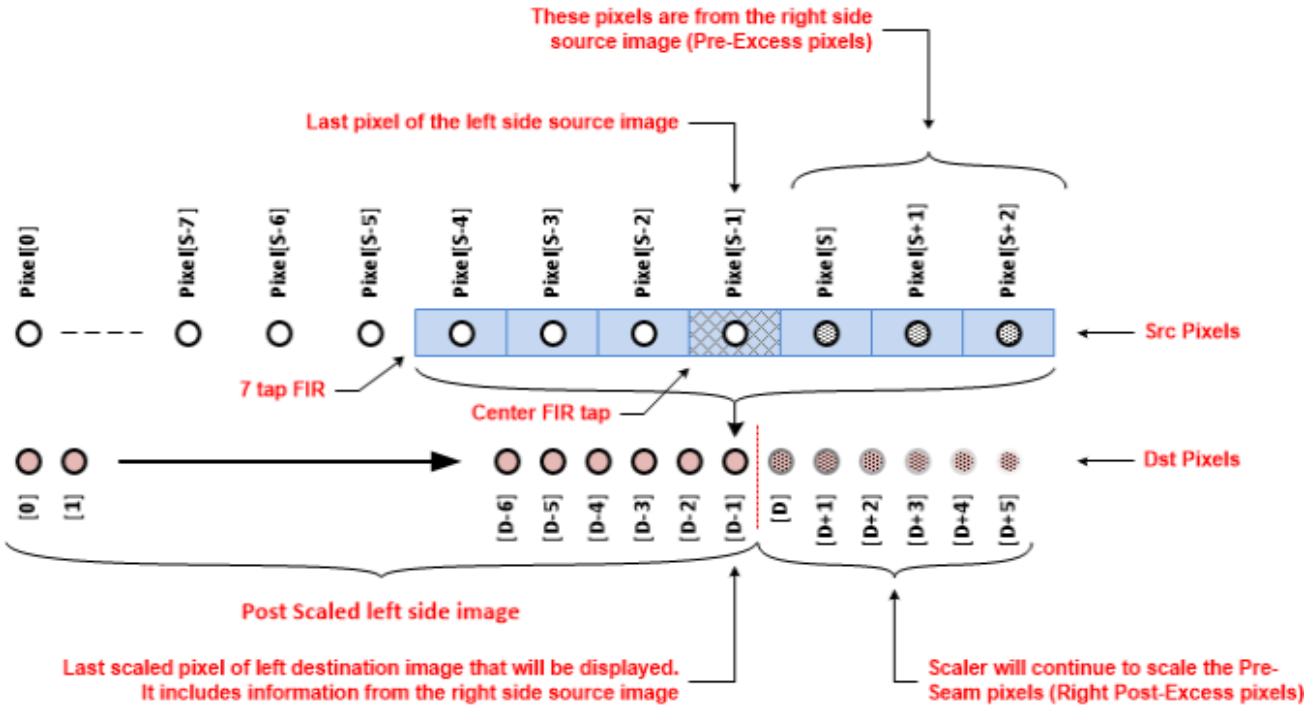
$$SF_{target} = (S + S_{excess}) / (D + D_{excess})$$

$$\mathbf{D_{excess} = Round(((S + S_{excess}) / SF_{target}) - D)}$$

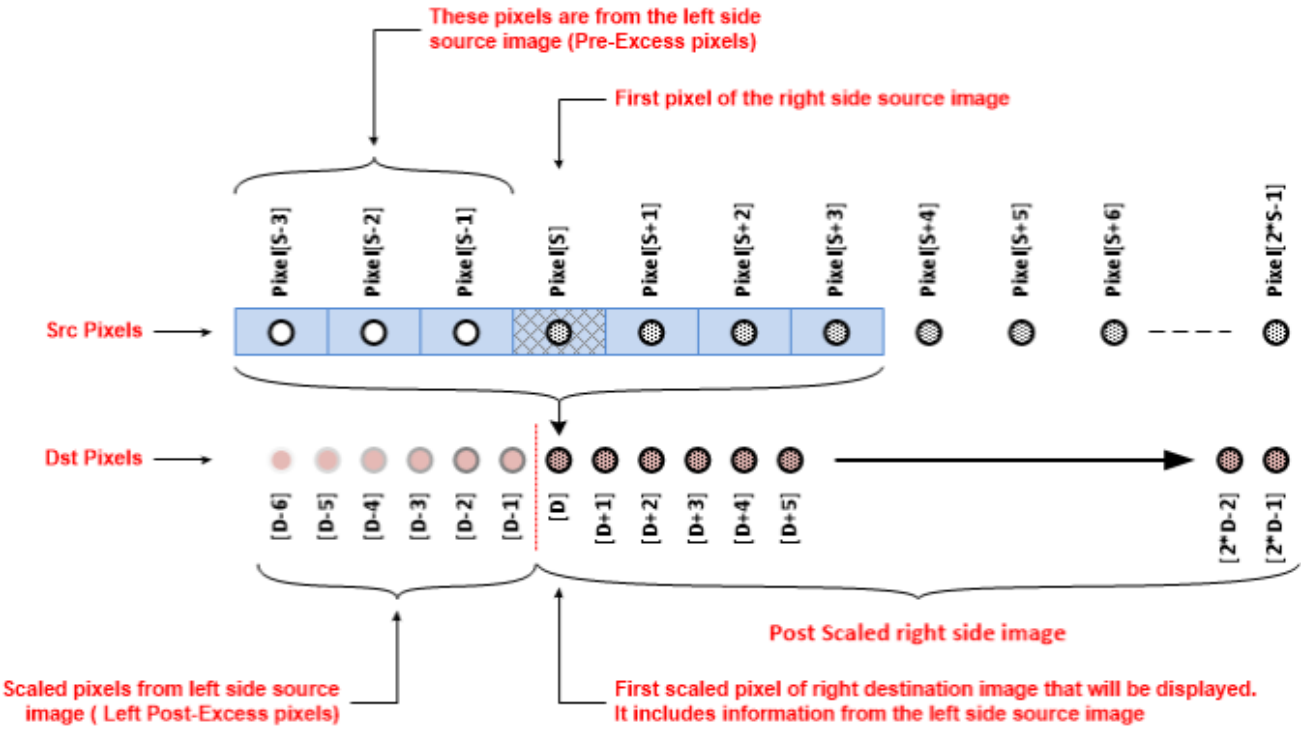
Where:

- S is the Source size in pixels per Pipe (one-based and without excess pixels)
- D is the Destination size in pixels per Pipe (one-based and without excess pixels)
- SF_{target} is the target Scale Factor (i.e. S/D)

Note that the D_{excess} must be a multiple of DISP_NUMPPC since the pixel dropping logic works at that granularity.



The above illustrates the Scaler output for the left side image (seam is on the right side). As the last pixel of the left side source image moves into the center tap of the Scaler's FIR, all of the taps to the right of the center tap contain pixels from the right side source image (Pixels S to S+2). The resulting destination pixel (this is the last displayable pixel) will contain all of the necessary information from the right side of the source image. All of the pixels beyond the last pixel of the destination image are the post excess pixels and those will be dropped.

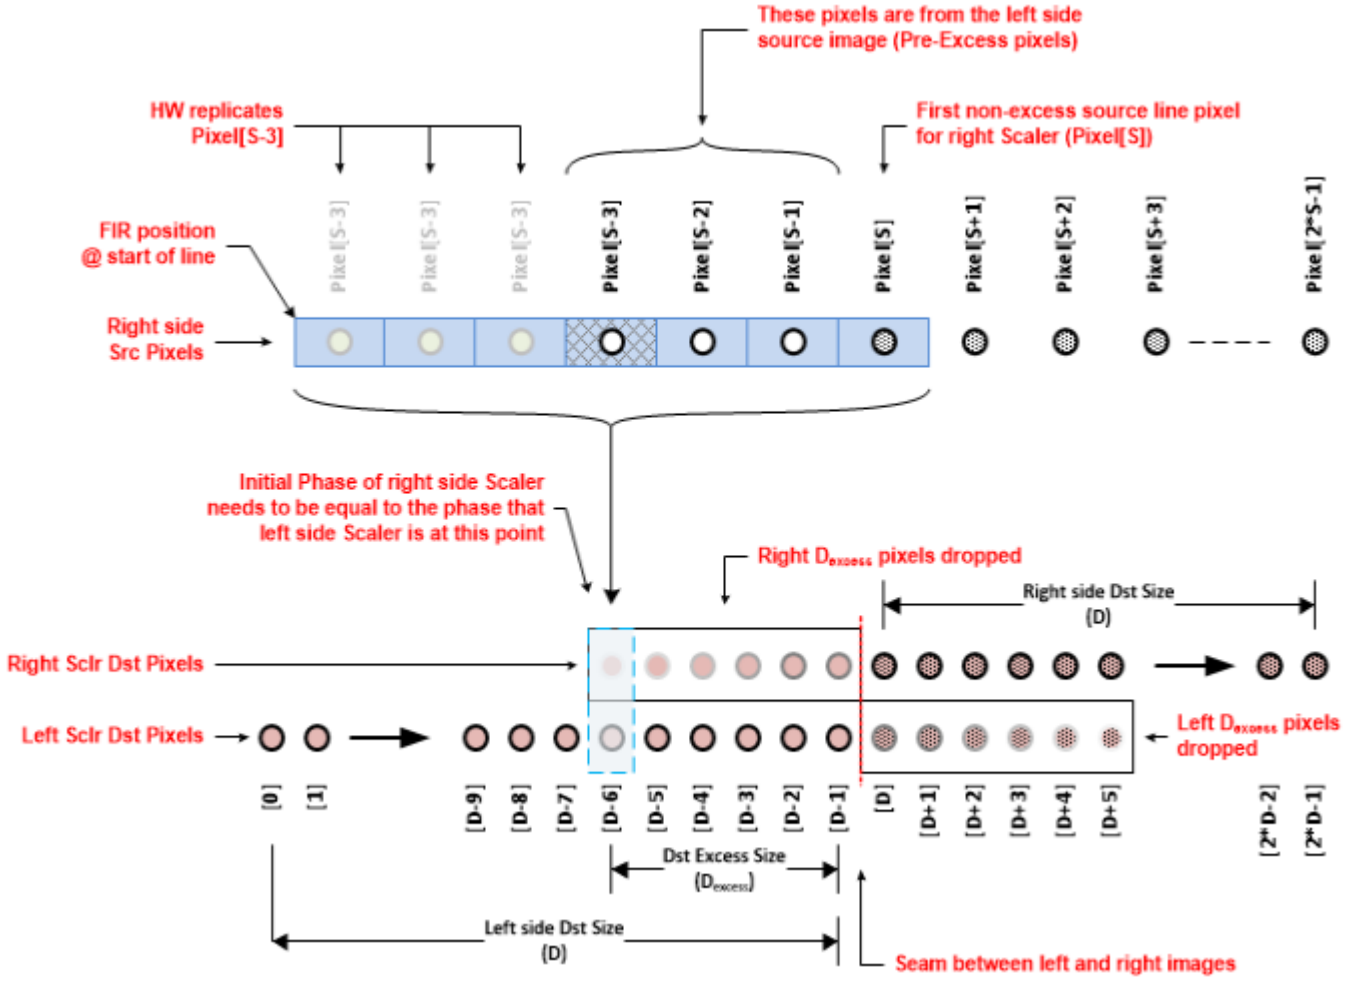


The above illustrates the Scaler output for the right side image (seam is on the left side). As the FIR progresses, the first pixel of the right side source image eventually moves into the center tap and all of the taps to the left of the center tap contain pixels from the left side source image (Pixels S-3 to S-1). All pixels up to this point are the post excess pixels that will be dropped. The resultant destination pixel when the first right side source image pixel makes it to the center pixel contains all of the necessary information from the left side of the source image.

Calculating Initial Phases

To ensure the image from both Pipes appears to be scaled by a single Scaler, the horizontal initial phase for the Scaler processing the right-side image will need to be set such that the phase of the horizontal FIR of the right Scaler picks up where the horizontal FIR of the left Scaler leaves off.

When the horizontal filter starts processing a line, it will load the first source pixel of the line into the Center Tap of the FIR and then apply an initial phase from that point (note that the Scaler can only apply positive initial phases). For the right-side Scaler, the first pixel of the source line will be the left most Source Excess pixel (i.e. a pixel from the left source image). To match the phase of the horizontal FIR of the right-side Scaler at the **beginning** of its source line with the phase of the horizontal FIR of the left-side Scaler at the **end** of its source line we need to determine the phase of the left-side Scaler's horizontal FIR (D_{excess}-1) pixels **before** it reaches the final Destination pixel (D-1).



The following equation is used to determine the phase that the right-side Scaler needs to start at.

$$\mathbf{P_{right} = SF_{actual} * (D - D_{excess})}$$

Notes:

1. To get an accurate initial phase, need to use the actual scale factor (SF_{actual}) that the Scaler on the left is using. Depending on configuration, this is not always the target scale factor
   a. If the Scaler HW is calculating the Scale Factor: SF_{actual} = (S + [Left, Right] S_{excess}) / (D + D_{excess})
   b. If the Scaler HW is using the programmed Scale Factor: SF_{actual} = PS_PROG_HSCALE
      i. The PS_PROG_HSCALE register should equal the target Scale Factor (SF_{target})
2. The Scale Factor has a precision of 2.14, regardless of how it is calculated. However, HW will automatically round the Scale Factor (Software should do the same)

The absolute phase difference between the left and the right will be used as the Horizontal Initial Phase (HIP) to be applied to either the left or right side.

$$\mathbf{Absolute\ Horizontal\ Initial\ Phase = |\ (S - S_{excess}) - P_{right}\ |}$$

The side that the initial phase is applied will depend on which side is ahead of the other.

- If the left-side Scaler phase is less than or equal to the source pixel that the right-side Scaler starts at (i.e. (S - S_{excess}) - P_{right} is positive) then the HIP will be applied to the left-side Scaler
- Otherwise, the HIP will be applied to the right-side Scaler

Notes:

1. Make sure to set the Initial Phase Trip bit of PS_HPHASE
2. The act of applying an initial phase will cause the image (on the left or the right) to appear to "shift". The shifting will be more evident for the left-side.

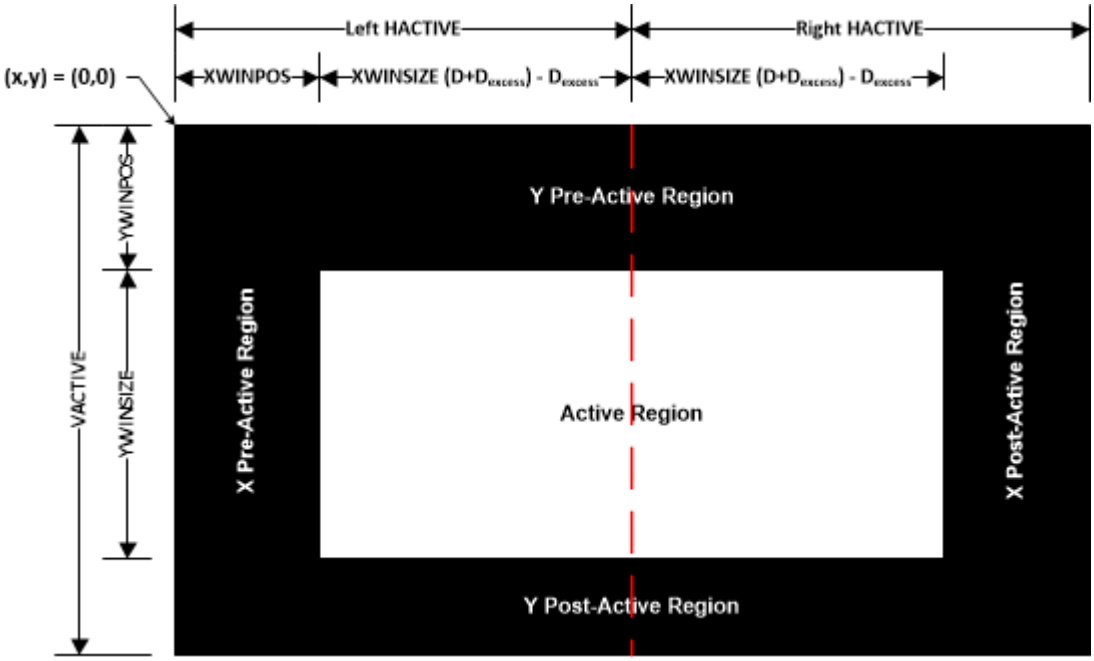
The following table illustrates an example of a 1920x1080 source image that is split across two Pipes with Pipe Source Sizes of 960 + S_{excess}.

		Notes
Source Size (S)	960	Horizontal Pipe Source Size w/o S_{excess}
Source Excess (S_{excess})	4	EVEN((NUMTAPS -1)/2)
Destination Size (D)	2576	Number of destination pixels per Pipe w/o D_{excess}
Target Scale Factor (SF_{target})	0.372670807	S/D
Actual Scale Factor (SF_{actual})	0.372497559	HW calculated by left Scaler: (S + S_{excess}) / (D + D_{excess}) Result is rounded to 2.14 precision
Destination Excess (D_{excess})	12	ROUND(((S + S_{excess}) / SF_{target}) - D)
Initial Phase needed on Right (P_{right})	955.0837402	SF_{actual} * (D - D_{excess})
First Src Pixel on Right	956	S - S_{excess}
Absolute Horizontal Initial Phase	0.9162598	| (S - S_{excess}) - P_{right} |

Left Scaler Initial Phase	0.9162598	(S - S_{excess}) >= P_{right}
Right Scaler Initial Phase	0.0	(S - S_{excess}) >= P_{right}

Pillar Box Windowing

If pillar-box borders are going to be applied by the Scaler, then Software will need to account for this across both Pipes when programming the PS_WIN_POS register.



As we can see from the above illustration, the left-side border is applied by the PS_WIN_POS programming of the left-side Scaler and the right-side border is applied by the H. Active programming of the right-side transcoder.

Left Side:

- PS_WIN_POS.X Position = Left side border size
- TRANS_HTOTAL.H Active = Destination image size w/o excess (D) + Left border size

Right Side:

- PS_WIN_POS.X Position = 0
- TRANS_HTOTAL.H Active = Destination image size w/o excess (D) + Right border size

Summary:

The following is a summary of the above discussion that Software will need to perform for tiled Pipe scaling.

Some general notes:

1. Adding excess pixels for tiled Pipe scaling is only necessary when upscaling the tiled images. If downscaling the tiled images, then excess pixels do not need to be added.
2. This document assumes that the pre-excess horizontal Pipe Source Size (i.e. S) is symmetric across both Pipes (i.e. S is the same for both the left and right-side Pipes). It is not a requirement that this term be symmetric, but it will be left to the reader to extrapolate the equations within this document for asymmetric S terms.

Source Image Manipulation

- **S is the horizontal Pipe Source Size without S_{excess} pixels (one-based)**
- **S_{excess} >= (NUMTAPS - 1)/2**
    - **NUMTAPS = 7**
    - **Round up the result to the nearest NUMPPC (NUMPPC=2)**
- **If the sum of the Plane Position (PP) and the Full H. Plane Size (HPS) is greater than S (i.e. (PP + HPS) > S):**
    - **HPS = Left Plane Size (LPS) + Right Plane Size (RPS)**
    - **LPS = S - PP**
    - **RPS = HPS - (S - PP)**

Note that the "Full H. Plane Size" is the size of the Plane image after rotation.

The following table summarizes how the Plane offset, position, and size programming changes with rotation. Some notes:

1. The programming reflected in this table is only applicable for Plane images that straddle the seam (i.e. (PO + HPS) > S)
2. The Plane offset programming in the table is not accounting for any image cropping that software may be applying to the image in memory
3. Software should ensure that the horizontal Plane position for the image in the right Pipe is zero (i.e. there should be no positional offset of the image with respect to the seam)
4. As the diagrams above illustrate, depending on rotation the LPS and RPS terms are either based off the horizontal or vertical size of the image in memory. The terms will be denoted with "h" or "v" subscripts to differentiate which size the term is based off.

Rotation	Side	Register	Field	Programming
0	Left	PLANE_OFFSET	Starting X Pos	0
			Starting Y Pos	0
		PLANE_SIZE	Width	$LPS_h + S_{excess}$
			Height	V. Size

	Right	PLANE_OFFSET	Starting X Pos	LPS_h - S_{excess}
			Starting Y Pos	0
		PLANE_SIZE	Width	RPS_h + S_{excess}
			Height	V. Size
90	Left	PLANE_OFFSET	Starting X Pos	0
			Starting Y Pos	0
		PLANE_SIZE	Width	H. Size
			Height	LPS_v + S_{excess}
	Right	PLANE_OFFSET	Starting X Pos	0
			Starting Y Pos	LPS_v - S_{excess}
		PLANE_SIZE	Width	H. Size
			Height	RPS_v + S_{excess}
180	Left	PLANE_OFFSET	Starting X Pos	RPS_h - S_{excess}
			Starting Y Pos	0
		PLANE_SIZE	Width	LPS_h + S_{excess}
			Height	V. Size
	Right	PLANE_OFFSET	Starting X Pos	0
			Starting Y Pos	0
		PLANE_SIZE	Width	RPS_h + S_{excess}
			Height	V. Size
270	Left	PLANE_OFFSET	Starting X Pos	0
			Starting Y Pos	RPS_v - S_{excess}
		PLANE_SIZE	Width	H. Size
			Height	LPS_v + S_{excess}

	Right	PLANE_OFFSET	Starting X Pos	0
			Starting Y Pos	0
		PLANE_SIZE	Width	H. Size
			Height	RPS_v + S_{excess}

Cursor

Global Cursor Position	Left Pipe Cursor	Right Pipe Cursor
GCP < (S - S_{excess} - CS)	Enabled	Disabled
(S - S_{excess} - CS) <= GCP < (S + S_{excess})	Enabled	Enabled
GCP >= (S + S_{excess})	Disabled	Enabled

Global Cursor Position	Left Pipe Cursor Position	Right Pipe Cursor Position
GCP < (S - S_{excess} - CS)	Magnitude = GCP Sign = SW determines	N/A (Disabled)
(S - S_{excess} - CS) <= GCP < (S - S_{excess})	Magnitude = GCP Sign = Positive	Magnitude = S - S_{excess} - GCP Sign = Negative
(S - S_{excess}) <= GCP < (S + S_{excess})		Magnitude = GCP - S - S_{excess} Sign = Positive
GCP >= (S + S_{excess})	N/A (Disabled)	

Post-Excess

- **D is the number of non-excess destination pixels per Pipe (one-based)**
- **SF_{target} = S/D**
- **SF_{actual}**
    - **Scaler calculates Scale Factor: (S + [Left, Right] S_{excess}) / (D + D_{excess})**
    - **Programmed Scale Factor: SF_{target} (PS_PROG_HSCALE)**
    - Hardware maintains the Scale Factor at a precision of **2.14. When the Scaler calculates the Scale Factor, it will round the result.**
- **D_{excess} = ROUND(((S + Left S_{excess}) / SF_{target}) - D)**
    - **Round up to the nearest NUMPPC**

Initial Phase

- **P_{right} = SF_{actual} * (D - D_{excess})**
- **Absolute H. Initial Phase = | (S - S_{excess}) - P_{right} |**
    - **Absolute HIP applied to left-side Scaler if (S - S_{excess}) >= P_{right}**
    - **Absolute HIP applied to right-side Scaler if (S - S_{excess}) < P_{right}**

Impacts of Plane Scaling

If a Plane is being scaled across a seam, then the following variables will be impacted:

- The S_{excess} in the PLANE_SIZE will be unchanged
- The S_{excess} in the Pipe Source size will be equal to the D_{excess} from the Plane Scaler
- The D_{excess} at the outlet of the Pipe will be calculated based off the S_{excess} in the Pipe Source
- The Pipe Scaler's actual scale factor will be based off the S_{excess} in the Pipe Source and the D_{excess} at the outlet of the Pipe

Affected Registers

The following table summarizes the registers directly affected when multi-Pipe Scaling is being employed

Register	Field	Programming
PLANE_POS	X/Y Position	See above "Source_Image_Manipulation" section
PLANE_OFFSET	Start X/Y Position	See table above in "Source_Image_Manipulation"
PLANE_SIZE	Width/Height	See table above in "Source_Image_Manipulation"
PIPE_SRCSIZE	H. Source Size	S + S_{excess}
PIPE_SEAM_EXCESS		**Left Side:** Right Excess Amount = D_{excess} **Right Side:** Left Excess Amount = D_{excess}
PS_WIN_SZ	X Size	D + D_{excess}
PS_HPHASE	RGB Initial H. Phase (Integer & Fraction)	Programming dependent on comparison of (S - S_{excess}) and P_{right} Note that the Initial H. Phase Trip bit should be set
PS_WIN_POS	X Position	**Left Side:** Left side border size, **if a border is present** **Right Side:** This should always be zero
TRANS_HTOTAL	H. Active	**Left Side:** D + Left side border size (if border present) **Right Side:** D + Right side border size (if border present)

Planes

Flips

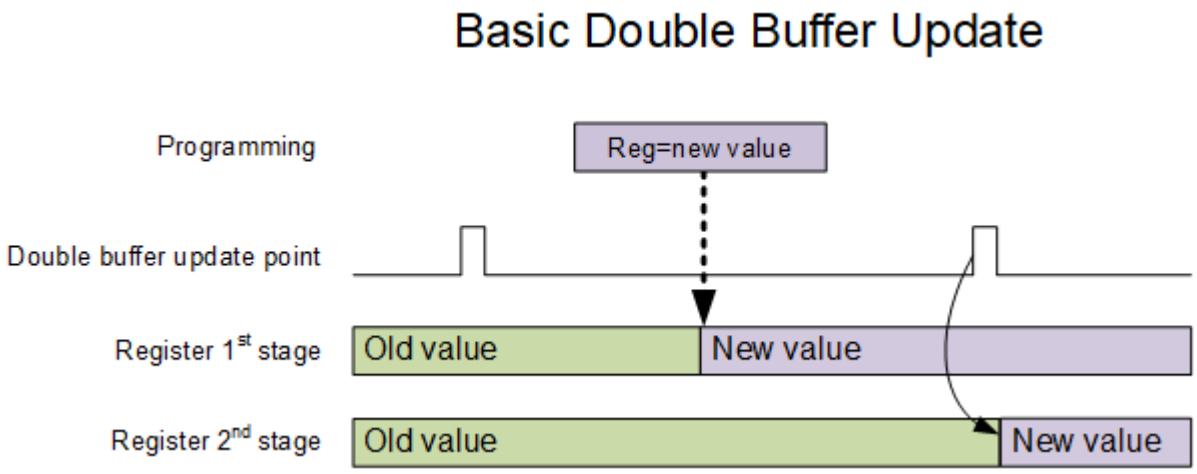
Overview

Display flips originally referred to switching between frame buffer surfaces to change the image. The term has evolved to refer more generally to an update to a plane configuration. Cursor configuration changes can also be considered to have flips, although it's more rare to describe a cursor update that way. Even updates to an enabled display pipe, such as new color correction settings, can be considered a flip, but usually only when combined with changes to the planes. A flip can be as small as updating one plane's surface address to a new frame buffer location, or as large as a synchronized update to planes, cursors, color correction, scaling, and transcoder metadata, across multiple running pipes.

Double Buffering

Most configuration that is allowed to be changed while a function is enabled, such as flips, is done through double buffered registers. Double buffer registers have two stages of registers to align the configuration update to a safe point, typically the start of vertical blank.

Writes and reads to double buffer registers access the first stage. The first stage is transferred to the second stage at the double buffer update point. The second stage is the "live value" that goes to the function being configured.



Some functions, such as planes, have read only registers to read the "live value" from the second stage.

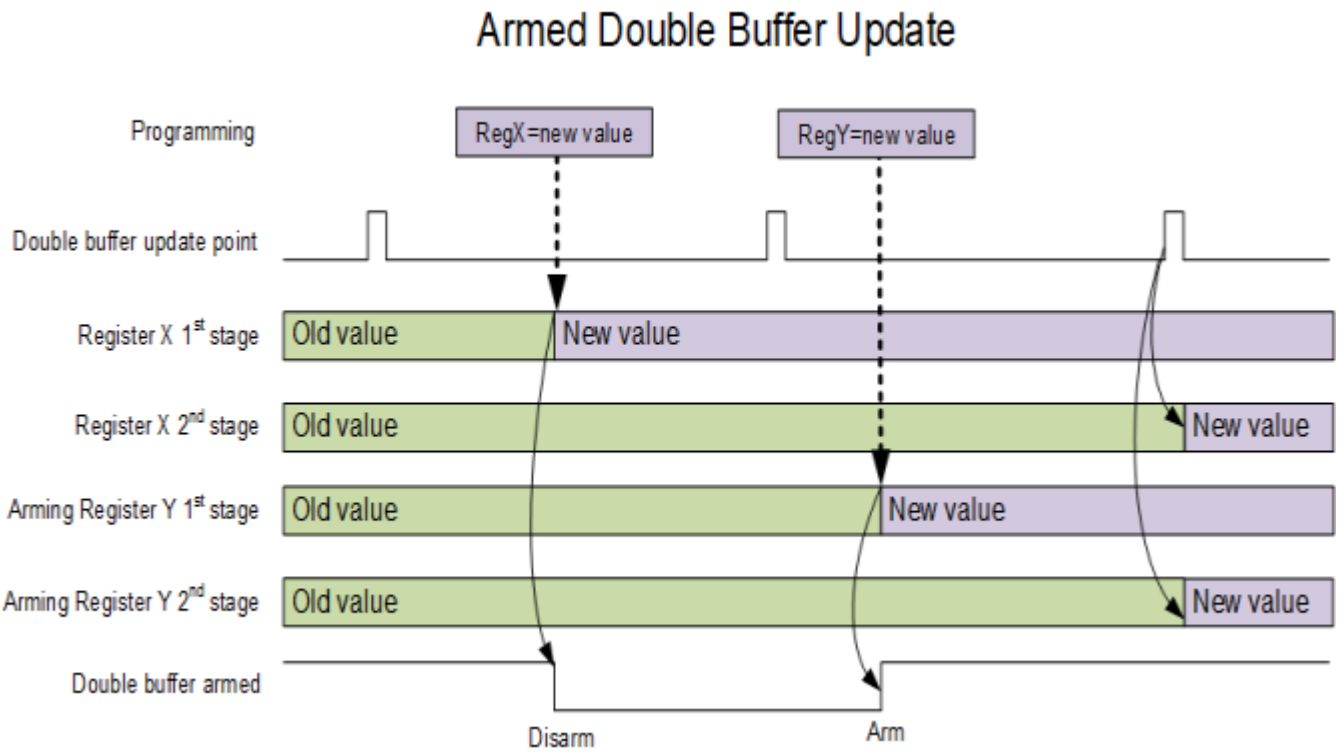
Arming and double buffer stalling are used for some registers to control the double buffer update point for atomic updates across multiple registers and functions.

Atomic Updates

Updates to multiple registers of a single function can be done atomically using the arming mechanism that some functions, such as planes, use. One of the registers for the function is defined as the arming register, described in the double buffer fields of the registers. Writes to the arming register 1st stage will

arm the double buffer to update at the next double buffer update point. Writes to the other double buffered registers for that function will disarm and prevent updates at the double buffer point. The programming sequence is to write the disarming registers first and the arming register last, then all the registers update at the next double buffer update point.

Updates across multiple planes and other resources require double buffer stalling as explained in the Double Buffer Control section.



Note: Once armed, by writing to the armed by register, the registers controlled by this arming should not be changed until the double buffer update point is reached. If changed, this will disarm the sequence and will require another write to the armed by register to get it to the armed status again.

Flip Types

There are two broad types of flip; sync and async.

Synchronous Flips

Synchronous flips (sync flips) update the plane surface base address, and other double-buffered registers, at the frame boundary (start of next vertical blank). These can be used for updates across multiple functions, not just planes.

Asynchronous Flips

Asynchronous flips (async flips) update the plane surface base address as soon as possible (next TLB boundary reached or start of next vertical blank). This can cause the image to change mid-frame with a tear, but gives better responsiveness than sync flips.

Cursors cannot do async flips.

Asynchronous flip can update only the plane surface (PLANE_SURF).

Asynchronous flip completion time depends greatly on how much data has been prefetched for power savings, and can take up to 1 full frame to complete. For faster flip completion, disable FBC and render/unified compression and allocate a minimum amount of data buffer for the plane.

Flip Programming

There are two paths to programming a flip; MMIO and command ring.

MMIO Flips

MMIO writes may be used to flip.

General MMIO Sequence for Plane or Cursor Flips

1. If interrupt will be used to wait for the flip to complete, unmask and enable the flip done interrupt for the plane that will be flipped. See the Display Interrupts section. For cursors, use the vblank interrupt.
2. Write registers to update plane configuration fields besides the arming register, including PLANE_CTL Async Address Update Enable to select sync or async flip.
3. Arm the update: For planes, write PLANE_SURF with the plane surface address. For cursors, write CUR_BASE. For other resources, write the arming register as specified in registers for that resource. Some resources do not have arming.
4. Optional: Wait for the interrupt for the flipped plane. Not required if software uses other methods to find when the old surface is no longer being used.

Double buffering control does not apply to PLANE_SURF updates that occur when the plane is disabled so an interrupt event is generated immediately when the PLANE_SURF is written.

Command Ring Flips

The render command MI_DISPLAY_FLIP may be used to flip. Typically it is only used for plane surface address updates, but it can be extended to more complicated flips.

MI_DISPLAY_FLIP can be combined with LOAD_REGISTER_IMMEDIATE, which behaves like a MMIO write, to update other parts of a plane configuration.

General Command Sequence for Plane Flips

1. If MI_WAIT_FOR_EVENT will be used to wait for the flip to complete, unmask flip done for the plane that will be flipped in DE_RRMR using MMIO or LOAD_REGISTER_IMMEDIATE. See the Render Response section.
2. Optional: LOAD_REGISTER_IMMEDIATE to write registers to update plane configuration fields that are not included in the MI_DISPLAY_FLIP_COMMAND.
3. MI_DISPLAY_FLIP to update plane surface address and other configuration listed in the command details (stride, tile format, and more), and select sync or async flip. The flip is self arming.
4. Optional: MI_WAIT_FOR_EVENT to wait for the flip to complete for the flipped plane. Not required if software uses other methods to find when the old surface is no longer being used.
5. Re-mask the flip done in DE_RRMR using MMIO or LOAD_REGISTER_IMMEDIATE. It does not need to be immediately re-masked, but unmasked events will wake GT as they occur, so for improved power savings it is recommended to only unmask events as they are required.

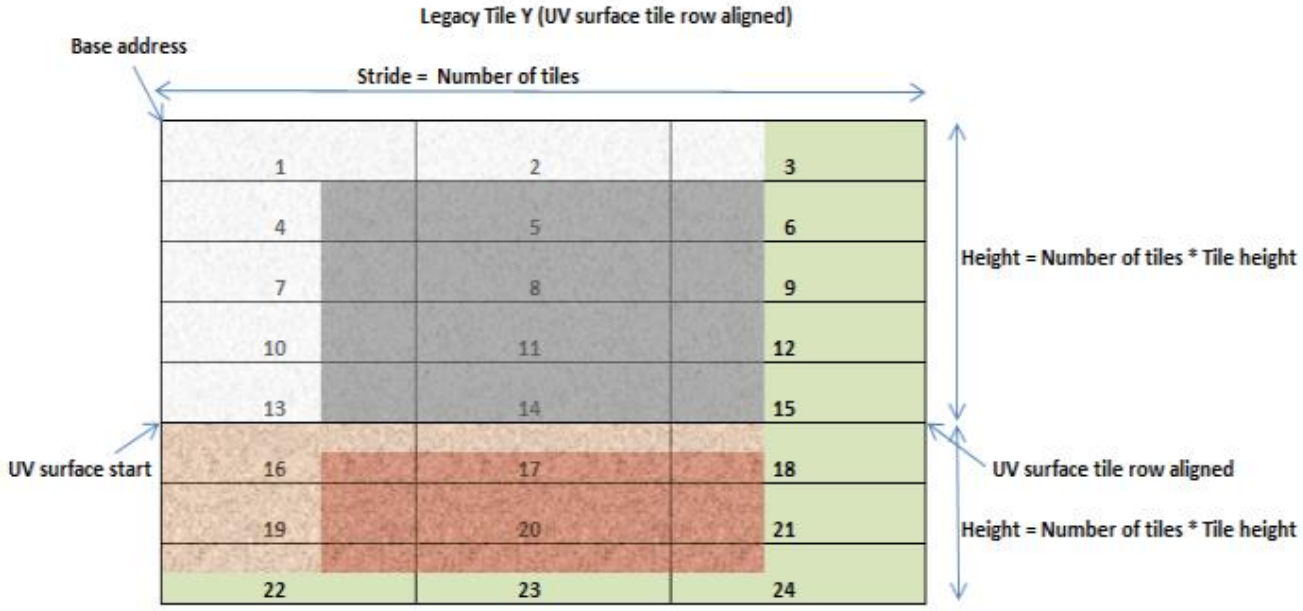
Flips to a plane that is disabled or on a disabled pipe will complete immediately and send the flip done.

Plane Planar YUV programming

YUV 420 hybrid planar formats (NV12, P0xx) have Y and UV surfaces stored separately. Display supports YUV 420 planar frame buffers in linear and tiled surface formats. Each display pipe can support up to two hybrid planar YUV 420 frame buffers. Display hardware uses two planes to handle each of these framebuffers - one for Y surface data and the other for UV surface. In addition to the two planes, a plane scaler must be enabled for YUV420 to YUV444 upsampling. See the Plane Capability and Interoperability section for UV and Y surface plane assignments.

Y and UV surface Base Address, Stride and Surface Offset (Start X and Y position) must be programmed separately for Y and UV planes. Software must make sure that the Y and UV plane programming gets applied together in the same frame. The Y and UV plane programming can be synchronized using the double buffer synchronization mechanism defined in DOUBLE_BUFFER_CTL. In the case of DisplayPort VRR mode (Variable Refresh Rate), the VRR push must be used for the Y and UV plane synchronization. Software must make sure that there is no push between the Y and UV plane flips.

With tiled surfaces, the UV surface must start on a new tile row.



Y Surface

Base Address, Stride and Surface Offset (Start X and Y position) should follow the standard plane programming.

UV Surface

The UV surface has some additional requirements.

Base Address:

For UV surfaces, the programmed Base Address should satisfy the following alignment requirements:

Linear:

The UV surface Base Address programmed in the PLANE_SURF register should be aligned to Stride in bytes of the Y surface * 64.

Tiled surfaces:

The start of the UV surface programmed in the PLANE_SURF register should be Tile Row Aligned.

Surface Offset:

The UV surface offset is programmed in the PLANE_OFFSET register. In the 0/180 rotate cases, the programmed X and Y start position should be half of the Y surface start X and Y positions.

For 0/180 rotate cases:

UV surface Start X Position = half of Y plane X start position

UV surface Start Y Position = half of Y plane Y start position

For 90/270 rotate cases:

UV surface Start X Position = (UV surface height in tiles * tile height) - UV plane Y start position (non-rotated) - UV plane height (non-rotated)

UV surface Start Y Position = UV plane Start X Position (non-rotated)

90/270 Rotation

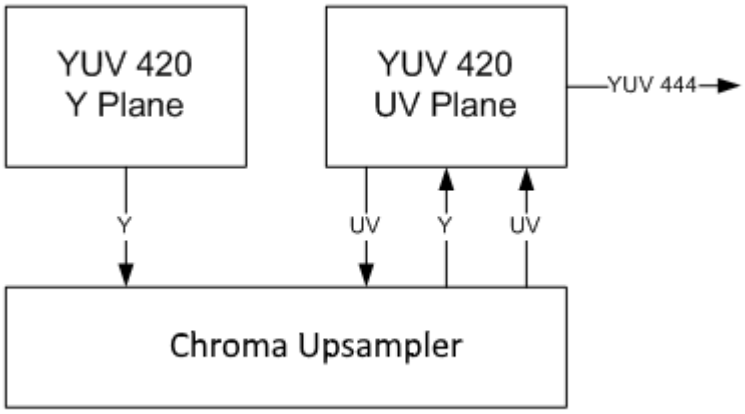
Plane 90/270 rotation support requires GTT remapping. GTT remapping allows the hardware to walk the pages sequentially. The Y and UV surfaces should be remapped separately, and the pages that contain portions of both Y and UV data will get GTT remapped twice, once for Y surface and the other for UV surface.

Upsampling and further processing

Planes 1-3 have dedicated chroma upsampler that is programmed in PLANE_CUS_CTL register.

The Y and UV plane pixels go through the chroma upsampler, gets upsampled, scaled and merged to form the YUV444 pixels for further processing.

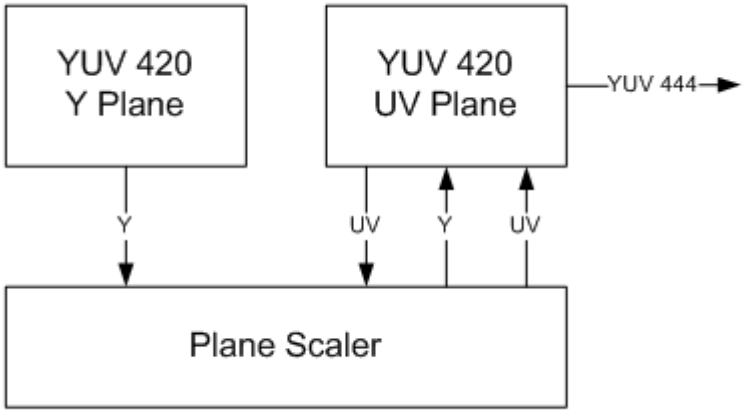
The Y plane binding is specified in the 'PLANE_CUS_CTL->Y Binding' field.



Planes 4-5 use the plane scaler for chroma upsampling.

The Y and UV plane pixels go through the plane scaler, gets upsampled, scaled and merged to form the YUV444 pixels for further processing.

The Y plane binding is specified in the 'PS_CTRL->Scaler Binding Y' field.



Destination keying, Color correction and Gamma must be programmed in the UV plane. Destination keying, Color correction and Gamma programming in the Y plane gets ignored. The UV plane position is used for blending order determination.

Flips

Since two different planes are involved in handling the pixels from a single planar YUV 420 frame buffer, we have to ensure that both the Y and UV planes' flip gets applied at the same time.

Global double buffer update disable mechanism can be used to synchronize and commit the flips atomically.

Follow the following sequence for CS, BCS or GUC flips

1. Use LRIs to set the 'Allow Double Buffer Update Disable' field for Y and UV planes.
2. Use LRI to set the 'Global Double Buffer Update Disable' field.
3. Use LRIs to update the 'Surface Base Address' and 'Stride' of the Y surface as required.
4. Send the flip messages for the UV surface.
5. Use LRI to clear the 'Global Double Buffer Update Disable' field.
6. Use LRIs to clear the 'Allow Double Buffer Update Disable' field for the Y and UV planes.

The flips will get applied in the following frame.

Follow the following sequence for MMIO flips

1. MMIOs to set the 'Allow Double Buffer Update Disable' field for Y and UV planes.
2. MMIO to set the 'Global Double Buffer Update Disable' field.
3. MMIOs to update the 'Surface Base Address' and 'Stride' of the Y surface as required.
4. MMIOs to update the 'Surface Base Address' and 'Stride' of the UV surface as required.
5. MMIO to clear the 'Global Double Buffer Update Disable' field.
6. MMIOs to clear the 'Allow Double Buffer Update Disable' field for the Y and UV planes.

The flips will get applied in the following frame.

Watermarks

Watermarks should be calculated and programmed for Y and UV planes separately. Refer to Watermarks page for further details.

Plane Capability and Interoperability

Plane Assignments and Capabilities

Plane capabilities:

- There are 7 planes + 1 cursor/pipe.
- Each planar YUV 420 surface uses 2 planes - Y and UV surfaces are handled by seperate planes which gets combined later in the pipeline. Each pipe can support up to 2 YUV 420 planar surfaces.
- HDR mode supports up to 3 planes per pipe.

Render Decompression

GT Render engines uses a lossless scheme to compress the color Render targets. The goal of the compression is to reduce the memory bandwidth. The memory foot print increases slightly due to the need of the control surface.

- Decompression is supported with RGB8888, RGB1010102 and FP16 formats.

- Decompression is supported only with legacy tile Y or tile 4 surfaces.
- Decompression support is limited to left-right cache line pair mode. Top-bottom mode is not supported.
- Decompression is not supported with 90/270 degree rotation.
- Compressed displayable surfaces must be 16KB aligned and have pitches padded to multiple of 4 tiles.

Color Control Surface

The Color Control Surface (CCS) contains the compression status of the cache-line pairs**.** CCS stride is programmed separately independent of the main surface stride. The compression state of the cache-line pair is specified by 4 bits in the CCS. The address of CCS surface is specified as an offset from the start of the Render Target main surface.

Decompression Programming

When compressed Render targets are presented to Display, the display decompression must be enabled. Along with main surface programming, the following additional programming is required to enable the decompression

- **Decompression Enable**

  Decompression is enabled by programming the 'Render Decomp' bit in the PLANE_CTL register.

- **Color Control Surface Distance**

  The start of the CCS surface is programmed as the distance from the start of the main surface in the PLANE_AUX_DIST register. The CCS is always placed after the main surface and is 4K page aligned.

- **Clear color value**

  When clear color is enabled in PLANE_CTL register, the clear color value must be programmed in the PLANE_CC_VAL register.

Media Decompression

The goal of the compression is to reduce the memory bandwidth. The memory foot print increases slightly due to the use of the control surface.

Display supports decompression of compressed media surfaces. 4 horizontally adjacent cache lines form a compression unit and its compression status is stored in the control surface (Tile Status Surface). The address of the control surface is specified as an offset from the start of the main surface. The control surface is always linear.

With Y tiling and planar YUV surfaces UV surface, the UV surface starts right after the Y surface and it can be in the middle on the tile row. The only guarantee is that the Y surface start will be 4 lines (cache line) aligned. Y and UV surfaces have their own individual control surface and they both have to be

programmed independently. In cases where the UV plane start is not aligned to the tile row start, the UV main surface start is programmed to the previous tile row aligned address with a plane offset to the start of the UV. In this case, the UV control surface will match the main surface start and hence will have the tile status for all compression units from the previously tile row aligned main surface address.

Restrictions
• Only Y tiling is supported. • 90/270 rotation not supported. • Async flips not supported.

Decompression Programming

When compressed media targets are presented to display, the media decompression must be enabled. Along with main surface programming, the following additional programming is required for both Y and UV planes individually.

- **Decompression Enable**

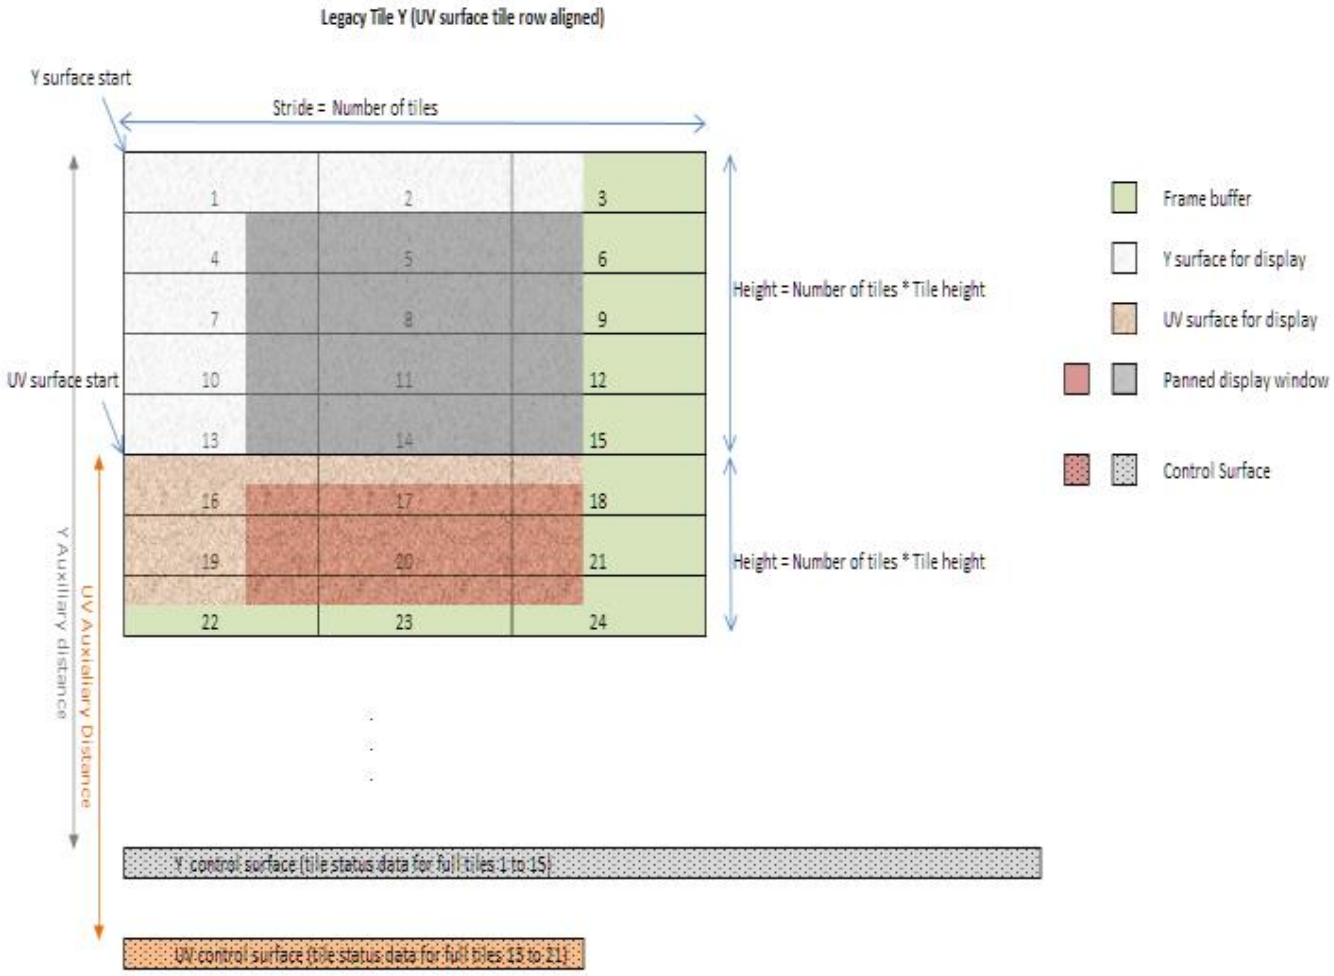
  Decompression is enabled by programming the 'Media Decomp' bit in the PLANE_CTL register.

- **Control Surface Distance**

  The start of the control surface is programmed as the distance in bytes from the start of the main surface in the PLANE_AUX_DIST register. The control surface must always be placed after (not necessarily immediately) the main surface and must be 4K page aligned.

  Control surface stride is not used for media compression.

  Y and UV control surfaces must both be 4k aligned.



Plane Rotation Programming

This topic provides programming information for plane rotation.

The 180 rotation mode is unchanged and will continue to use the same programming. In the 180 rotation mode display hardware is responsible for walking the pages in the reverse order. The cacheline walk within the page is also reversed. The 90 and 270 rotation modes require more complicated page walk mechanism. The page walk is made transparent to the hardware by providing a different set of page translations (remapped GTT) for the same rendered surface. The remapping completely abstracts the page walk away from the hardware and the hardware walks the pages as if there is no rotation. Hardware is still responsible for handling the the walk within the page appropriately. Also, the 90, 270 Rotation requires a new parameter - surface height. The changes needed in the driver programming is discussed below.

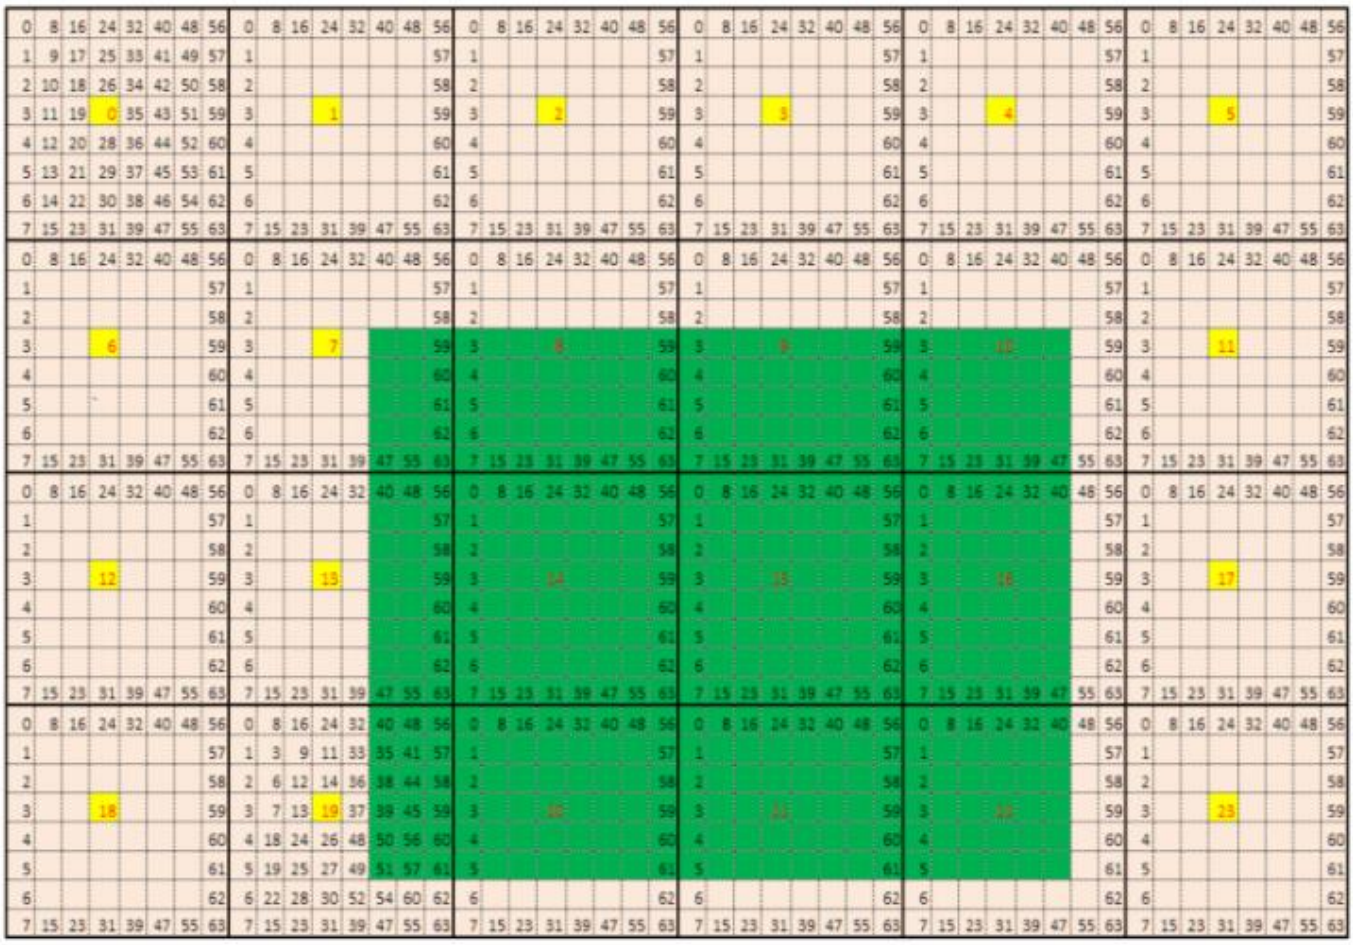
90 Rotation

For the 90 rotation programming, the plane parameters must use the following mapping

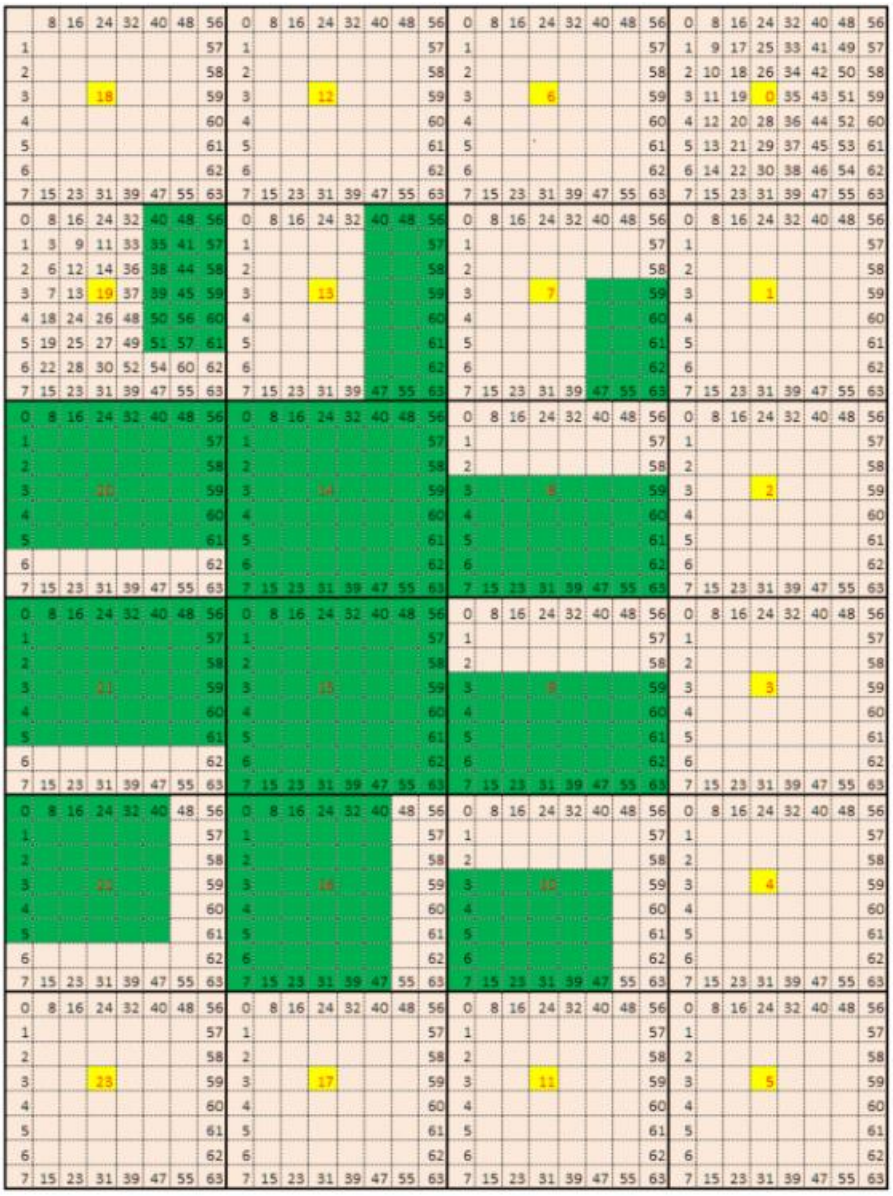
- Base address = New address (remapped GTT)

- Stride = Surface height in tiles
- Plane Width = Plane Height
- Plane Height = Plane Width
- X offset = (Surface height in tiles * tile height) - Plane Y offset - Plane Height *[Note: the calculated X offset will always be >= 0 since Plane Y Offset + Plane Height <= Surface Height in lines]*
- Y offset = X offset
- Driver can enable the Scaler, as needed, to fit the rotated content in to the pipe active display area.

Sample frame buffer surface



Page access sequence in the rotated 90 mode



Example

Let us assume the following display programming for a single pipe - single plane, Y tiled, non-rotated, 1920 x 1200, 4Bpp with the plane panned (100, 150), covering full active area and scaler not enabled.

GTT mapping

Here is a sample GTT mapping for 90 rotation mode.

Original GTT

Assumed Surface base = 0x200000

0x200000 = page 0

0x201000 = page 1

0x202000 = page 2

0x203000 = page 3

...

Remapped Display GTT - 90 rotation

Assumed new Surface base = 0x400000

0x400000 = page 18

0x401000 = page 12

0x402000 = page 6

0x403000 = page 0

Register programming for non-rotated scenario

- *PLANE_SURF->Surface Base Address = 0x200000*
- *PLANE_STRIDE->Stride = 60* [(1920 * 4)/128] [(width *bpp)/tile width]
- *PLANE_SIZE->Width = 1920*
- *PLANE_SIZE->Height = 1200*
- *PLANE_OFFSET->Start X Position = 100*
- *PLANE_OFFSET->Start Y Position = 150*
- *Surface Height in tiles (assumed) = 50 (allocated surface height in number of scan lines/tile height. For plane height = 1200, the surface height should be a minimum of 38 tiles (ceiling (1200/32). When panning is used, the rendered frame buffer surface will be larger than the plane size. Here, let us assume that the rendered surface height in tiles = 50).*

The programming changes to following for a 90 rotation scenario

- *PLANE_SURF->Surface Base Address = 0x400000* [uses remapped GTT]
- *PLANE_STRIDE->Stride = 50* [Surface height in tiles (assumed earlier)]
- *PLANE_SIZE->Width = 1200* [non-rotated Height]
- *PLANE_SIZE->Height = 1920* [non-rotated Width]
- *PLANE_OFFSET->Start X Position = 250* [(50*32)-150-1200] [(Surface height * tile height) - non rotated Y position - non rotated Height]
- *PLANE_OFFSET->Start Y Position = 100* [non-rotated X position]

The scaler should be programmed appropriately to fit the rotated plane in the pipe active area and the window position should be adjusted if it is desired to maintain the same apparent position on a physically rotated display.

270 rotation

Uses the same GTT remapping and register programming as 90 rotation mode with the Plane control register rotation mode set as 270.

NV12 (YUV 420) rotation

For NV12 90/270 rotation, the Y and UV surfaces should be treated as separate surfaces and thus the GTT remapping for rotation should be done separately.

Display Buffer Programming

Display Buffer Allocation

Allocation of the display buffer is programmable for each display plane, using the buffer start and buffer end values in **PLANE_BUF_CFG**.

Proper display buffer allocation is important for Display hardware to function correctly. Optimal allocation provides better display residency in memory low power modes. Display Buffer allocation must be recalculated and programmed when pipes/planes get enabled or disabled.

Display Buffer Size

Buffer Count	Total Buffer Size	Total Buffer Blocks	Blocks Available for Programming
2	1 MB (512 KB per buffer)	2048 (1024 per buffer)	2048

Each display buffer block is 8 cache lines.

Allocation Requirements

Allocation must not overlap between any enabled planes.

A minimum allocation is required for any enabled plane. See Minimum Allocation Requirements below.

A gap between allocation for enabled planes is allowed.

The allocation for enabled planes should be as large as possible to allow for higher watermarks and better residency in memory power saving modes.

Minimum Allocation Requirements

Allocation for each enabled plane must meet these minimum requirements.

Planes using Linear or X tiled memory formats must allocate a minimum of 8 blocks.

Planes using Y tiled memory formats must allocate blocks for a minimum number of scanlines worth of data. The formula and table of minimum scanlines is below.

Y tiled minimum allocation = Ceiling [(4 * Plane source width * Plane Bpp)/512] * MinScanLines/4 + 3

Plane Bpp	Minimum Scanlines for Y Tile	
	0/180 Rotation	90/270 Rotation
1	8	32
2	8	16
4	8	8
8	8	4

YUV 420 Planar Surface Format	Bpp
NV12	1 Bpp for Y and 2 Bpp for UV
P0xx	2 Bpp for Y and 4 Bpp for UV

Multi-Buffer Enabling and Allocation Requirements

There are two display buffers DBUF_S1 and DBUF_S2.

Display Buffer	Buffer Start	Buffer End
DBUF_S1	0	1023
DBUF_S2	1024	2047

Enable DBUF_S1 with the display initialization sequence so it will be always available for VGA and backwards compatibility. Enable DBUF_S2 when any planes are allocated to it as per the following table.

The table ensures that pipes are using the closest DBUF when there are multiple pipes enabled.

Pipe and DBUF ordering: PipeD - DBUF_S2 - PipeC - PipeA - DBUF_S1 - PipeB

When a pipe is allowed to allocate from 2 DBUFs, a plane on that pipe may use allocation that straddles the 2 DBUFs.

Pipe D Planes DBUF Allocation	Pipe C Planes DBUF Allocation	Pipe A Planes DBUF Allocation	Pipe B Planes DBUF Allocation	Pipes with Enabled Planes
N/A	N/A	N/A	N/A	None or VGA
N/A	N/A	S1+S2	N/A	A
N/A	N/A	N/A	S1+S2	B
N/A	N/A	S2	S1	A+B
N/A	S1+S2	N/A	N/A	C
N/A	S2	S1	N/A	A+C
N/A	S2	N/A	S1	B+C
N/A	S2	S1	S1	A+B+C
S1+S2	N/A	N/A	N/A	D
S2	N/A	S1	N/A	A+D
S2	N/A	N/A	S1	B+D
S2	N/A	S1	S1	A+B+D
S2	S1	N/A	N/A	C+D

Pipe D Planes DBUF Allocation	Pipe C Planes DBUF Allocation	Pipe A Planes DBUF Allocation	Pipe B Planes DBUF Allocation	Pipes with Enabled Planes
S2	S2	S1	N/A	A+C+D
S2	S2	N/A	S1	B+C+D
S2	S2	S1	S1	A+B+C+D

Basic Allocation Method

These are basic methods that can be used for single and multi-pipe modes. For optimal power usage, the display driver can choose to use more advanced allocation techniques as desired.

Example Method 1:

Single Pipe

Enable display buffer(s). Refer to DBUF_CTL register for display buffer enabling.

If only DBUF_S1 is enabled

TotalBlocksAvailable = 1024

else if both DBUF_S1, DBUF_S2 enabled

TotalBlocksAvailable = 2048

Allocate a fixed number of blocks to cursors and then allocate the remaining blocks among planes, based on each plane's data rate.

BlocksAvailable = TotalBlocksAvailable

1. Allocate 32 blocks for cursor

   The driver frequently enables and disables the cursor or changes the cursor pixel format. Fixed allocation is preferred for cursor to minimize the buffer re-allocation. More allocation might be required to support deeper low power states (based on the results of watermark calculations).

   CursorBufAlloc = 32

   BlocksAvailable = BlocksAvailable – 32

2. Check for minimum buffer requirement

   For each enabled plane

   If Y tiled

   MinScanLines = Look up minimum scanlines needed from the table

   *PlaneMinAlloc = Ceiling [(4*Plane width*Bpp)/512] * MinScanLines/4 + 3*

   Else

   PlaneMinAlloc = 8

If sum of PlaneMinAlloc > BlocksAvailable

Enable DBUF_S2

BlocksAvailable = 2048 - CursorBufAlloc

If sum of PlaneMinAlloc > BlocksAvailable

Error - Display Mode can't be supported.

The driver can change the number of enabled planes or the plane configuration and rerun the algorithm.

3. Calculate Relative Data Rate for planes

   In this step the driver may want to use the expected maximum plane source sizes so it does not have to reallocate for a plane that is changing size.

   For each enabled plane

   If PlaneScalerEnabled

   *PlaneScaleFactor = (Plane width/Scaler window X size) * (Plane height/Scaler window Y size)*

   Else

   PlaneScaleFactor = 1

   *PlaneRelativeDataRate = Plane height * Plane width * plane source bytes per pixel * PlaneScaleFactor*

4. Allocate blocks for enabled planes as per the Data rate ratio.

   For each plane that needs allocation (PlaneBlockAllocFinal == false)

   *PlaneBufAlloc = floor (BlocksAvailable * PlaneRelativeDataRate/Sum of PlaneRelativeDataRate of all planes that need allocation).*

   *floor - rounds down to an integer value dropping the fractional part.

5. Adjust for minimum allocation requirement

   AdjustmentRequired = false

   For each plane needs allocation (PlaneBlockAllocFinal == false)

   If PlaneBufAlloc < PlaneMinAlloc

   AdjustmentRequired = true

   PlaneBufAlloc = PlaneMinAlloc

   PlaneBlockAllocFinal = true

   BlocksAvailable = BlocksAvailable - PlaneMinAlloc

   If AdjustmentRequired = true

   Go back to step 4

Multi-Pipe Option 1:

Enable both display buffers DBUF_S1 and DBUF_S2.

TotalBlocksAvailable = 2048

NumPipes = Total number of display pipes in the hardware

Allocate a fixed number of blocks to cursors, allocate 1/*NumPipes* of the remaining blocks to each pipe, then calculate each pipe individually as in the Single Pipe case.

1. Allocate 8 blocks for cursor per pipe

   The driver frequently enables and disables the cursor or changes the cursor pixel format. Fixed allocation is preferred for cursor to minimize the buffer re-allocation. More allocation might be required to support deeper low power states (based on the results of watermark calculations).

   For each enabled cursor

   CursorBufAlloc = 8

   *BlocksAvailable = TotalBlocksAvailable - (8 * NumPipes)*

2. Distribute the blocks equally among the pipes

   BlocksAvailable = BlocksAvailable/NumPipes

3. Assign blocks to the planes

   For each pipe

   Perform Single Pipe sequence, starting from step 2.

Multi-Pipe Option 2:

Allocate a fixed number of blocks to cursors, use the Single Pipe case for all the other planes across all pipes.

Example Method 2:

This allocation is based on the Watermark calculations and helps to distribute the buffer more optimally to achieve consistent latency levels supported across all planes.

- For each enabled plane, calculate buffer allocation needed for all Latency levels 1 to 7.
- Calculate the total buffer allocation needed for each latency level by adding the individual allocation of all enabled planes.
- Choose the max latency level that can be supported with the available display buffer. For each enabled plane, program/enable all watermarks up to that latency level.
- Allocate the buffer to the planes as required by the latency level chosen.

Use method 1 to allocate any remaining buffer.

Buffer Allocation Re-distribution

When an additional pipe is getting enabled, or an existing pipe requires more buffer to support a new mode or is disabled, buffer reallocation may be necessary for proper display functionality. Whenever a portion of the allocated buffer is taken away from one pipe and allocated to a different pipe, the following sequence should be followed to make sure that there are no buffer allocation overlaps at any point of time.

1. *For each pipe whose allocation is reduced*
    a. *Program the new buffer allocation.*
    b. *Wait for VBlank of that pipe for new allocation to update.*
2. *For each pipe whose allocation is increased*
    a. *Program the new buffer allocation.*
    b. *Wait for VBlank of that pipe for new allocation to update.*

Display Buffer Allocation and Watermark Programming Prior to OS Boot

Basic programming of the display buffer and watermarks to allow limited display usage prior to OS boot:

This will not allow package power saving states.

Supported usages:

- Up to 4 pipes enabled at once
- Up to one universal plane enabled per pipe. No cursor.
- Linear or Xtile memory
- Any RGB frame buffer pixel format 32bpp or less, without compression
- Any supported screen resolution
- Downscaling less than or equal to 12.5%

Enable DBUFs following the Multi-Buffer Enabling and Allocation Requirements.

Allocate 160 blocks per pipe

- Pipe A: 0-159, Pipe B: 160-319, Pipe C: 320-479, Pipe D: 480-639
- PLANE_BUF_CFG_<plane number>_A = 0x009F0000
- PLANE_BUF_CFG_<plane number>_B = 0x013F00A0
- PLANE_BUF_CFG_<plane number>_C = 0x01DF0140
- PLANE_BUF_CFG_<plane number>_D = 0x027F01E0

Set level 0 watermarks for any enabled plane to 160 blocks and 2 lines.

- PLANE_WM_<plane number>_<pipe>_0 = 0x800080A0

The higher level watermarks for any enabled plane must have bit 31=0 to keep the low power watermarks disabled.

VGA

The VGA Control register is located here. The VGA I/O registers are located in the VGA Registers document.

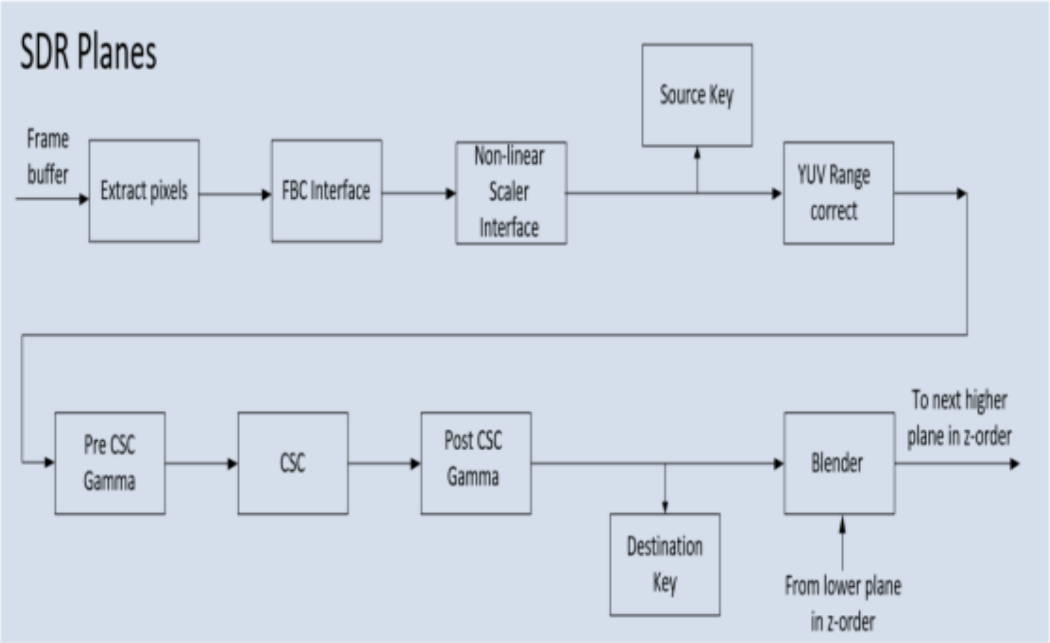
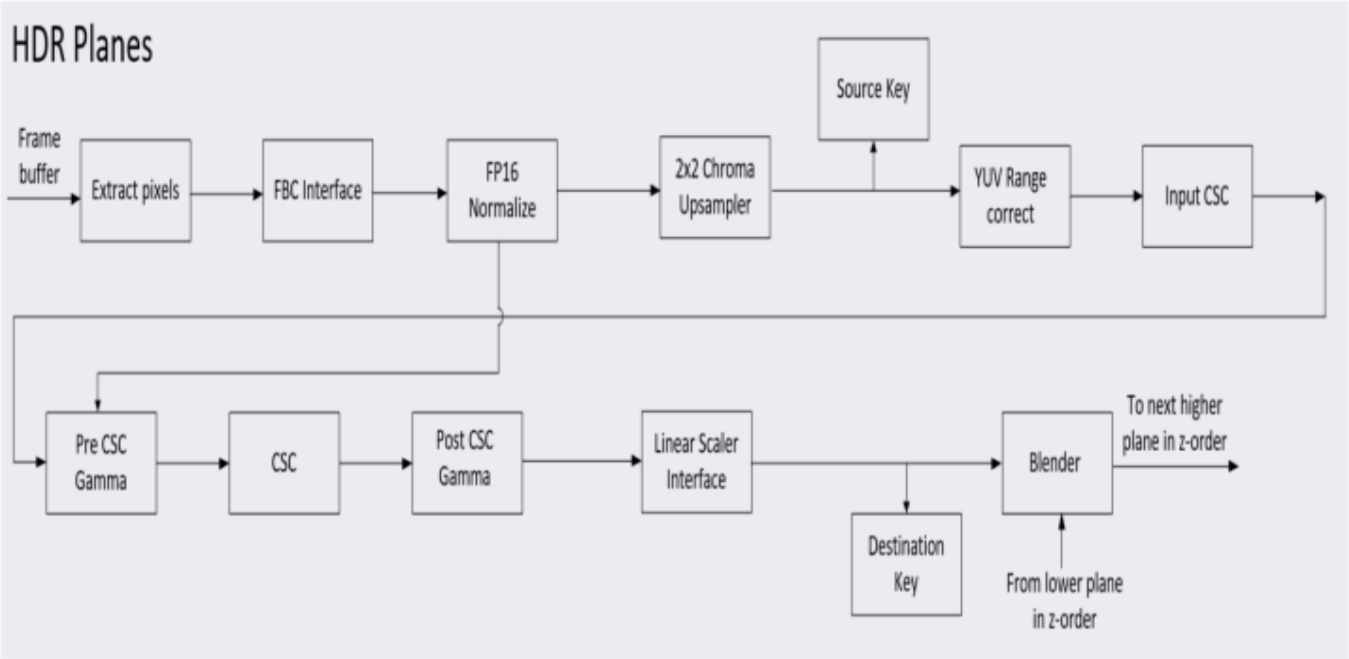
Many of the plane control active registers will be updated on the vertical blank or when pipe is disabled, after the surface base address register is written, or when the plane is not yet enabled, providing an atomic update of those registers together with the surface base address register.

Data Flow Through the Plane





FBC not on all planes or pipes.

HDR planes have higher bit precision throughout the processing stages.

PIPE_MISC HDR Mode must be enabled to get the higher precision output from the HDR planes, bypassing the SDR planes in blending.

Planes 1-3 are the HDR planes. The other planes are SDR planes.

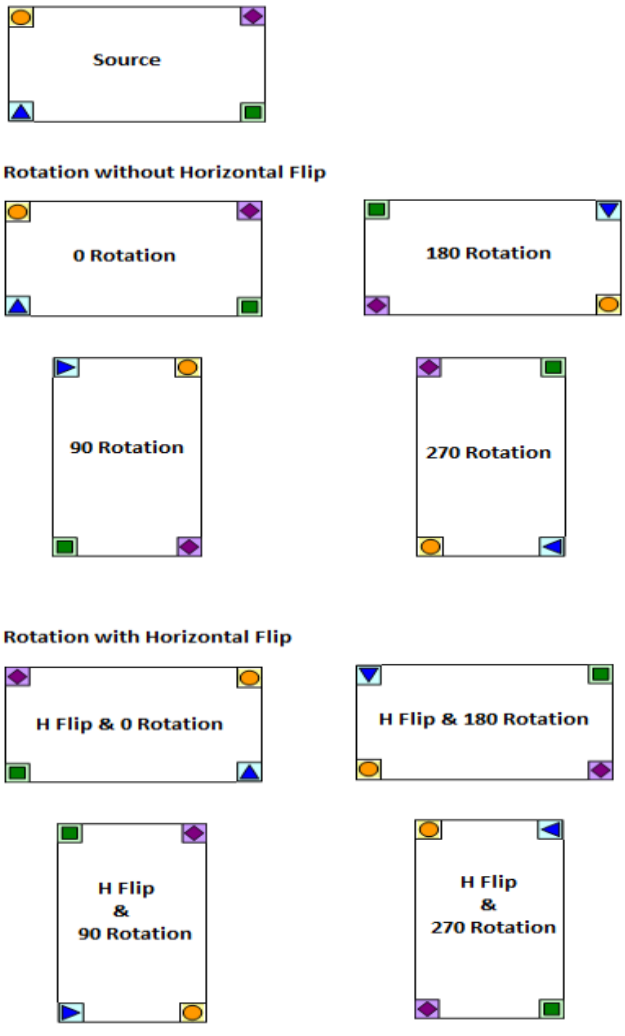
Horizontal Flip

When plane horizontal Flip is enabled with rotation, the horizontal flip operation is logically performed first followed by the rotation operation. The sample results are shown below.



DSC

DSC Source Policies

Port Type	Source Policy
eDP	DSC output BPP is as defined in DPCD. If eDP Sink reports capability for multiple link rates, choose the optimal link rate based on bandwidth calculations.
DP	DSC is enabled only when link bandwidth requires it. DSC output BPP is set to the highest possible value within link bandwidth.
HDMI	DSC BPP and link bandwidth are selected as per the Specification (VIC).

Transport mandatory DSC features

The following features are options at DSC level but are mandatory at transport level.

Design requirements

Design parameter	RGB/YUV 444	YUV 422	YUV 420
slice width	no restriction	multiple of 2	multiple of 2
	minimum = 18	minimum = 36	minimum = 36
slice height	no restriction	no restriction	multiple of 2
Pixels in Slice	Must be >= 15000	Must be >= 30000	Must be >= 30000

VDSC compression engines do not support interlaced mode of operation for any transport protocol.

Below are the list of DSC encoder specific registers in Bspec. There are 2 copies of these registers, one for each VDSC engine.

Register List
PIPE_DSS_CTL1
PIPE_DSS_CTL2
DSC_PICTURE_PARAMETER_SET_0 Field vbr_enable setting as "1" is not supported.
Set 0 Field "Allow double buffer update disable" is not from DSC standard.

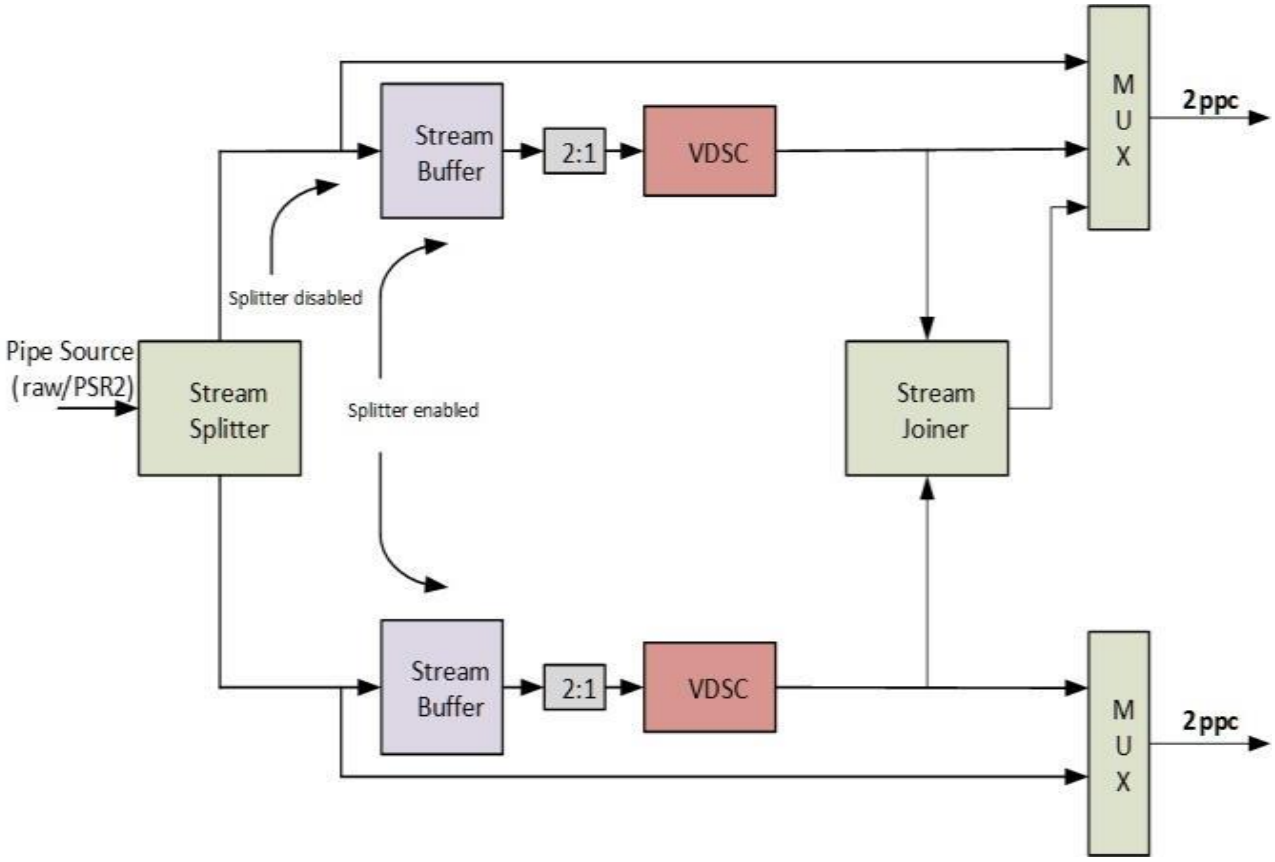
VDSC

VDSC feature compresses the raw pixel bytes into compressed byte stream as per VESA DSC specification. The pixel stream can be injected into VDSC as shown below at any of the 3 different input ports. In a typical use case, VDSC can split the pipe frame into left/right (front/back in MIPI) halves and uses 2 VDSC engines to compress each half and then joins the compressed byte streams from 2 VDSC engines into a single compressed byte stream. Each VDSC engine is configured with its own PPS register set.

Each VDSC operates with 1 ppc throughput and this becomes a limitation when the pixel clock is higher than the VDSC clock (cdclk). These cases are supported by running 2 VDSC engines in parallel, effectively realizing 2ppc throughput.



The following datapath options are supported in the VESA based compression engine. The top mux output is designated as left (front) and bottom mux output is designated as right (back) in the case of split streams. Stream joiner output can only feed into the top mux output. If the input frame is divided into an even number of slices (say, N) by enabling the splitter, then the corresponding branch parameters such as picture width and slice width need to be adjusted accordingly. For example, if the input frame (pipe source in the diagram above) is divided into 4 slices per scanline then the slice width on each branch will be HACTIVE/4 and the picture width on each branch will be HACTIVE/2.

Compression Engine Modes of Operation

Mode	Splitter Enabled	VDSC Enabled	Joiner Enabled	Notes
Bypass mode	No	No	No	Non-PSR2 stream eDP PSR2: same as bypass except for input source to DSC engine Output on left VDSC branch only.
VDSC enabled mode	No	Yes	No	MIPI: see the MIPI table below Pixel rate is limited w/o splitter, see resolution support page Output on left VDSC branch only.
Split mode	Yes	No	No	Required for eDP CoG/MSO without VDSC Required for MIPI dual link (front/back and interleaving) w/o VDSC Output on left and right VDSC branches.
Split/Compress mode	Yes	Yes	No	Required for eDP CoG/MSO with VDSC Required for MIPI dual link with VDSC Output on left and right VDSC branches.
Joiner enabled mode (small joiner)	Yes	Yes	Yes	Cannot work with CoG Output on left VDSC branch only.

Big Joiner

The above DSC engine can achieve compression over multiple pipes to compress 8K image size as shown below. A frame can be divided and processed by 2 adjacent pipes, compressed by their associated VDSC engines, then the compressed pixels streams from 2 pipes will be joined into a single compress pixel stream. In this 8K scenario the frame is compressed by a total of 4 VDSC engines in parallel. We have separate PPS DIP packet defined on per transcoder basis.

In the case of big joiner mode, video timings are determined by the attached transcoder.

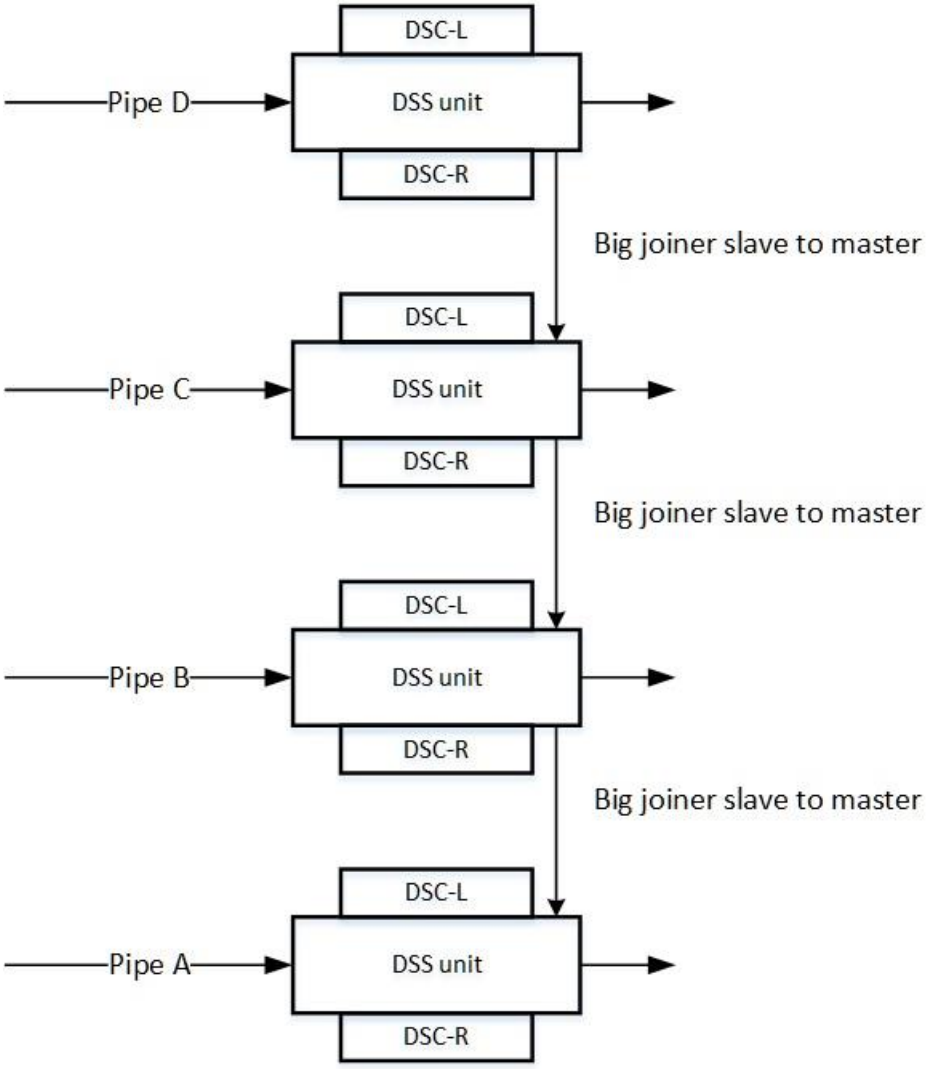
Big joiner mode cannot be used if compression is bypassed in VDSC.

Big joiner mode cannot be used if small joiner is not enabled.

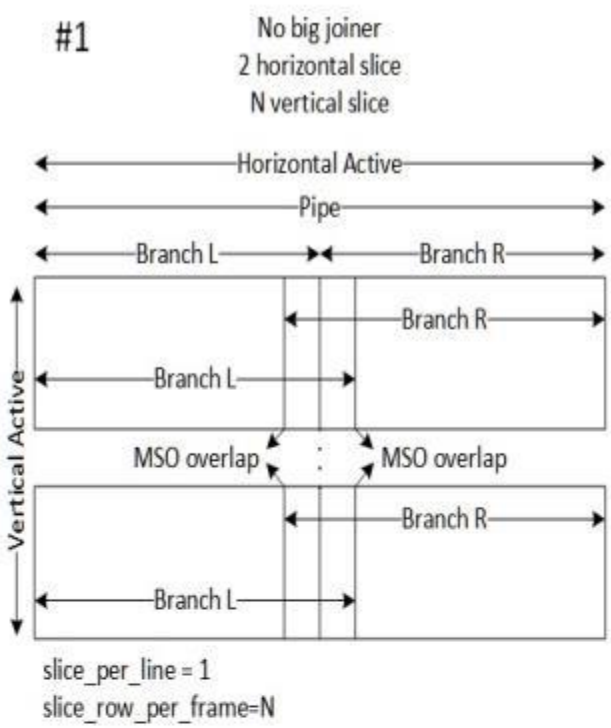
The front-end display requirements in the case of big joiner mode are same as in dual port 8K configuration. Audio works same as in other display configurations.

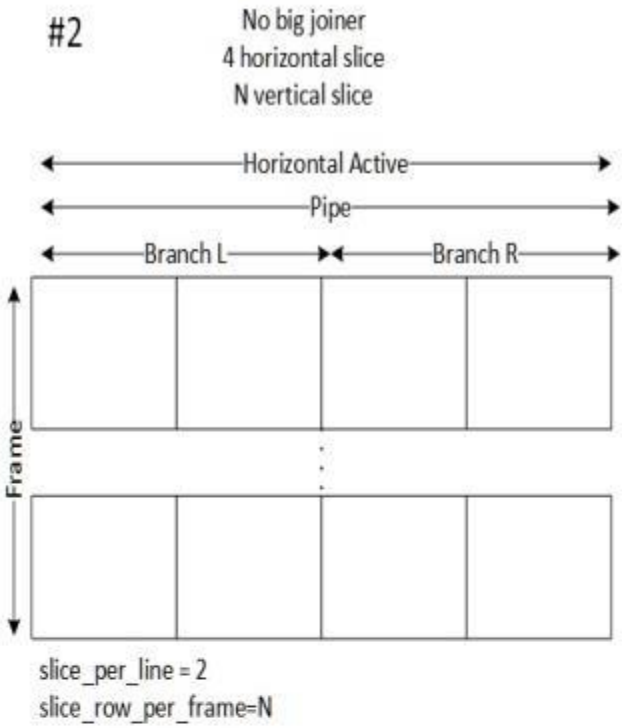
In DSC:

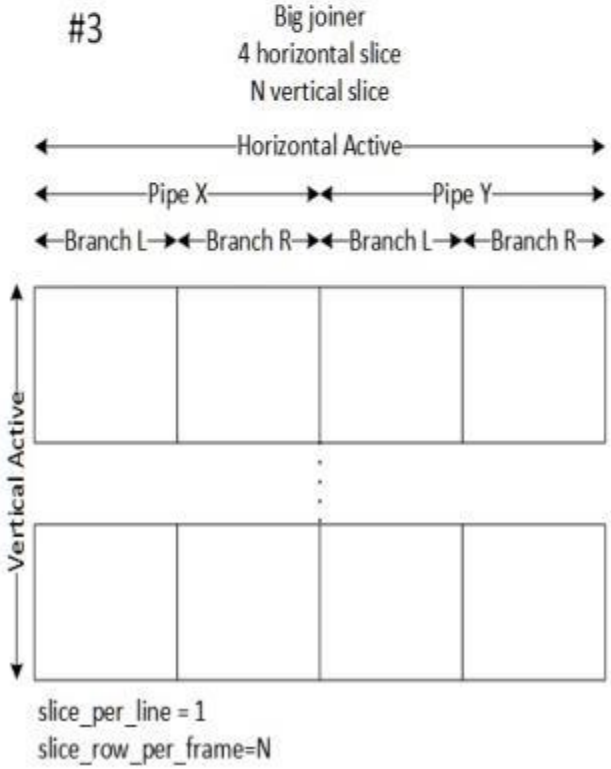
- Compression engine is moved to the pipe and all pipes support VDSC.
- Any two adjacent pipes can be joined together as shown below to support even higher resolutions (example: 8k).

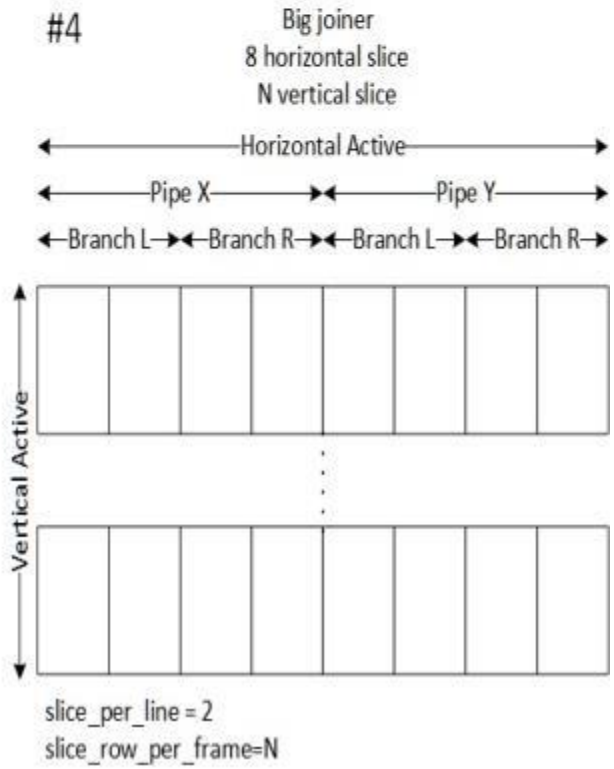


VDSC Slice Options









- Each DSC branch supports 1 or 2 horizontal slices.
- Both branches must be enabled with small joiner, so pipe output is 2 or 4 horizontal slices
- Final port output without big joiner (1 pipe alone) is 2 or 4 horizontal slices.
- Final port output with big joiner (2 pipes combined) is 4 or 8 horizontal slices.
- For non-MSO use cases, Horizontal active must be an integer multiple of slice width in pixels. For MSO use cases, overlap pixels need to be included.
- Each DSC branch slice_per_line = number of horizontal slices this DSC branch is processing = number of horizontal slices for full frame / number of DSC branches enabled for this video stream
- Minimum vertical slice (slice row) count is 1.
- Maximum vertical slice (slice row) count is 4095.
- Vertical active must be an integer multiple of slice height in lines.
- Each DSC branch slice_row_per_frame = number of vertical slices = vertical active / slice height
- VDSC spec implies that 108 lines is an optimal slice height, but any size can be used as long as vertical active integer multiple and maximum vertical slice count requirements are met.
- Each DSC branch pic_height = vertical active
- non-MSO: Each DSC branch pic_width = horizontal active / number of DSC branches enabled for this video stream. PPS transmitted to receiver must use full width.
- MSO: Each DSC branch pic_width = horizontal active / number of DSC branches enabled for this video stream + overlap pixels. PPS transmitted to receiver must use full width.

Programming considerations and restrictions

DP 1.4a RESTRICTION: For every VDSC instance, active video height must be an integer multiple of slice height.

DSC 1.2a slice height recommendation: Based on empirical data the optimal slice height is 108.

The default slice height can be set to a value that satisfies the above as follows.

slice height = ~108 and picture height = N * slice height where N is an integer.

Below are the checklist items to program VDSC.

- DSS registers to configure VDSC branches
- Picture parameter set register programming for each VDSC branch
- Link M/N programming for compression enabled use cases
- Transcoder data island packet for PPS

Note that there is no implicit order to program compression engine's PPS and DSS registers other than that they need to be programmed prior to a VBLANK.

DSI Configuration	Splitter	Joiner	DSC to DSI Mapping	Notes
Single link - single pipe	Yes	Yes	DSC (L) + DSC (R) -> DSIx	Small joiner output always on left VDSC branch.
Dual independent links	Yes	Yes	PipeX -> DSC (L) + DSC (R) -> DSI0 PipeY -> DSC (L) + DSC (R) -> DSI1	Each pipe will instantiate its own DSS unit to drive pixels to one of the DSI ports.
Dual link - single pipe	Yes	No	Pipe A DSC(L) - DSI0 Pipe A DSC(R) - DSI1	Both ports must be bound to the same pipe AND DSI0 must be configured for Port Sync Mode. Only pipe A can be used.

The following rules determine the highest output bpp that the design can support in various compression scenarios.

Pipe BW check: Pixel clock < PPC * CDCLK * number of pipes

Link BW check: output bpp < number of lanes * DDICLK * 8 / Pixel clock -- DisplayPort

Big joiner BW check
output bpp <= PPC * CDCLK * 24 bits / Pixel clock

Small joiner RAM check: output bpp <= joiner RAM (bits) / Horiz. width

Note that horizontal width has to account for overlap and dummy pixels in CoG use cases.

Greatest allowed DSC output BPP = INT(MIN (output BPP from Link BW check, output BPP from Big joiner BW check, output bpp from small joiner RAM check))

For cases where FEC is enabled, pixel clock is replaced by pixel clock/0.972261 in the above calculations.

Smaller Joiner RAM Size
7680 bytes per pipe, 15360 bytes for two joined pipes Example: CDCLK = 336 MHz, DDICLK = 810 MHz, PPC = 2 pixels/cycle, DP lanes = 4, input Pixel BPP = 30, Pixel clock (CVT) = 1026 MHz, Horiz. width = 3840 pixels Greatest allowed DSC output BPP = INT(MIN (output BPP from Link BW check, output BPP from Big joiner BW check, output bpp from small joiner RAM check)) = INT(MIN (25.26, 15.71, 32)) = INT(15.71) = 15

Design Support

With dual pipe configuration, HW is capable of supporting maximum of 8 slice per line. (Big joiner mode and dual pipe cases)

With single pipe configuration, HW is capable of supporting maximum of 4 slice per line. (Small joiner and single pipe cases)

Input pixel format	bpp	Max input width	Output bits per pixel[1]	DSC Standard
RGB444	24 and 30 bpp	5120 pixels per pipe, 8192 across two joined pipes	8 to 23[2]	v1.1
RGB444	24, 30 and 36 bpp	5120 pixels per pipe, 8192 across two joined pipes	8 to 23[2]	v1.1

[1]BPP at max input width

[2]Use the rules above to calculate maximum bpp

[3]FEC is enabled. See the DDI FEC section for FEC support.

[4] Fractional bpp mode enabled.

[5] Some joiner modes limit output bpp to half of input bpp.

Transcoder

Transcoder DSI Function

The following registers are specific to the MIPI Display Serial Interface (DSI) ports. Both DSI Controller (i.e. the DSI Protocol Layer) and D-PHY (i.e. the DSI Physical Layer) registers are listed here.

Registers
DSI specific functional configuration registers:
TRANS_DSI_FUNC_CONF
Control for DSI protocol timers:
DSI_PWAIT_TO
DSI_HTX_TO
DSI_LRX_H_TO
DSI_TA_TO
DSI_CALIB_TO
DSI interrupt registers:
DSI_INTER_MSK_REG
DSI_INTER_IDENT_REG
DSI timing control registers:
DSI_CLK_TIMING_PARAM
DSI_DATA_TIMING_PARAM
DSI_TRIG_TX_TIME

Registers
DSI_ESC_CLK_DIV
DSI_T_INIT_PRIMARY
DSI_T_WAKEUP
DSI_IO_MODECTL
D-PHY control registers (Located in Combo-PHY):
DPHY_CLK_TIMING_PARAM
DPHY_DATA_TIMING_PARAM
DPHY_TA_TIMING_PARAM
DPHY_TRIG_EXT
DPHY_ESC_CLK_DIV
DSI command transmit/receive control:
DSI_CMD_FRMCTL
DSI_CMD_TXCTL
DSI_CMD_RXCTL
DSI_LP_MSG
DSI receive data (header and payload):
DSI_CMD_RXHDR
DSI_CMD_RXPYLD
DSI transmit data (header and payload):
DSI_CMD_TXHDR
DSI_CMD_TXPYLD
DC state control:

The following registers are common across all ports, in which the DSI port is one of them.

Registers
Transcoder Control
TRANS_CONF
TRANS_STEREO3D_CTL
Transcoder Timing
TRANS_HTOTAL
TRANS_HSYNC
TRANS_VTOTAL
TRANS_VSYNC
TRANS_SPACE

Transcoder DDI Function
TRANS_DDI_FUNC_CTL
TRANS_DDI_FUNC_CTL2

Burst Mode Considerations

The MIPI DSI Burst Mode is a Video Mode concept where the transcoder delivers pixels to the Panel at a higher bandwidth than the pixel rate required to maintain the display timings. Note that there is no concept of Burst Mode in Command Mode since the Host is not maintaining the display timings and should be sending the pixels to the Panel as fast as possible.

Burst mode can be achieved in Video Mode by one of the following methods:

1. Program the Link speed to the minimum frequency needed to satisfy the resolution pixel rate and compress the pixel stream. This is assuming the minimum frequency is less than or equal to the maximum frequency supported.
2. Program the Link speed to a supported frequency that will generate a pixel rate greater than what is required to satisfy the resolution pixel rate

It is important to understand that the DSI transcoder uses the Horizontal Total, Sync Start, and Sync End programming (programmed in terms of pixels) to calculate the number of 1X clocks needed to attain the desired H. timings to the Panel. Hardware uses the following equation to perform this conversion:

H. Time (in 1X clocks) = ceiling((H. Size * bpp) / (Operating Width * 8)

Some notes on this equation:

1. The "bpp" term is the pixel format being transmitted to the Panel
2. 24bpp should be used for compressed pixel streams
3. Hardware does not know what frequency the Link is running at, so it is the responsibility of Software to program the Link frequency appropriately to meet the desired pixel rate

In a non-Burst Mode of operation, Software will program the Link speed to a frequency that will generate the pixel rate on the Link needed to satisfy the Panel's resolution. In this case the H. timings that Hardware calculates will correlate directly to the H. timings (in pixels) that Software programs. In other words, the 1X clock period is equal to the pixel rate needed for the resolution. However, for a Burst Mode method where the Link speed is running at a higher frequency, the period of the 1X clock is going to be less than the theoretical pixel rate period, so Software will need to account for that by adjusting the H. Total, Sync Start, and Sync End timings. In other words, the H. timings will need to be increased to offset the faster 1X clock frequency.

Calculating the Horizontal burst timings in pixels is simply taking the normal H. timing parameter and multiplying it by the burst ratio, where the burst ratio is:

Burst Frequency Ratio = $f_{8X\ Burst}$ / $f_{8X\ Minimum}$

H. Timing Burst = ceiling(H. Timing Non-Burst * Burst Frequency Ratio)

Example:

H. Active	3072	pixels
H. Blank	160	pixels
H. Front Porch	48	pixels
H. Sync	32	pixels
V. Active	1920	lines
V. Blank	55	lines
Frames per Second	60	fps
Pixel Format	18	bits per pixel
Operating Width	4	lanes
Pixel Frequency	382.99	Mega pixels per frame
8X Min Frequency	1723	MHz
8X Burst Frequency	2500	MHz
Burst Frequency Ratio	1.451	

H. Total Burst= ceiling((3072 + 160) * 1.451) = 4690 pixels

H. Sync Start Burst = ceiling((3072 + 48) * 1.451) = 4527 pixels

H. Sync End Burst = ceiling((3072 + 48 + 32) * 1.451) = 4574 pixels

Programming Horizontal Timings in Video Mode when operating with compressed pixels

When a Horizontal resolution requires a Link speed that is greater than the maximum supported frequency, then compression can be used to reduce the Link speed to a frequency that is within a supported frequency. When the transcoder is operating within this regime, then similar to the Burst Mode described above, the Horizontal timings (H. Total, Sync Start, and Sync End) will need to be adjusted to account for a Link speed that is slower than what the non-compressed Link speed would need to be running at.

H. Timing Compressed = ceiling(H. Timing Non-Compressed * Compression Frequency Ratio)

Compressed Frequency Ratio = $f_{8X\ Compression}$ / $f_{8X\ Non\text{-}Compressed}$

Example:

H. Active	5120	pixels
H. Blank	160	pixels
H. Front Porch	48	pixels
H. Sync	32	pixels
V. Active	3200	lines
V. Blank	91	lines
Frames per Second	60	fps

Pixel Format	24	bits per pixel
Operating Width	4	lanes
Pixel Frequency	1042.5888	Mega pixels per second
8X Non-Cmp Frequency	6255.5	MHz
8X Cmp Frequency	2211.6	MHz
Cmp Frequency Ratio	0.3535	

H. Total Burst= ceiling((5120 + 160) * 0.3535) = 1867 pixels

H. Sync Start Burst = ceiling((5120 + 48) * 0.3535) = 1828 pixels

H. Sync End Burst = ceiling((5120 + 48 + 32) * 0.3535) = 1839 pixels

Determining Minimum Horizontal Blanking Regions

When in Video Mode, there are instances where the DSI controller does not have enough time to let the link transition to the LP state before the next HS burst. In these instances, the controller transmits a Blanking packet to keep the link in the HS state. However, Blanking packets are long packets (i.e. a packet header + payload + payload CRC) which means that the time between non-Blanking packet HS bursts (i.e. blanking regions) must be big enough to transmit a minimum sized Blanking packet.

Per the DSI specification, a long packet can carry zero bytes of payload (i.e. a packet header + payload CRC), but to simplify the hardware the transcoder expects the Blanking packet to carry a payload, and to keep the CRC boundary conditions to a minimum, the transcoder expects the payload to be **greater** than 4 bytes. Therefore, the minimum sized Blanking packet size that the controller can support is **11 bytes**.

In addition to the minimum Blanking Packet size, the blanking region must also account for protocol overhead (i.e. Pixel Packet header and payload CRC, and Sync Packets). The overhead within each horizontal blanking region differs slightly as shown within the following table.

Blanking Region	Size (Bytes)	Notes
Horizontal Front Porch	17	11B for minimum Blanking Packet, 6B for Pixel Packet header and payload CRC
Horizontal Sync	15	11B for minimum Blanking Packet, 4B for Horizontal Sync Start packet
Horizontal Back Porch	15-19	11B for minimum Blanking Packet, 4B for Horizontal Sync End packet, 4B for Pixel Packet header. Additional notes: 1. HW subtracts the Pixel Packet header from this region which is why the additional 4B is added to the minimum. 2. During Sync Event model the H. Sync End packet is not

Blanking Region	Size (Bytes)	Notes
		transmitted, so those 4B can be recovered.

Given the above, the number of byte clocks for a minimum sized blanking region can be calculated with the following equation.

Min Blanking Region (Byte clocks) = Ceiling(Region Size / Operating Width)

The following table lists the blanking region size in number of Byte clocks across the different operating widths:

Blanking Region	x1	x2	x3	x4
Horizontal Front Porch	17	9	6	5
Horizontal Sync / Horizontal Back Porch (Event)	15	8	5	4
Horizontal Back Porch (Pulse)	19	10	7	5

All the horizontal timings to the transcoder's timing generator is defined in pixels, so the minimum blanking region needs to be translated to the pixel domain. Recall from above, we have the following equation to translate the horizontal timings from the pixel domain to the number of 1x (i.e. Byte) clocks.

H. Time (in 1X clocks) = Ceiling((H. Size * Format bpp) / (Operating Width * 8))

Minimum H. Size (in pixels) = Ceiling((Min Blanking Region * Operating Width * 8) / Format bpp)

Where:

1. The equation is assuming the minimum horizontal pixel size result is one-based. Software will need to convert the size to zero-based when programming the horizontal timing registers
2. "H. Time (in 1X clocks)" = "Min Blanking Region"
3. The numerator of the equation will be a constant for each operating width and represents the blanking region size in terms of bits

Determining Vertical Blank in DBI

When operating in Command Mode (i.e. DBI) the DSI transcoder is not responsible for the timings to the Panel, but it does need to maintain some timings to the Display Engine. Specifically, the Display Engine requires a certain amount of Vertical blanking time to fetch enough of the image from memory to supply the required bandwidth to the DSI transcoder. The minimum Vertical blanking time (in lines) that the Display Engine needs is:

V. Blank = ceiling(400us / Line Time)

The time it takes the DSI transcoder to transmit a line (i.e. Line Time) is given by the following equation:

Line Time = # Byte clocks per line * Byte clock period

Line Time = [(H. Total * Bytes per Pixel) / Operating Width] * Byte clock period

Example:

H. Total = 4256 pixels

8X Clock = 2500 MHz = 3.2ns Byte clock period

Pixel Format = RGB888 = 3 Bytes per Pixel

Operating Width = 4

Line Time = [(4256 * 3) / 4] * 3.2ns = 10.214us

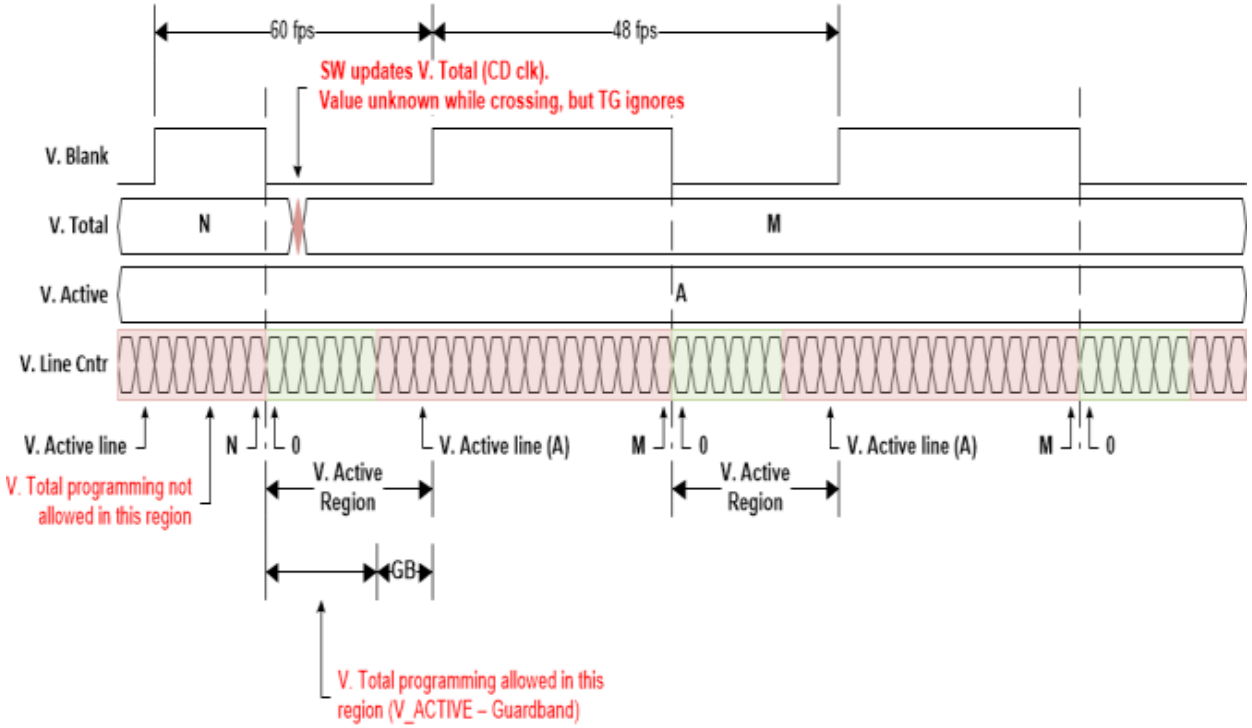
V. Blank = ceiling(400 / 10.214) = 40 lines

Extending Vertical Blank for Lower Frame Rates in DPI

A power saving option when the DSI transcoder is running in Video Mode is to extend the V. Blank time of the frames while running the clocks at the frequency required for the highest refresh rate. Normally, the transcoder expects the frame timings to be programmed before the timing generator is enabled and it expects the timings to remain unchanged while the timing generator is enabled, but for the Vertical timings if Software programs them at the right time, the transcoder should be able to handle the change seamlessly.

Specifically for this functionality, Software will be changing the V. Total field of the **TRANS_VTOTAL** register to either extend or reduce the V. Blank duration to get the desired frame rate. Since the DSI transcoder's timing generator only looks at this field when it is in the Vertical Back Porch, Software shall program the desired V. Total during the vertical active region.

To ensure the write to the TRANS_VTOTAL finishes before the V. Blank region, Software should ensure that it is not closer than 10 lines from V. Blank before issuing the write (i.e. lines 0 to (V. Active-10)). **Also, to ensure there is no glitching on the V. Active field of the TRANS_VTOTAL register, Software shall disable the byte enables for that portion of the register when re-programming the V. Total field.**



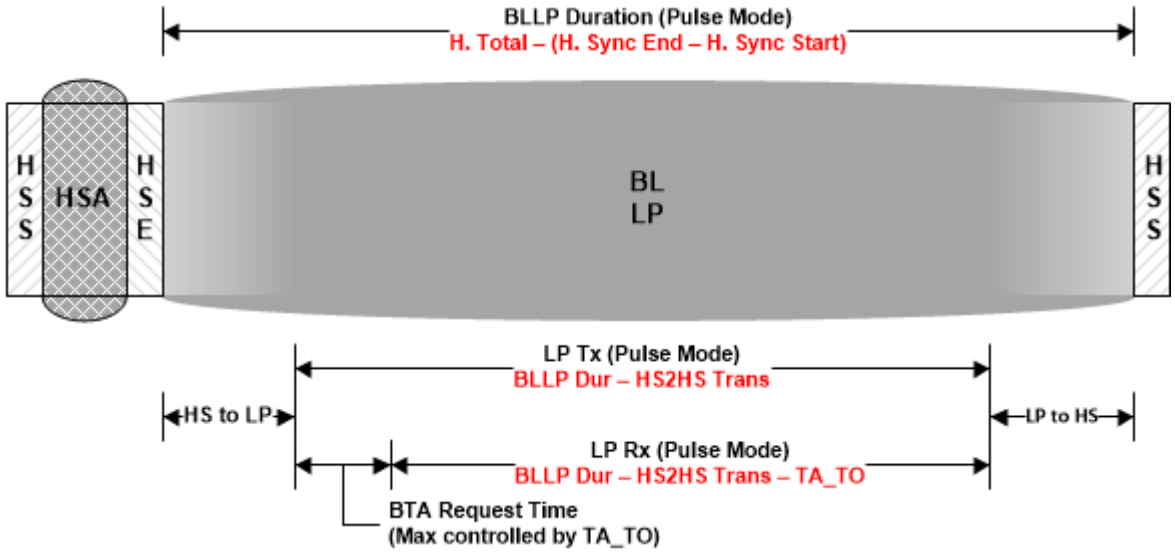
Performing LP Transactions in Video Mode

When in Video Mode the Host is responsible for transmitting the timing information to the Panel. Low Power communication is a very low bandwidth mode of operation on the Link (about 10 Mbps), so it is critical that there is enough time between scheduled synchronous timing packets to perform any LP transactions.

The following latencies need to be accounted for if a LP transaction is going to be performed:

- The available time between Sync packets in the Vertical blanking region
- HS to LP and LP back to HS Link transition latencies (HS to HS latency)
- Bus Turn-Around (BTA) latency, if doing a BTA
- LP transmission

The below diagram illustrates the durations available for LP communication within a Vertical blank line time.



The amount of time available for the LP transactions within the V. blanking region is dependent on whether the transcoder is in the Sync Pulse of Event mode.

Sync Mode	BLLP Duration
Pulse	H. Total - (H. Sync End - H. Sync Start)
Event	H. Total

Since the Horizontal timings are defined in terms of pixels, the BLLP Duration needs to be converted to the Byte clock domain using the following equation:

Number of Byte Clocks = Ceiling((H. Size * Bytes per Pixel) / Operating Width)

The HS to HS transition latencies are given in the following table:

CLK Lane in LP?	HS2HS Transition Latency
Yes	(N * 17) + 12
No	(N * 7.5) + 4

Where N is the number of Byte clocks per Escape clock

N = ceiling(f_{Link} (MHz) / 160)

Note that the above Link transition latencies assumes the default HW maintained timing parameters. If any of the timing parameters are being overridden by SW, than that needs to be accounted for.

So, given the above, the amount of time available for the actual LP transmissions is given as the following:

Direction of LP Transaction	Allowed Duration
Tx	BLLP Duration - HS2HS Latency
Rx	BLLP Duration - HS2HS Latency - Turnaround Timeout

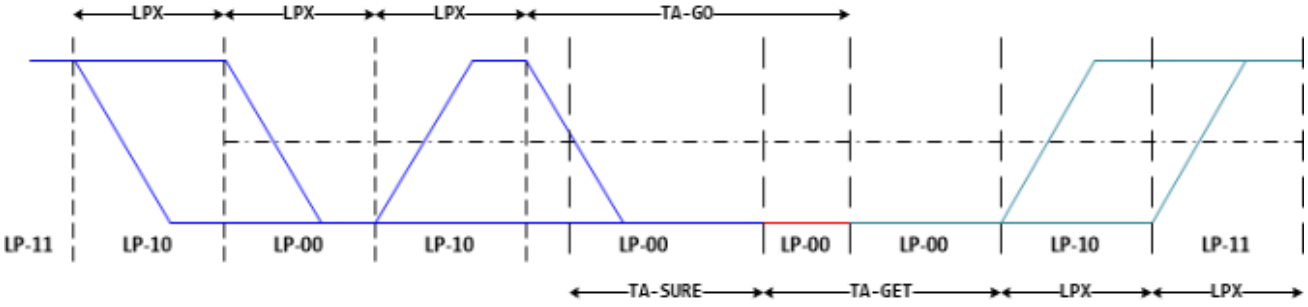
Some things to note on the above durations:

1. For the receive direction, the maximum amount of time given to perform a BTA is defined by the Turnaround Timeout (DSI_TA_TO). This timeout is in Escape clocks, so it will need to be multiplied by N
2. For the receive direction, Software should program the LP RX Timer Timeout (DSI_LRX_H_TO) to the allowed Rx duration.
3. For the receive direction, Software should program the Set Maximum Return Packet Size to account for the allowed Rx duration. Note that the value programmed should take into account the overhead of the Escape Mode entry, exit, packet header, and payload CRC.

Programming DSI_TA_TO and DSI_LRX_H_TO

The TA_TO and LRX_H_TO timers specify how long the DSI controller (i.e. the Host) will allow the panel to own the bus when there is a bus turn-around in progress.

For the turnaround time (DSI_TA_TO), the sequence to turn the Data Lane around is given below:



The table below shows the latency of a bus turn-around.

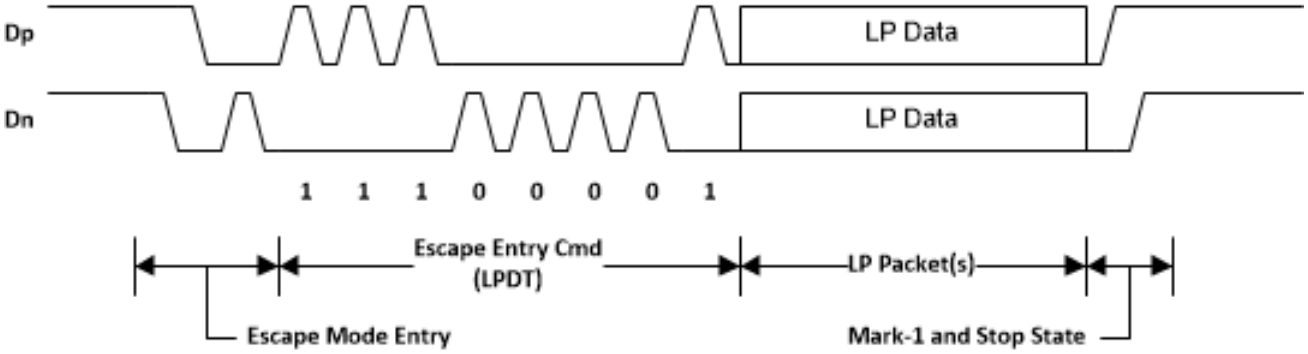
Sequence Step	HW Maintained (1)	SW Override (1)
LP10	1	1
LP00	1	1
LP10	1	1
V_{OL} (2)	1	1
LP00 (3)	6	TA-SURE + TA-GET

Sequence Step	HW Maintained (1)	SW Override (1)
LP10	1	1
LP11	1	1
Guardband (4)	2	2
TOTAL:	**14**	**8 + TA-SURE + TA-GET**

Notes:

1. The latencies are in terms of Escape clocks (i.e. T_{LPX})
2. From when the Physical layer starts driving the TA-SURE step of the sequence (i.e. LP10 to LP-00), there is a short latency for the 1->0 transition to pass the V_{OL} threshold. This latency is less than one T_{LPX}, but since the granularity of the timeout timer is at the Escape clock granularity, this step is rounded up to one Escape clock.
3. TA-SURE, and TA-GET timing parameters are maintained by the Host and can, therefore, be overridden by Software. HW maintains a TA-SURE of 1 T_{LPX} and a TA-GET of 5 T_{LPX}
4. The guardband is to account for any clock crossings

For the amount of time that the panel should be allowed to own the link (DSI_LRX_H_TO), the timeout value is dependent on the maximum amount of data that the panel could have to send back to the Host. The worst case amount of data the panel can send back to the Host is a READ return followed by an Acknowledge and Error packet.



Sequence Step	Duration (1,2)
Escape Mode Entry	5
Escape Entry Cmd	16
LP Packets	READ Hdr: 64 READ Pyld: 512 (3) READ Pyld CRC: 32

Sequence Step	Duration [1,2]
	Ack & Error Hdr: 64 [4]
Mark-1 and Stop State	2
Bus Turn-Around	14
Total:	**709**

Notes:

1. When in the Escape Control domain, it takes two Escape clocks (T_{LPX}) to transmit a given bit (e.g. the Escape Entry Command is 8 bits, so it takes 16 T_{LPX} to transmit the command)
2. This analysis is assuming the panel is not stalling
3. The Host can accept up to 32 bytes of READ payload data from the panel (i.e. the Set Maximum Return Packet Size can be set up to 32). Software can control how much READ data the panel sends for each BTA.
4. This analysis is assuming the panel sends the Acknowledge and Error packet immediately after the READ packet.

Transcoder Control

Control
TRANS_CONF
TRANS_STEREO3D_CTL

Transcoder LRR

LRR (Low refresh rate) is mainly about dynamically reducing panel refresh rate to lowest possible refresh rate or to media multiple refresh rate (e.g. 48Hz) for idle and media playback scenarios. LRR provides predictable VBI unlike flip based refresh rate. LRR feature relies on software programmed Vtotal functionality and can be enabled on VRR capable panels.

Entry Sequence

1. If VRR is enabled, driver disables VRR.
2. Driver updates Vtotal and Vblank-end to any refresh rate supported by the panel.

Exit Sequence

1. Driver updates Vtotal and Vblank-end to nominal refresh rate.

Here is an example scenario with idle and LRR.

1. Configure eDP/DP at 60 Hz.

2. LRR idle entry: Update Vtotal and Vblank-end for 40 Hz
3. LRR idle exit: Update Vtotal and Vblank-end for 60 Hz
4. Enalbe VRR and program flips
5. Disable VRR
6. LRR media playback entry: Program flip and then update Vtotal and Vblank-end for 48 Hz
7. LRR media playback exit: Update Vtotal and Vblank-end for 60 Hz

LRR Restrictions

- After push, software must wait for push done before starting another push.
- Global Double Buffer Disable functionality is not supported with LRR.
- No asynchronous flips are allowed when LRR is enabled.
- Interlaced mode, DRRS, Stereo 3D, and PSR2 are incompatible with LRR.
- Since panels may have a restriction on the maximum change in refresh rate between two consecutive frames, disabling LRR (TRANS_VRR_CTL[31]==0) does not immediately bring the current refresh rate to the nominal refresh rate.
- When using the transcoder port sync mode, LRR must use Pipeline Full Override Programmed Pipeline Full Line Count setting in TRANS_VRR_CTL.
- PSR is incompatible with LRR.

Transcoder Timing

Transcoder
TRANS_HTOTAL
TRANS_HBLANK
TRANS_HSYNC
TRANS_VTOTAL
TRANS_VBLANK
TRANS_VSYNC
TRANS_SPACE
TRANS_VSYNCSHIFT
TRANS_MULT

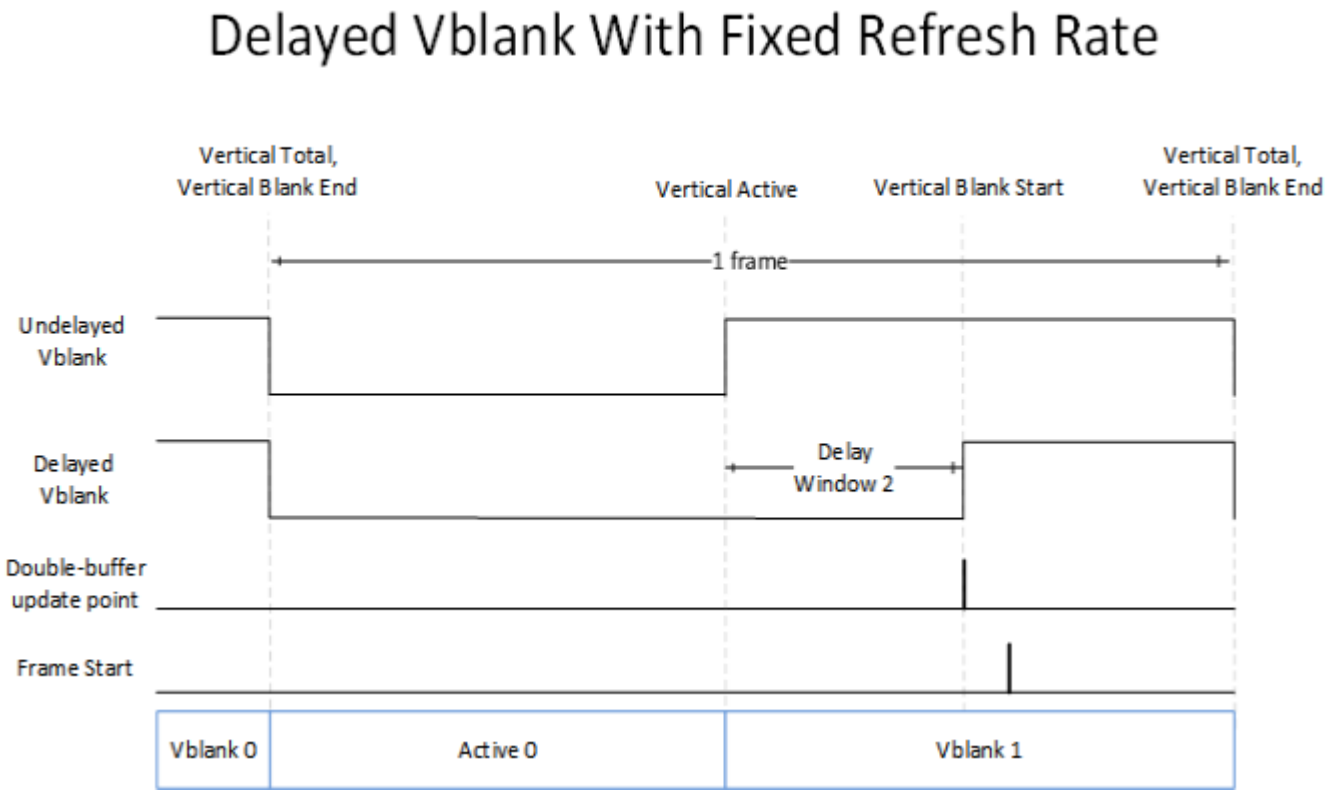
The transcoder timing generators create two versions of vertical blank (vblank) that are sent to the display pipes. The undelayed vblank asserts at the end of vertical active (TRANS_VTOTAL Vertical Active). The delayed vblank asserts at the vertical blank start (TRANS_VBLANK Vertical Blank Start) and must be programmed greater than or equal to the end of vertical active. Both de-assert at the end of vblank (TRANS_VBLANK Vertical Blank End), which must be programmed to match the vertical total (TRANS_VTOTAL Vertical Total).

The rising edge of the delayed vblank is the double-buffer register update point. The frame start signal asserts after that point, then pixel processing begins for the next frame.

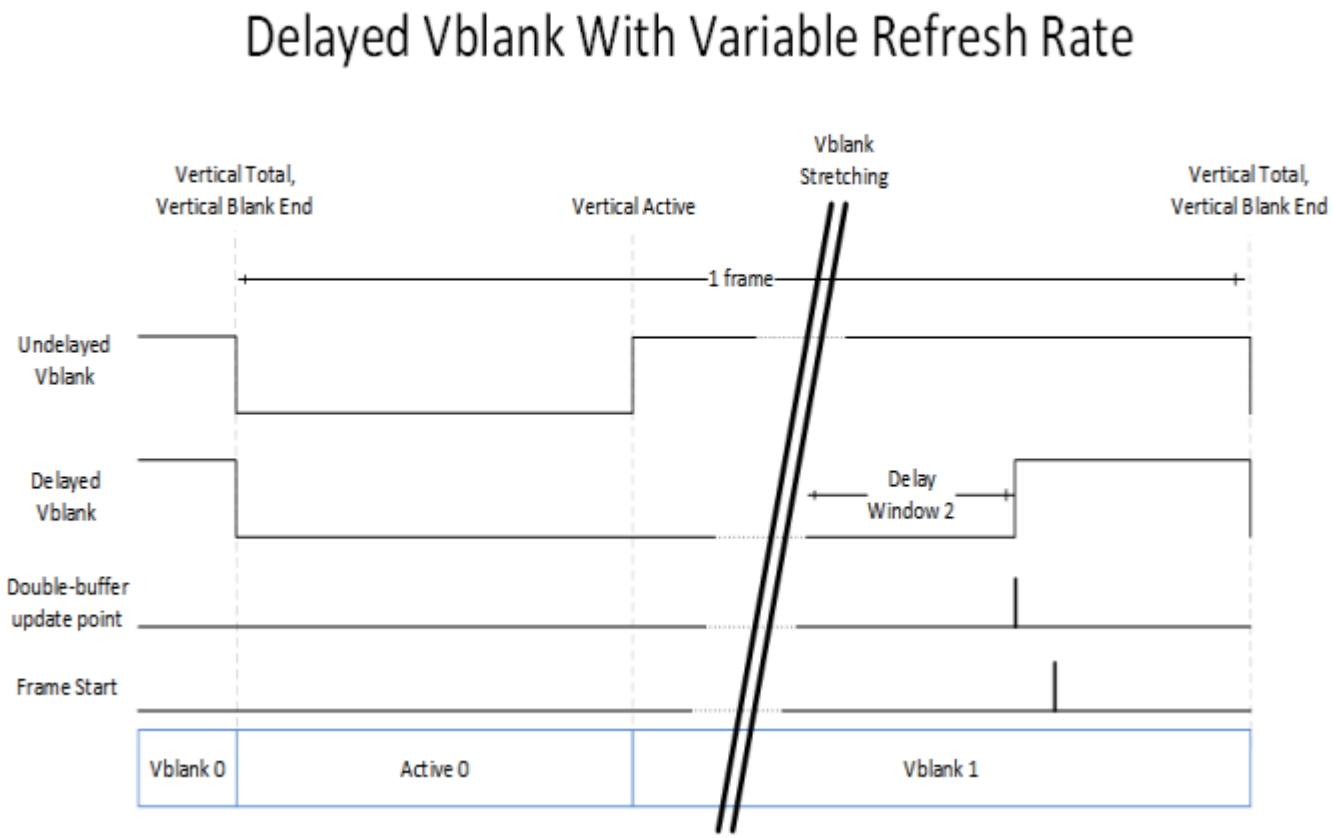
TRANS_VBLANK Vertical Blank Start can be programmed greater than TRANS_VTOTAL Vertical Active to create a window between start of undelayed vblank and delayed vblank where pixels are not being processed (called window 2) and programming can safely update double-buffered and non-double-buffered registers.

Window 2 size = TRANS_VBLANK Vertical Blank Start - TRANS_VTOTAL Vertical Active

Window 2 is typically only configured to be greater than zero when DSB will be used to program display registers. Without DSB, driver MMIO programming usually is too slow to fit in window 2, and instead must update only the double-buffered registers and use capabilities like the double buffer update disable to ensure atomic updates, and then there is no need to delay the vblank. See the DSB Engine Programming for window 2 size requirements.



When variable refresh rate is used, the vblank stretches while waiting for the indication to complete this vblank and start the next frame. The stretching happens before window 2.



Transcoder MN Values

There is one instance of these registers per each transcoder.

For dynamic switching between multiple refresh rates, M/N values may be reprogrammed on the fly. The link N should be programmed last to trigger the update of all the data and link M and N registers and then the new M/N values will be used in the next frame that is output.

DATAM

DATAN

LINKM

LINKN

Clocks:

ls_clk is the link symbol clock. i.e. 270 MHz for HBR.

strm_clk is the stream clock, which is the video pixel rate or dot clock.

cdclk is the core display clock.

The link only operates in Synchronous Clock mode. The link clock and stream clock are synchronous and the link M and N values stay constant for a given pixel rate.

Calculation of TU:

TU is the Transfer Unit used in SST.

TU size = 64 (recommended)

Calculation of Data M, and Data N:

Active/TU Size = Payload/Capacity = Data M/N

Note that for 4:2:0 format the number of bytes per pixel will be half the number of bytes of RGB 4:4:4 pixel.

Recommendation: In data M/N calculation, M should be rounded up and N should be rounded down.

Context:	Low Bandwidth SST over High BW link
Active/TU size = Data M/N Select link rate such that there is at least 1 active symbol in every TU for any given dot clock. An example where this check fails is 720p with YUV 4:2:0 pixel format over HBR3 channel: Active/64 = (27 * 1.5) / (810 * 4) results in Active < 1.	

Compression Ratio (CR) = DisplayPort Compression enabled ? min(ratio1,ratio2) : 1

- ratio1 = Compressor BW / Link BW = (cdclk * bytes per pixel) / (ls_clk * number of lanes)
- ratio2 = (Horizontal active in pixels * bytes per pixel / 4) / ((Horizontal active in pixels * bytes per pixel / 8) +2)

Data M/N = (strm_clk * bytes per pixel) / (CR * ls_clk * number of lanes)

The data M/N should be calculated as below for the eDP cases with VESA DSC.

First compute the compression ratio based on the DSC PPS parameters as follows.

without FEC:

Compression Ratio (CR) = DSC input bits per pixel / DSC output bits per pixel

Examples:

RGB444: Compression Ratio (CR) = bits_per_component *3 / bits_per_pixel

If eDP CoG with VESA compression

Data M/N = ($strm\_clk_{CoG}$ * bytes per pixel) / (CR * ls_clk * number of lanes per segment)

else if eDP with VESA compression (no CoG)

Data M/N = (strm_clk * bytes per pixel) / (CR * ls_clk * number of lanes)

Note1: Data M/N remains unchanged between CoG and non-CoG because the reduction in the number of lanes is compensated by the reduction in stream clock.

Note2: For the CoG case above, the actual stream clock on pipe side = ($strm\_clk_{CoG}$ * number of segments).

Note3: $strm\_clk_{CoG}$ is calculated considering a single segment

with FEC:

Compression Ratio (CR) = DSC input bits per pixel / DSC output bits per pixel

Examples:

RGB444: Compression Ratio (CR) = bits_per_component *3 / bits_per_pixel

If eDP CoG with VESA compression

Data M/N = ((strm_clk$_{CoG}$ * bytes per pixel) / (ls_clk * number of lanes per segment)) * 1/(0.972261 * CR)

else if eDP with VESA compression (no CoG)

Data M/N = ((strm_clk * bytes per pixel) / (ls_clk * number of lanes)) * 1/(0.972261 * CR)

Note1: Data M/N remains unchanged between CoG and non-CoG because the reduction in the number of lanes is compensated by the reduction in stream clock.

Note2: For the CoG case above, the actual stream clock on pipe side = (strm_clk$_{CoG}$ * number of segments).

Note3: strm_clk$_{CoG}$ is calculated considering a single segment

The data M/N should be calculated as below for the case FEC is enabled over the link in order to account for the 2.4% overhead.

Data M/N = ((strm_clk * bytes per pixel)/(ls_clk * number_of_lanes)) * 1/(0.972261)

If compression is also enabled, then the following calculation should be used.

Data M/N = ((strm_clk * bytes per pixel)/(ls_clk * number_of_lanes)) * 1/(0.972261*CR)

Calculation of Link M and Link N:

Link M/N = strm_clk / ls_clk - for non-CoG use cases

Link M/N = strm_clk$_{CoG}$ / ls_clk - for CoG use cases

Recommendation: In Link M/N calculation, M should be rounded up and N should be rounded down.

Restriction on clocks and number of lanes:

- Number of lanes >= INT(strm_clk * bytes per pixel / ls_clk)

Restrictions on the Virtual Channel (VC) payload size in DisplayPort MST mode

- In a x1 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 4.
- In a x2 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 2.
- In a x4 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 1.

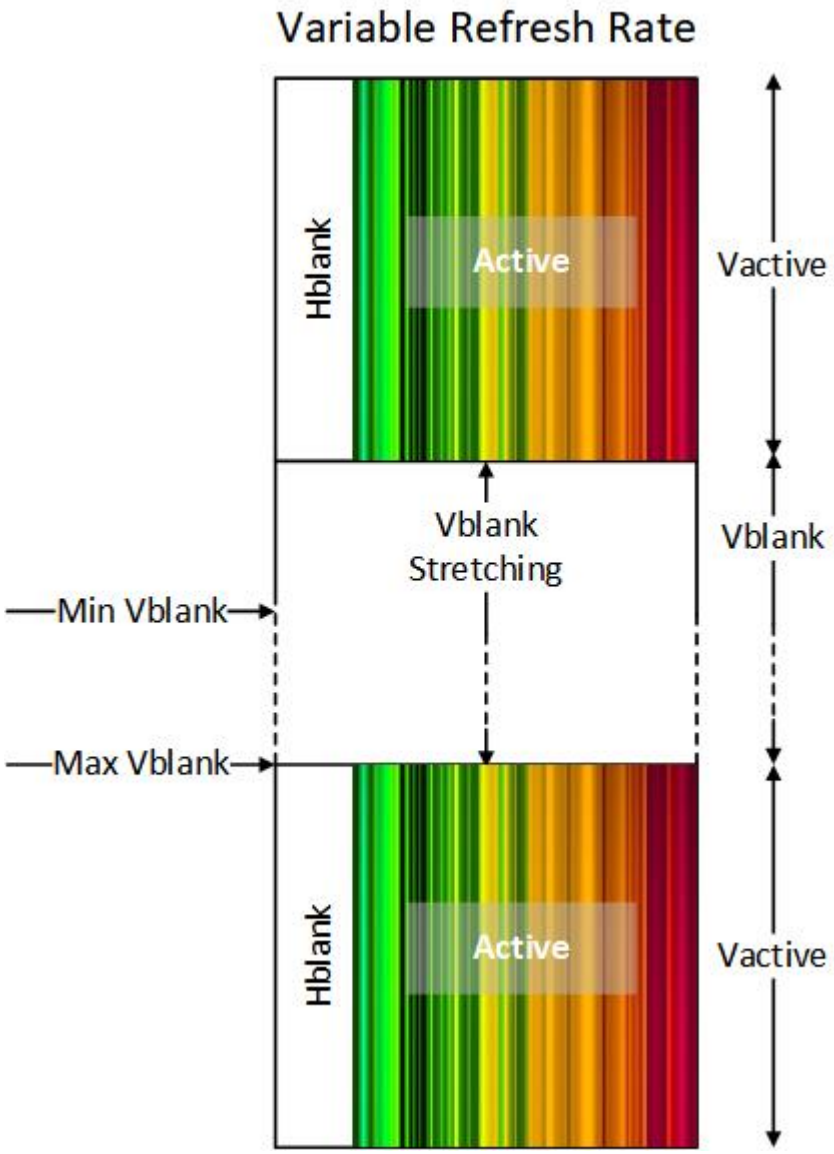
VRR Overview

In the adaptive sync mode (a.k.a. VRR or Variable Refresh Rate), the display engine adapts itself to render speed by adjusting its refresh rate dynamically. Adaptive sync mode is supported both on eDP and DP. The dot clock is set to support the peak desired refresh rate for a given resolution and link clock. A minimum and maximum vertical blank (vblank) period is specified and the display hardware stretches or shrinks the actual vblank period based on the required refresh rate.



VRR Details

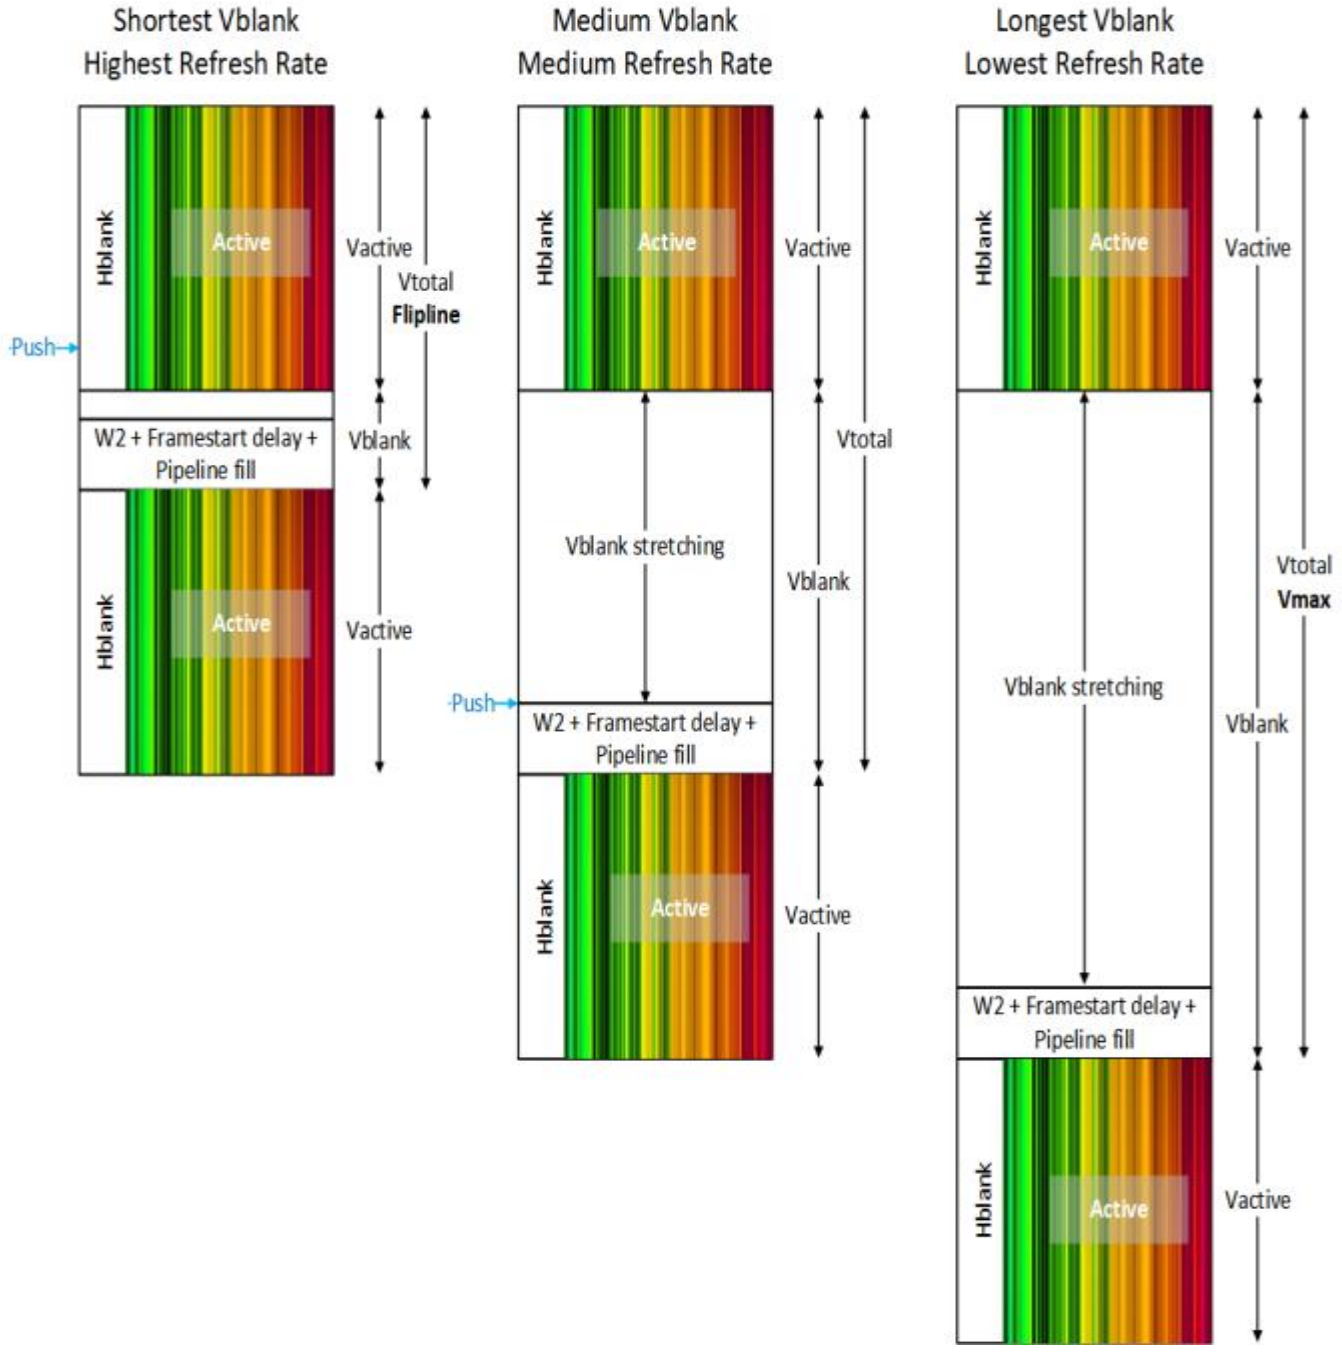
VRR stretches the beginning of vblank until the vblank needs to be terminated, then delay window 2 (W2) happens, double buffer registers are updated (sync flips complete), framestart is triggered (after a delay), the display pipeline fills, and vblank ends.

The vblank period is constrained by the registers specifying vertical total (Vtotal) lines maxium (Vmax) and minimum (Vmin). The Vtotal contains the Vblank and vertical active (Vactive) region of each display frame. The minimum Vblank must at a minimum contain the framestart delay and pipeline fill.

When there is a frame update (flip or other update), software triggers the termination of vblank by setting the transcoder Send Push bit (push bit). The start of termination may be immediate, or delayed, depending on flip line and max shift. Hardware clears the push bit when the vblank termination begins. The vblank termination is the flip decision boundary, or latest time a push will be serviced. If a push is set after flip decision boundary, it will be held until the next vblank and serviced there.

Flip Line provides a frame by frame programmable limit on the minimum Vtotal. The flip line is programmed before the push. Hardware calculates the flip line decision boundary = flip line value - pipeline fill - framestart delay. If push happened before that boundary point, the vblank termination starts at that boundary point. If push happens after that boundary point, the vblank termination starts immediately.

When software does not trigger termination, the vblank automatically terminates when the programmed vertical max (Vmax) will be reached. Hardware calculates the Vmax decision boundary = Vmax - pipeline fill - framestart delay, and starts termination at that boundary point.

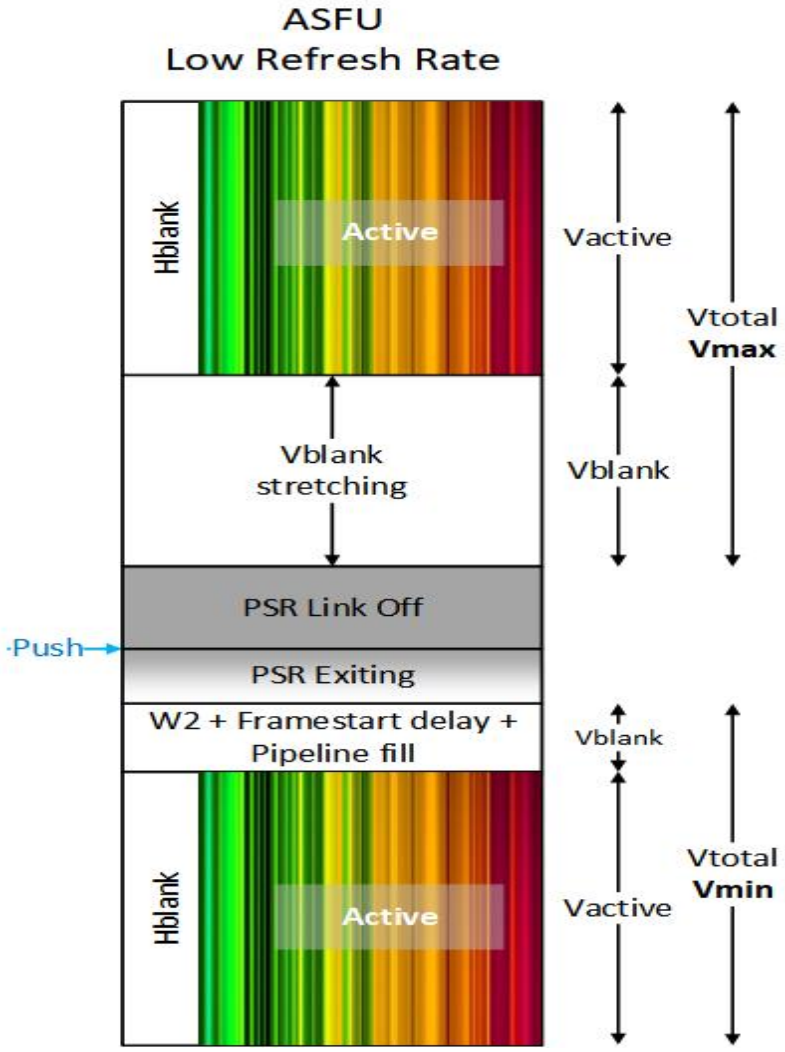


Double-Buffer Behavior

The push mode causes VRR to affect all pipe and plane double-buffered registers. As the vblank sent to the panel (timing generator vblank or undelayed vblank) stretches it delays the assertion of vblank sent to the pipe (delayed vblank), which is used as the double-buffer update for all of the pipe and planes. When VRR begins to terminate the vblank, delay window 2 (W2) happens, then the delayed vblank asserts, triggering the double buffer update before the framestart and pipeline fill. As a result, double-buffer registers will update after the push is set, or in a non-ASFU case, when vmax decision boundary is reached.

ASFU

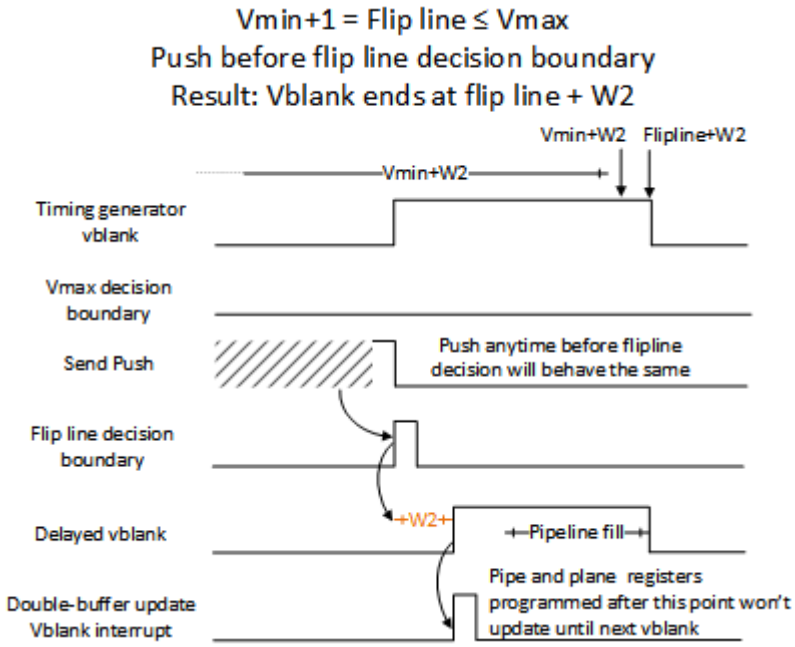
Adaptive Sync Frame Update (ASFU) changes the VRR behavior when max vertical is reached so that it enters PSR instead of terminating vblank and starting another frame. A later push then causes PSR exit with minimum vblank (flip line value ignored at PSR exit). The VRR behavior with push before Vmax decision boundary is unchanged by ASFU.



VRR Scenarios

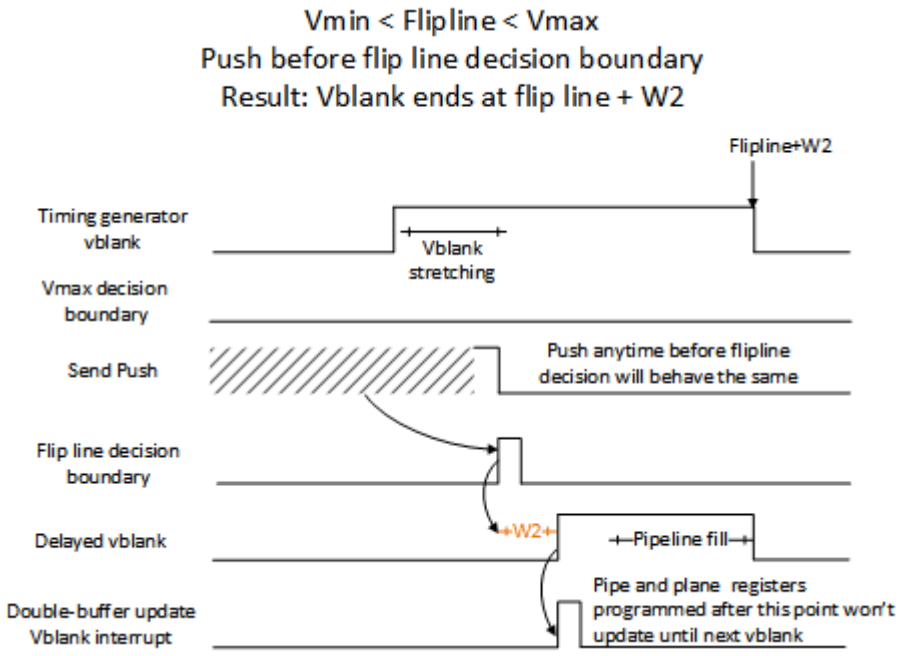
Minimum vblank

If push happens before flip line decision boundary and flip line value is Vmin+1, the vblank is minimized and the plane and pipe double-buffer registers update at the start of timing generator vblank.



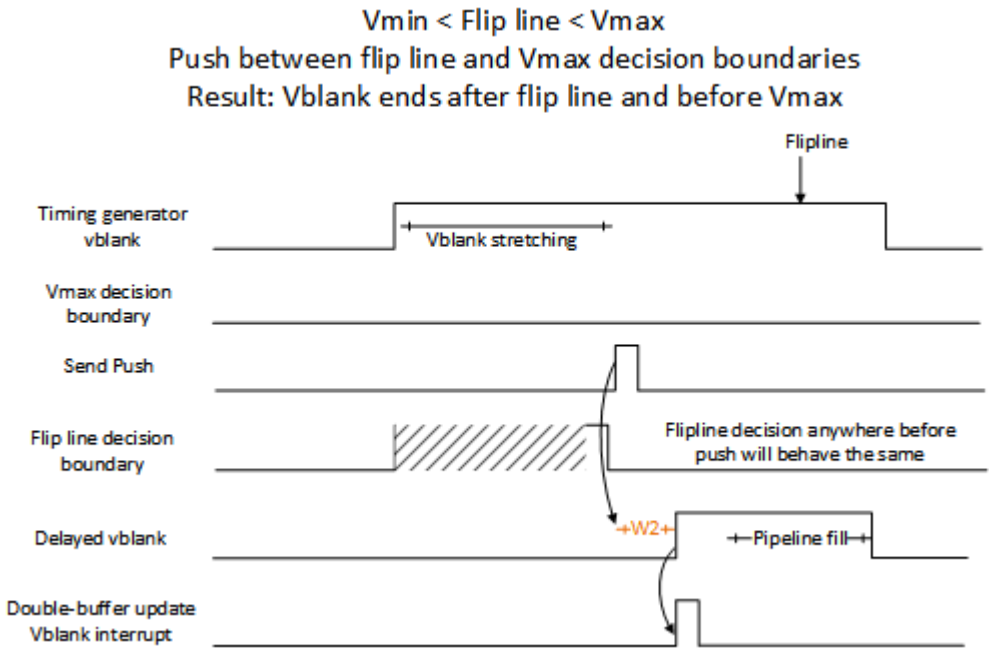
Medium vblank terminated at flip line

If push happens before flip line decision boundary and flip line value is greater than Vmin and less than or equal to Vmax, the vblank will stretch and the plane and pipe double-buffer registers update at the flip line decision boundary.



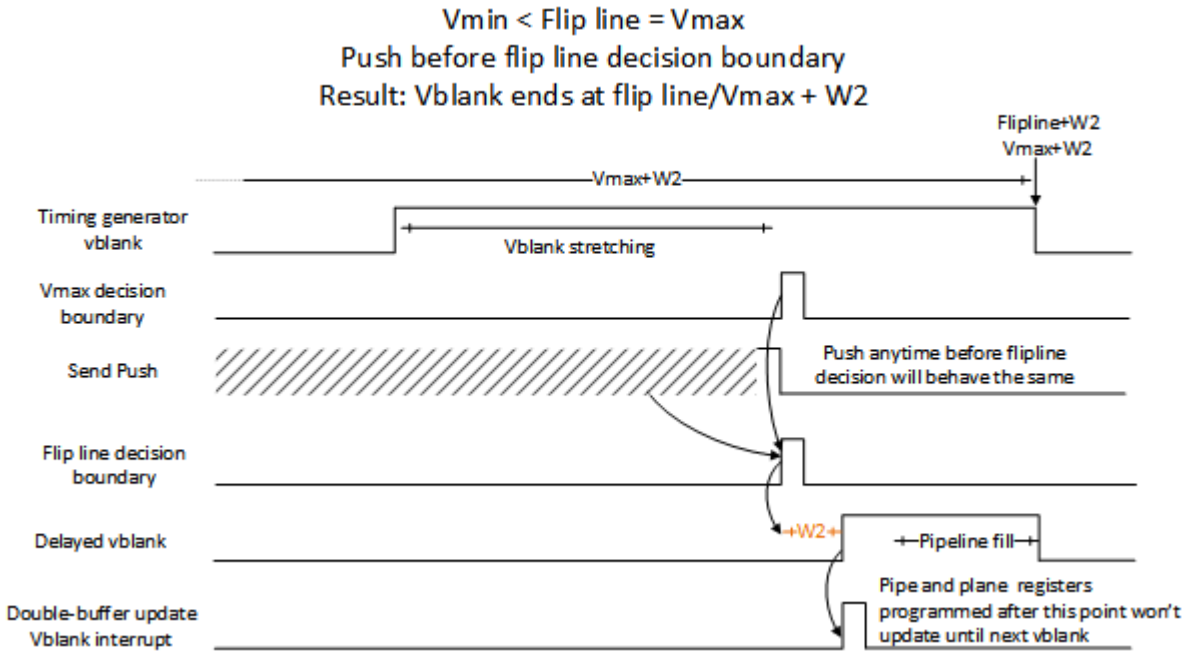
Medium vblank terminated at push

If push happens after flip line decision boundary and before Vmax decision boundary, the vblank will stretch and the plane and pipe double-buffer registers update at the push.



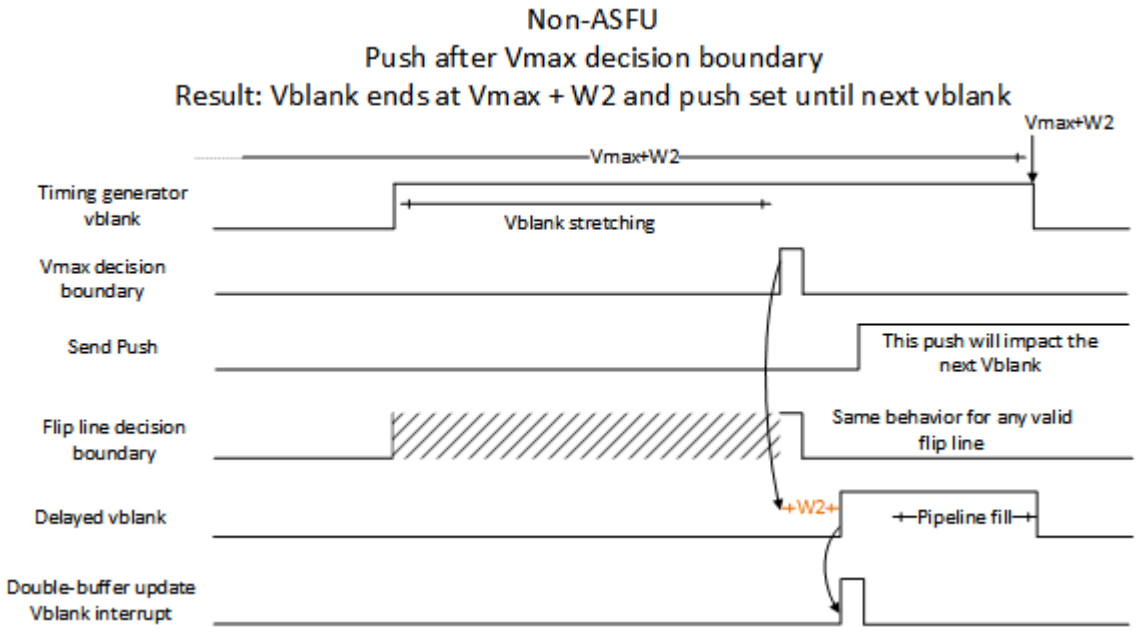
Maximum vblank terminated at flip line

If push happens before flip line decision boundary and flip line value is equal to Vmax, the vblank will stretch to the max and the plane and pipe double-buffer registers update at the Vmax and flip line decision boundary.



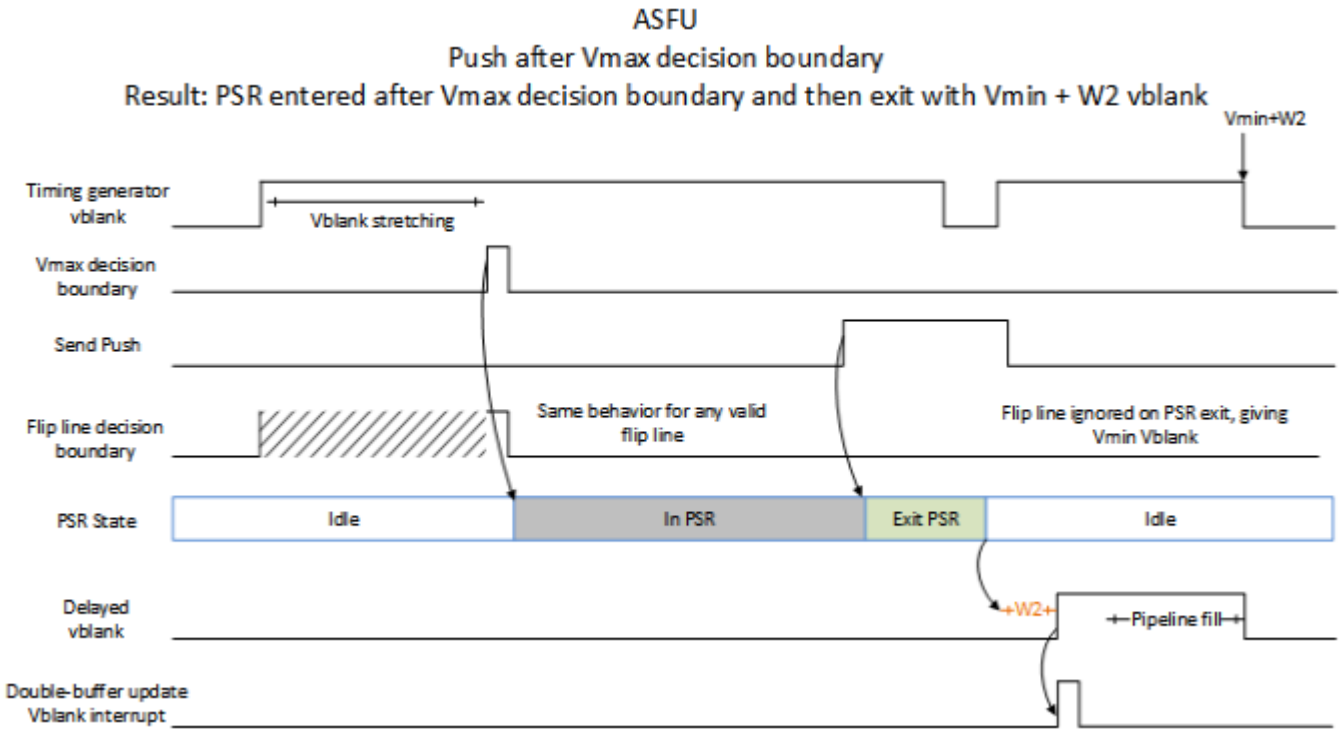
Maximum vblank terminated at Vmax

If PSR is disabled and push happens after Vmax decision boundary, the vblank will stretch and the plane and pipe double-buffer registers update at the Vmax decision boundary.



Maximum vblank enters PSR

If PSR is enabled (for ASFU) and push happens after Vmax decision boundary, the vblank will stretch and enter PSR after the Vmax decision boundary. The push then causes PSR exit with minimum vblank (flip line ignored at PSR exit) and the plane and pipe double-buffer registers update at the start of vblank.



Programming Sequence

1. Enable VRR
    - This can be done after mode set (called VRR Enable Sequence 1), or during mode set in the step that configures transcoder timings and other pipe and transcoder settings so that VRR is enabled from the first frame (called VRR Enable Sequence 2).
    1. Configure VRR timing and control registers
        - TRANS_VRR_CTL Pipeline Full Override must be set and the FrameStart to Pipeline Full LineCount programmed.
        - TRANS_PUSH Push Enable must be set.
        - If max shift, TRANS_VRR_CTL Ignore Max Shift and Flip Line Enable must be clear, else Ignore Max Shift and Flip Line Enable must be set.
    2. If adaptive sync SDP use case
        - Program TRANS_VRR_VSYNC
        - Set "Adaptive Sync SDP Enable" in VIDEO_DIP_CTL register
    3. Set TRANS_VRR_CTL VRR Enable
    4. If ASFU, enable PSR - See Panel Self Refresh chapter

2. Screen updates, repeat as needed for each update
    1. Program the double-buffer registers that need updating
        - There will be a double-buffer update at Vmax decision boundary if ASFU is not used, so care must be taken to ensure multiple resource programming does not straddle the double-buffer update point and cause non-atomic updates.
            - Options
                - Use ASFU so that PSR is entered at Vmax.
                - Align programming to happen before the Vmax decision boundary.
                - Use double buffer disable/stall mechanisms to stall double buffering until all programming is complete.
    2. If not max shift, program Flip Line value in TRANS_VRR_FLIPLINE (this can be programmed multiple times before the next step).
        - Flip Line value cannot be changed between when the push is initiated and the push is done.
    3. Set TRANS_PUSH Send Push
    4. Hardware will clear the Send Push when the double buffer update happens
    5. Poll for TRANS_PUSH Send Push cleared
3. Disable VRR
    1. If ASFU, disable PSR - See Panel Self Refresh chapter
    2. Clear TRANS_VRR_CTL VRR Enable
    3. Stop setting push
        - Push is not needed when VRR is disabling because frames will terminate automatically.
        - Setting push after VRR is disabled will cause the push to be held until later VRR enabling. That is not validated and not supported.
    4. Poll for VRR live status indicating VRR has disabled.
        - VRR live status takes one frame to change after VRR mode is disabled.
        - Depending on VMAXSHIFT, the vblank length may keep changing for several frames after VRR mode is disabled, which is interrupted by disabling the transcoder or re-enabling VRR.

- VRR double buffer update interrupt will remain active until VRR live status is de-asserted.
    1. TRANS_PUSH Push Enable can be cleared at this point or later
    2. VRR can be re-enabled by returning to step 1.
    3. If port will be disabled, continue to mode set disable sequence.
        - Hardware may be capable of transcoder disable with VRR enabled, but that is not validated and not supported.

VRR with Port Sync Mode

Port sync has multiple transcoders running synced together. The primary transcoder will send sync signals to the secondary transcoders.

Program the VRR registers the same on both transcoders when enabling VRR.

> VRR_CTL VRR Enable and TRANS_PUSH Push Enable must be set on primary and secondary transcoders. The other registers may not all be necessary for the secondary transcoders, but programming them differently is not validated and not supported.

When sending screen updates, only the primary transcoder VRR needs to be updated. Only set push on the primary transcoder and only update the flip line value on the primary transcoder.

Starting VRR from Nominal Refresh Rate

1. Driver determines the panel timings and the highest, lowest, and nominal refresh rates to support
2. Driver does mode set to the highest pixel rate and highest refresh rate timings (should be close to CVT1.2 RB), except it extends the vertical total so that the resulting refresh rate is nominal.
3. Driver enables VRR with Vmax for the lowest refresh rate and Vmin for the highest refresh rate. Vmin = the vertical total from the mode set before extending to nominal refresh rate.
4. Hardware will vary refresh rate between the Vmax and Vmin based on the timing of pushes.
5. Hardware will also vary refresh rate between the Vmax and Vmin based on the VMAXSHIFT.

1. When VRR is disabled the refresh rate will return to Vtotal (nominal).

- Steps 2 and 3 may be separated (VRR Enable Sequence 1) or combined so that VRR is enabled during the mode set (VRR Enable Sequence 2).
- The pixel rate and horizontal timings are programmed to match the highest refresh rate and do not change.

Starting VRR from Maximum Refresh Rate

1. Driver determines the panel timings and the highest, lowest, and nominal refresh rates to support.
2. Driver does mode set to the highest pixel rate and highest refresh rate timings (should be close to CVT1.2 RB).
3. Driver enables VRR with Vmax for the lowest refresh rate and Vmin for the highest refresh rate. Vmin = vertical total from the mode set.
4. Hardware will vary refresh rate between the Vmax and Vmin based on the timing of pushes and VMAXSHIFT.

1. When VRR is disabled the refresh rate will return to Vtotal (same as Vmin).
2. It will take several frames to return, depending on VMAXSHIFT.

- Steps 2 and 3 may be separated (VRR Enable Sequence 1) or combined so that VRR is enabled during the mode set (VRR Enable Sequence 2).

- The pixel rate and horizontal timings are programmed to match the highest refresh rate and do not change.

DPCD

Video timing information in the DP MSA (main stream attribute packet) data is designed for video modes where the parameters are static. For modes such as VRR that dynamically change the video timing, the main stream attribute fields cannot be used. Therefore, panel DPCD registers need to be appropriately programmed for VRR use cases.

VRR Restrictions
• Interlaced mode, DRRS, Stereo 3D, and PSR2 are incompatible with VRR.
• Vmin = window 2 + Vactive + framestart delay + pipeline fill
• Vmax must be greater than Vmin. Vmin < Vmax
• After push, software must wait for flip done before starting another push.
• PSR is supported with VRR for the Adaptive Sync Frame Update (ASFU). • ASFU is mutually exclusive with max shift. • Flip Line must always be enabled when VRR is enabled, except if max shift is enabled. • Flip Line is mutually exclusive with max shift. • Flip Line value cannot be changed between when the push is initiated and the push is done. • Flip Line value must be less than or equal to Vmax. Flip Line <= Vmax • Flip Line value must be greater than Vmin. Vmin < Flip Line.   • Flip Line value equal to Vmin is not supported and causes vblank terminated by flip line to have an extra line.

Adjusting for Delayed Vblank Window 2

If vblank is delayed to create window 2 (see Transcoder Timings section), then VRR programming needs to be adjusted to account for window 2. Hardware does not calculate window 2 in the decision boundaries. Window 2 is inserted before the delayed vblank asserts, and is preserved when vblank stretches for VRR, so it has the impact of pushing out vblank by window 2 size. The window 2 size then needs to be subtracted when programming the VRR vblank affecting registers to get the desired result.

VRR Vmin = Desired Vmin - window 2 size

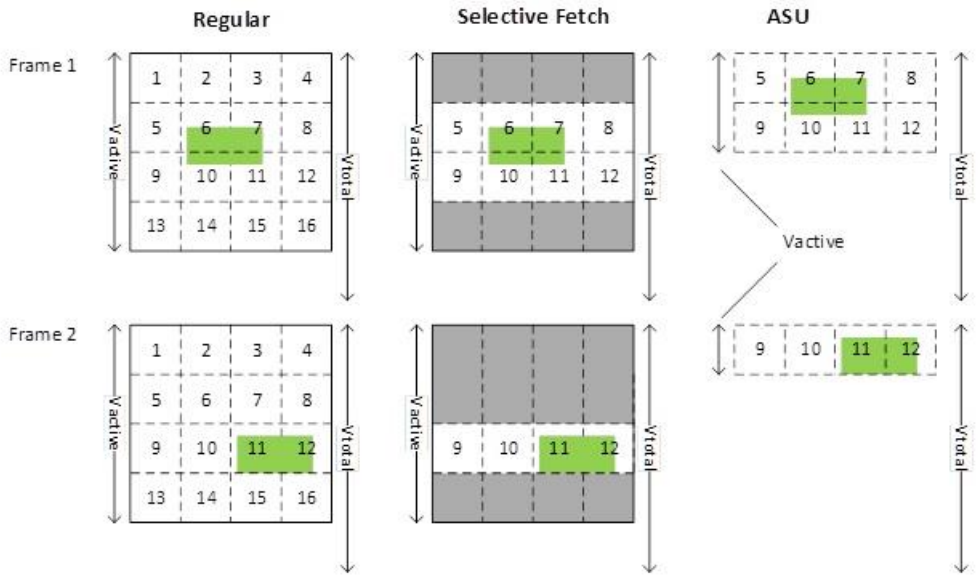
VRR Vmax = Desired Vmax - window 2 size

Flipline = Desired flipline - window 2 size

FrameStart to Pipeline Full LineCount must be calculated using the adjusted VRR Vmin.

Transcoder Asynchronous Selective Update

This feature extends ASFU to partial frame updates and adds the capability of updating one region of the display using the ASFU framework. Only one update region per frame is supported and the capability is only supported with manual tracking mode/selective fetch. A Metadata packet will transfer the co-ordinates of the update region as a proprietary secondary data packet, prior to sending the active data for the frame. All the framework available with ASFU will continue to apply to ASU. If compression is enabled, ASU mandates that the PPS sent to the panel be fixed and it should not change on the fly. Hence, DSS control registers once configured, should not be modified for partial updates. ASU does not support CoG use cases.



- Dashed lines represent DSC slice
- Solid line represents full frame size
- Greyed out area not fetched
- Green are is updated region
- Pipe scaling would require fetch of extra slices around the updated region slices in order to have the data to fill scaler filters before entering the updated slices

ASU flows

1. Mode set enable.
2. PSR enable, wait for 1 Vblank.
3. If selective update, SW updates pipe source size, Vblank start, Vactive and slice_row per frame as per SU size.
4. Set TRANS_PUSH send PUSH.
5. SW to poll for push done bit.
6. HW will consume pipe source size and slice_row per frame @VBI and Vblank start and Vactive @Vtotal.
7. For subsequent selective updates, SW to poll on scanline interrupt, 1st line and go to step (3).

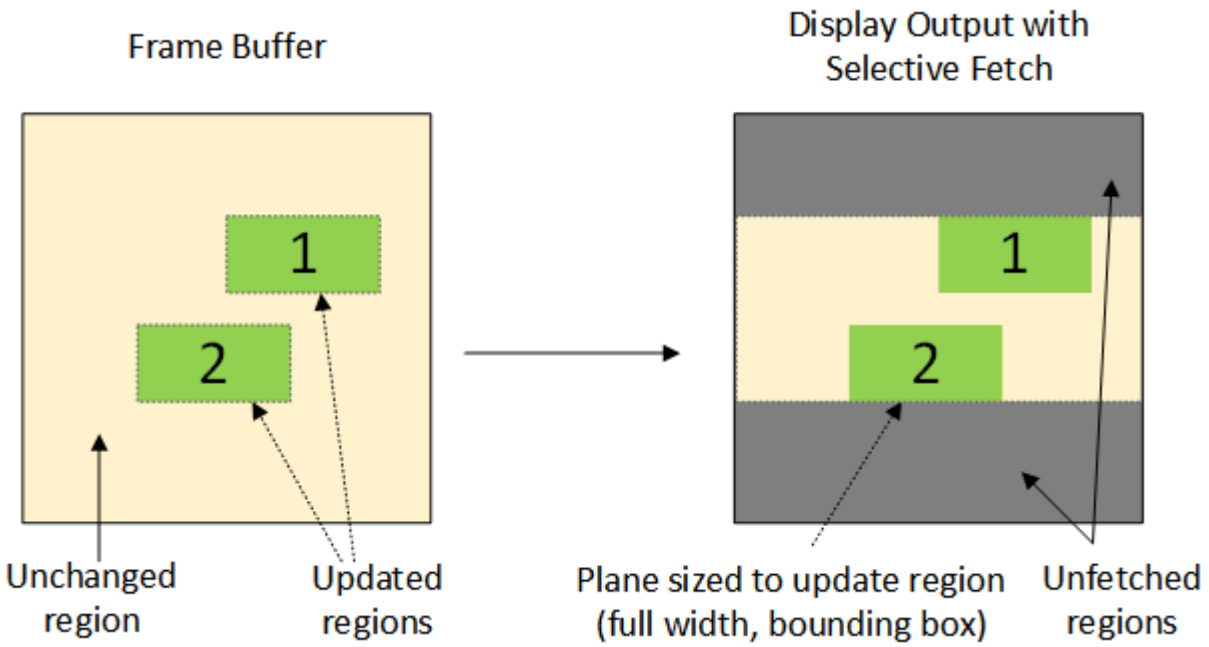
8. If PSR disable, wait for scanline interrupt, 1st line. Restore the original timing parameters.

The complete sequence is as follows.

1. Mode set enable
2. Push enable
3. DB Vactive enable
4. VRR enable
5. PSR enable, wait for 1 Vblank
6. Selective update
7. PUSH
8. Poll for PUSH done
9. SW to poll on scanline interrupt, 1st line for future selective updates
10. PSR disable
11. Restore original timing parameters
12. Program Vtotal to Vnominal.
13. VRR disable
14. DB Vactive disable
15. PUSH disable

Selective Fetch

Selective fetch is a power saving feature to reduce display engine use of memory bandwidth by only fetching (reading from memory) the updated regions of the frame buffer and sending those updated regions to a panel with a remote frame buffer and selective update capability. Software selects the amount of fetch by adjusting the size and position of the display planes to fit the updated regions in the frame, and configures panel selective update manual tracking to output that region to the panel. The result is that the bounding box around the updated regions is read from memory and delivered to the panel remote frame buffer and the other regions are not fetched and not sent to the panel, saving memory bandwidth, IO, and panel power.



Restrictions

• Supported with only full line width update region. Software must adjust the update region to full width. • Supported with only a single update region per frame. Software must create the bounding box around all regions. • Not supported with async flips. The plane size and position cannot be changed with async flips, so selective fetch cannot be used. Software must output a full frame for async flips. • Not supported with command streamer flips. Command streamer flips do not update the selective fetch plane registers without adding in extra LOAD_REGISTER_IMMEDIATE commands, which are too complicated. • Not supported with plane rotation. Software calculations to adjust update region coordinates are too complicated. • Not supported with plane or pipe scaling. Software calculations to account for extra lines of scaler filter input and adjusted scale factor and filter phase are too complicated. • Not fully supported with LACE/LDPST. The histogram accumulates across the frame and gives incorrect results when only part of the frame is updated. Software adjusts the histogram taking algorithm to get partial support.
• Not fully supported with DPST. The histogram accumulates across the frame and gives incorrect results when only part of the frame is updated. Software adjusts the histogram taking algorithm to get partial support.
• Supported with PSR2.
• Not supported with DSC.

Hardware

Hardware support of selective fetch is through the panel selective update feature with manual tracking, the planes and cursor selective fetch registers, and the full frame update triggers.

Software

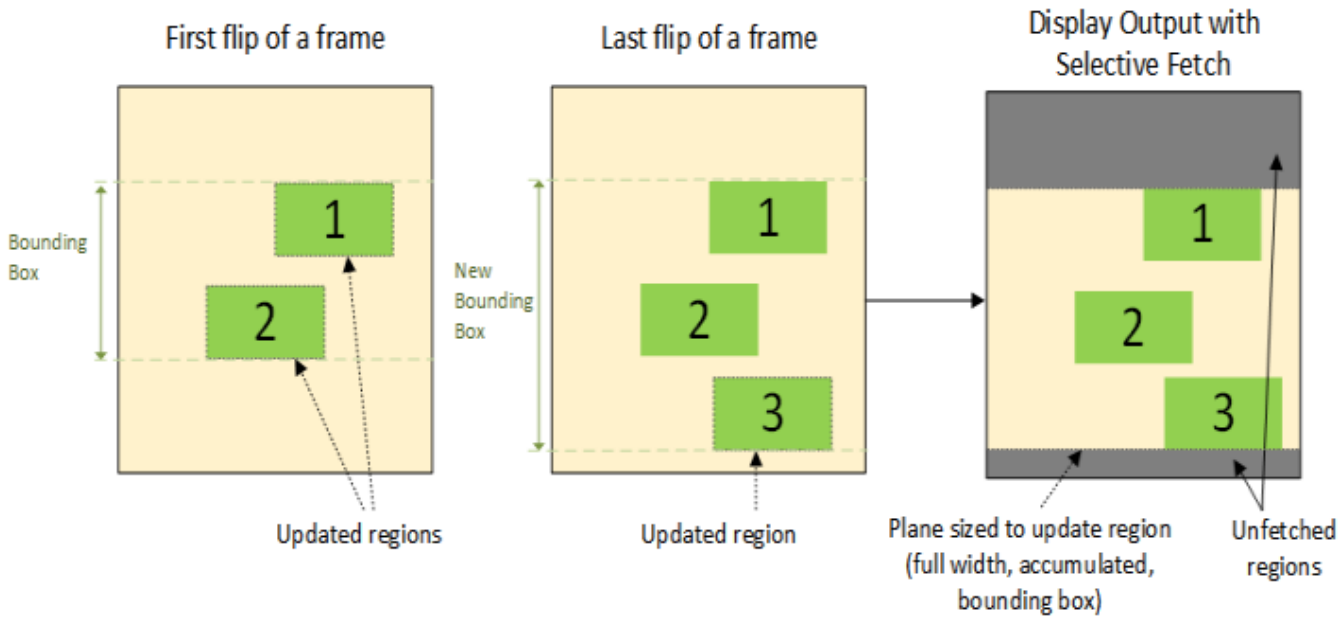
Software support of selective fetch

- Calculate the updated region
- Program the planes and cursor selective fetch registers to adjust the sizes, positions, and panning to fit the update region.
- Program the selective update manual tracking register to fit the update region.
- Program planes, cursor, and manual tracking together to atomically update.
- Trigger full frame updates when selective fetch cannot be used, such as when updating DPST image enhancement.

Update Region

Selective fetch requires software to know which areas of the screen are being updated. The update region coordinates are then used to adjust the planes and cursor to limit the fetch, and to notify the panel of which region has been selectively updated. The update region must be full width and just a single region per frame. Software must calculate the region as a bounding box to encompass all the updated sub-regions.

When there are multiple screen updates (flips) within a single frame, the update region can be different for each flip, but the final update region needs to be a bounding box that encompasses the update regions for all the flips in the frame. Hardware does not accumulate the update region across flips; it only uses the last programmed values. Software must either accumulate the update regions and program hardware with the accumulated result at each flip and reset accumulation at each frame, or trigger a full frame update when multiple flips happen within a single frame.



If there is a flip where the update region is unknown (e.g. application doesn't support this kind of tracking) or there is update that impacts the entire frame (e.g. pipe color correction programming), the update region is the full frame.

Update Region Alignment

Some features require the update region to be aligned to boundaries, then software needs to expand the update region to meet the alignment, increasing the amount of fetch.

For PSR2 selective update, the frame is divided into blocks of four scan lines each. The update region must be expanded so it aligns to the 4 line groups of transcoder vertical active.

Adjusting Plane and Cursor Size and Position

The selective fetch registers are an extra set of registers for each plane and cursor where software programs the adjusted size, position, offset (panning), and control (just the enable) to be used when doing a selective fetch. The regular (non SEL_FETCH) plane registers are used for full frame updates. Both sets must be updated with each flip, so that any frame will appear correct whether it is a selective fetch (uses the plane selective fetch registers) or a full frame fetch (uses the regular plane registers). Hardware will select between the sets of registers automatically. These registers are double-buffered and armed together with the regular plane and cursor registers.

SEL_FETCH_PLANE_CTL

PLANE_POS instances with SEL_FETCH prefix

PLANE_SIZE instances with SEL_FETCH prefix

PLANE_OFFSET instances with SEL_FETCH prefix

CUR_CTL instances with SEL_FETCH prefix

The plane selective fetch registers are programmed with the adjusted size and position of the planes, reduced down to the update region (must be the full width, accumulated, bounding box).

The plane adjustment calculations here are assuming the update region is relative to this plane's frame buffer. If the update is coming from the cursor or another plane, the position of cursor or other plane relative to this plane's frame buffer has to be calculated as the update region, or else the other plane and cursor changes can be simplified to do a full frame fetch if they are relatively infrequent. Other methods can be used to calculate using different starting coordinates.

For each plane

- SEL_FETCH_PLANE_OFFSET Start Y Position = first line of update region relative to start of frame buffer for this plane
- Update offset within this plane = update region vertical offset in this plane = SEL_FETCH_PLANE_OFFSET Start Y Position - PLANE_OFFSET Start Y Position
- SEL_FETCH_PLANE_SIZE Height = vertical size of update region within this plane
- SEL_FETCH_PLANE_POS Y Position = PLANE_POS Y Position + Update offset within this plane
- SEL_FETCH_PLANE_CTL Selective Fetch Plane Enable = If update region is within this plane ? Enable : Disable
    - This plane is disabled when the update region is fully outside of this plane.
- The plane width/X/horizontal values of the position, size, and offset are not changed with selective fetch, so program those fields the same in the normal plane registers and the selective fetch plane registers.

For cursor

- SEL_FETCH_CUR_CTL Cursor Mode Select = If update region, translated to pipe source coordinates, overlaps this cursor ? CUR_CTL Cursor Mode Select : Disable
    - Cursor size is not adjusted. Cursor is just disabled when the update region is fully outside of cursor.
    - Program the other fields in SEL_FETCH_CUR_CTL to match CUR_CTL.

Selective Update

The selective fetch programming must be combined with panel selective update (SU) programming so that only the selective fetch update region is sent to the panel.

Calculate the update region translated to transcoder vertical active coordinates, then program **PSR2_MAN_TRK_CTL** with that SU region.

- Depending on the project generation, the SU region address is programmed with blocks of either 4 line or 1 line granularity, and with different starting and ending behavior, as noted in the manual tracking register.
- PSR2_MAN_TRK_CTL SF Continuous Full Frame and SF Single Full Frame must be 0 for the SU region to be used.

Full Frame Updates

Sometimes software needs to send a full frame update, such as when async flips happen.

- Software sets PSR2_MAN_TRK_CTL SF Single Full Frame to trigger one full frame to be sent. Hardware will clear the bit after sending the frame.
- Software sets PSR2_MAN_TRK_CTL SF Continuous Full Frame to trigger full frames to be continuously sent until software clears the bit.
- The full frame fields do not cause a frame to be sent, they only set the frame to full size. To send a frame a flip or transcoder push is still needed.

When a full frame is sent, hardware uses the regular plane and cursor registers and not the SEL_FETCH registers, and sets the update region to the full frame, ignoring the programmed SU region.

Hardware will spontaneously send full frame updates on PSR exit, without software necessarily being aware of it, so the regular plane and cursor registers must always be programmed for the full frame.

DPST Handling

The DPST histogram is incorrect when used with selective fetch. DPST will usually give more power savings than selective fetch. Software can still use DPST with selective fetch, at least some of the time, by enabling the histogram only on selected frames (chosen periodicially or algorithmically) and triggering selective fetch full frames while taking the histogram. Based on the histogram result, software can decide if the histogram needs to be taken more frequently for better power savings, with more full frames.

Selective Fetch Programming Sequence

1. DisplayPort enable mode set sequence.
2. For PSR2, configure PSR2_MAN_TRK_CTL SF Partial Frame Enable=1, and depending on project, PSR2_MAN_TRK_CTL PSR2 Manual Tracking Enable=1, then enable PSR2_CTL.
3. For each screen update
    1. If selective fetch for this frame, atomically update planes, cursor, selective fetch, and selective update registers, referring to the Adjusting Plane and Cursor Size and Position and Selective Update sections for the values.
        - All the registers must update atomically together in the same frame. Refer to the Double Buffer Control section, sequence for synchronizing double buffer updates.
            - The fields to allow double buffer stalling are located in PSR2_MAN_TRK_CTL, regular plane control, and regular cursor control registers.
        - The regular plane and cursor registers must be programmed for the full frame size because hardware can spontaneously send a full frame update.
    2. Else, send a full frame update, referring to the Full Frame Updates section.

YUV 4:2:0 Support

Overview

DP and HDMI ports support YUV 4:2:0 output.

YUV 4:2:0 has two modes of operation - bypass mode and full blend mode. Switching between full blend and bypass mode is supported at frame boundaries.

Enabling or disabling YUV 4:2:0 pipe output requires a mode-set.

Full blend mode (HDMI)

In this mode the complete display pipeline is enabled. Input data format can be YUV or RGB. Software has to ensure that the color space is YUV before post blender scaling, since the post blender scaler is only going to be doing the subsampling from YUV 4:4:4 to YUV 4:2:0 (Y & UV scaling). Post blender Y and UV scalers will be used in 5x3 configuration (horizontal taps = 5, vertical taps = 3). A packer block will pack the YUV 4:2:0 data as needed on the HDMI link.

YUV Full blend mode programming requirements (HDMI)

- A scaler should be enabled and bound to pipe.
- The pipe scaler supports downscaling to less than 1.5 (source/destination) in the horizontal direction. However, the pipe scaler can only support downscaling of 1.0 or less in the vertical direction (i.e. no downscaling) without the risk of underflows. A vertical scale factor between 1.0 and 1.5 (non-inclusive) could result in underflows.
- The pipe vertical active display size should be a multiple of 2.
- The horizontal window size must meet the HDMI restriction of a minimum of 128 Y component transfers per scan line.

Additional restrictions (HDMI)

- When YCbCr 4:2:0 pixel encoding is active, pixel repetition is not permitted.
- The transport of 4:2:0 pixels for interlaced video formats is not supported.
- The horizontal active, sync start, sync end, and total should be a multiple of 4 for 8/10/12 bpc.
-

Full blend mode (DP)

In the case of DP/eDP data will be formatted for YUV 4:2:0 before the pixel shifter. Operation is otherwise the same as for Full blend mode with HDMI.

Additional restrictions (DP)

- The transport of 4:2:0 pixels for interlaced video formats is not supported. The other HDMI additional restrictions do not apply.
- This mode is intended for use with external DP to HDMI converters, so VRR, MST, and DP port sync mode are not supported with it.

Bypass mode (HDMI)

In this mode the display pipeline is completely bypassed. YUV 4:2:0 planar data is fetched from memory, then packed according to the YUV 4:2:0 requirements of HDMI 2.0. All the display features in the pipeline including rotation, horizontal flip, blending, plane scaling, and pipe scaling, filtering, dithering, and range correction will not be supported and should not be enabled by software.

Plane size must match pipe active size when bypass mode is enabled.

Only one plane on the pipe can be enabled when bypass mode is enabled.

PIPE_MISC Pixel Rounding must be set to Truncate.

Use only plane 1 for UV and plane 6 for Y

Bypass mode (DP)

In this mode the display pipeline is completely bypassed. YUV 4:2:0 planar data is fetched from memory, then packed according to the YUV 4:2:0 requirements of DP 1.3. Operation and restrictions are otherwise the same as for Bypass mode with HDMI.

Transcoder Video Data Island Packet

Data Island Packet (DIP) is a mechanism that allows data to be sent over a digital port during blanking, according to the HDMI and DisplayPort specifications. This includes header, payload, checksum, and ECC information.

Each type of Video DIP will be sent once each frame while it is enabled.

The audio subsystem is also capable of sending Data Island Packets. These packets are programmed by the audio driver and can be read by in MMIO space via the audio control state and audio HDMI widget data island registers.

Video DIP data write sequence:

1. Wait for 1 VSync to ensure completion of any pending video DIP transmissions
2. Disable the video DIP being updated (disable VDSC before updating PPS DIP)
3. Program video DIP data buffer registers for DIP being updated
4. Enable the video DIP

For MMIO programming of dynamic DIPs, Video DIP write sequence is as follows.

1. Wait to be outside the VBlank region so the following programming does not happen during the VBlank.
2. Program video DIP data buffer registers for DIP being updated.

The video DIP data and ECC buffers may be read at any time.

DIP data buffer registers must be programmed with valid data before enabling the DIP.

Partial DIPs are never sent out while the port is enabled. Disabling the DIP at the same time it is being transferred will result in the DIP being completed before the function is disabled.

Shutting off the port on which DIP is being transmitted will result in partial transfer of DIP data. There is no need to switch off the DIP enable bit if the port transmitting DIP is disabled.

When disabling both the DIP port and DIP transmission, first disable DIP and then disable the transcoder before the transcoder clock select is set to none.

Enabling a DIP function at the same time that the DIP would have been sent out (had it already been enabled) will result in the DIP being sent on the following frame.

For HDMI, even if no DIP is enabled, a single Null DIP will be sent at the same point in the stream that DIP packets would have been sent.

Notes on DIP use cases

GMP DIP can be used to transmit the CEA infoframe SDP since it allows full packet header customization.

There is no assumption in HW on the content of the SDPs (except when PSR is enabled).

For all non PSR cases HW transmits SDP using data programmed in the registers.

The controller does not use the data internally.

PPS is a unique packet as it is 128 bytes of data. No other SDP has this length.

The GMP is what is recommended for HDR metadata.

The VSC may also need to be transmitted with HDR content as it contains colorimetry information.

VSC Extension SDP Packets

VSC_EXT_SDP_CTL

VSC_EXT_SDP_CONF

VSC_EXT_SDP_HEADER

VSC_EXT_SDP_DATA

VSC extension packets can support frame synchronous meta data up to 1K bytes. VSC extension SDP packets add capability to support HDR Dynamic Meta Data. HDR dynamic meta data is supported for full frame updates only.

Key Assumptions

- Software should always write metadata in multiples of 8 DWs i.e., enough data to form one SDP packet.
- Hardware does not support padding of incomplete SDP packets.
- DP driver software has to determine whether a particular audio mode can be supported when transmitting extension packets.
- When Audio is enabled Meta Data will be sent only in horizontal active period of vblank.
- When Audio is disabled Meta Data will be sent both in horizontal active and horizontal blanking period of vblank.
- DSB or software should program the metadata and/or set the buffer ready bits when the relevant frame has started.
- Transcoder sends metadata in vblank region as long as at least one buffer is not empty and respective buffer done indication is set.
- Software should not start a new chain in the buffer while the previous chain data is still pending.
- If the chain doesn't fit in one buffer then software can continue to write the data to second buffer in ping-pong fashion. However, packet straddling across buffers is not allowed.
- DSB can continue writing to a buffer until either the chain is complete or 1KB data is programmed.

- If software doesn't set Index auto increment bit then it should program control register with correct index value prior to each data buffer write.
- If software doesn't set Index auto increment bit and start writing from non-zero index then it is the responsibility of software to send as much data as it can fit in (256- Index) entries. Hardware will however start reading from index0 (and continue to read till the pointers match).
- Index value rolls over after reaching maximum possible value.

- Transcoder clock must be enabled while VSC_EXT_SDP_CTL is enabled or VSC_EXT_SDP_DATA is being written.

- TRANS_DDI_FUNC_CTL must be enabled while VSC_EXT_SDP_DATA is being written.

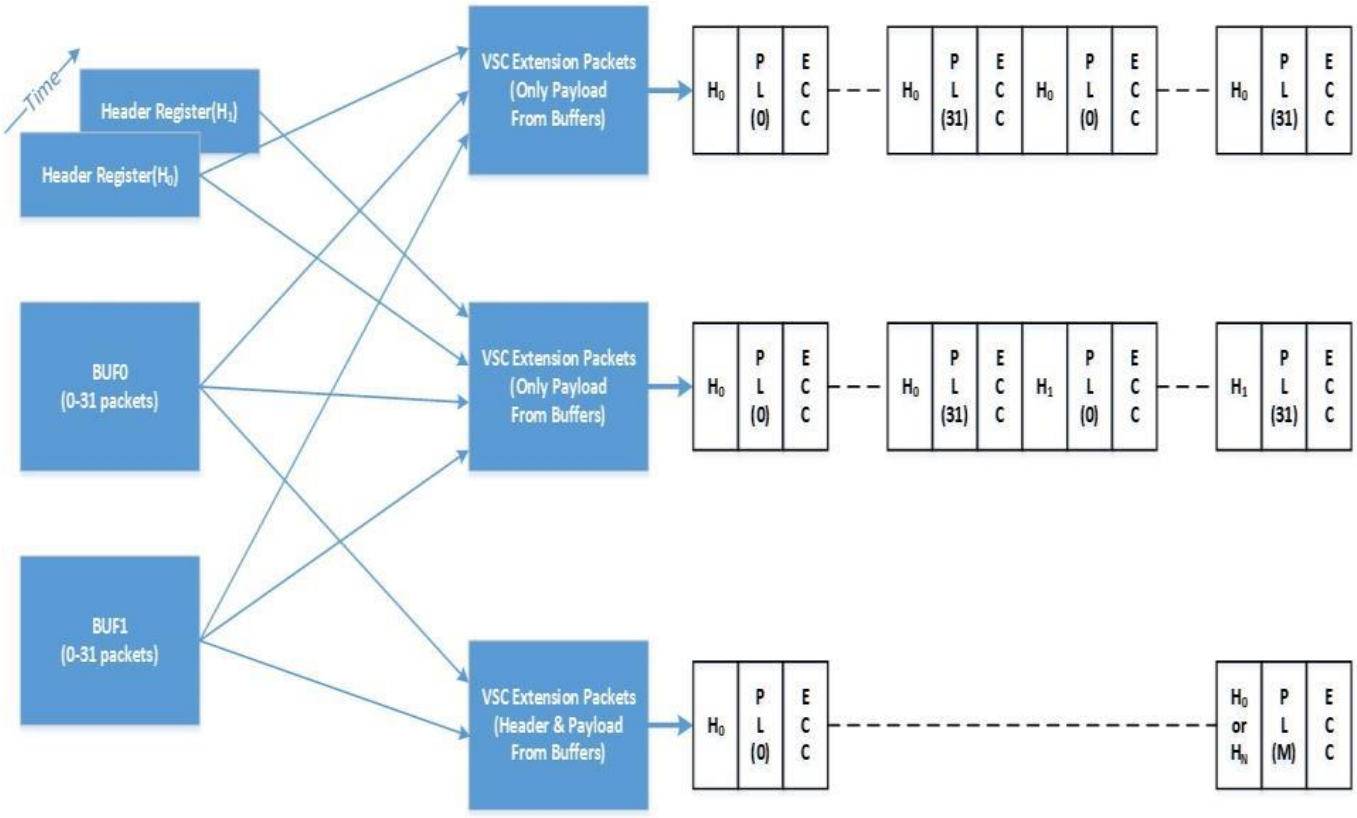
Programming sequence

There are 3 different ways of programming VSC extension packets based on the following considerations.

1. Packet header is from register and payload in buffer
2. Packet header and payload in buffer
3. Multiple VSC extension headers per frame with multiple chains per header

Type of Sequence	Max packets per Buffer
Only payload in buffer	32
Header and payload in buffer	28

The diagram below shows the final VSC extension packets from these 3 different programming methods.



Packet header is from register

In this use case, steps to program any buffer (BUF0 or BUF1) or as follows.

1. Program CTL Register - Auto Index Increment in VSC_EXT_SDP_CTL_0 [14] (VSC_EXT_SDP_CTL_1 [14]) or register bit.
2. Program BUF Register - Meta Data in VSC_EXT_SDP_DATA_0 (or VSC_EXT_SDP_DATA_1) register.
3. Set BUF ready bit - VSC EXT_SDP_CTL0 [16] (or VSC_EXT_SDP_CTL1[16])

The complete sequence is as follows.

1. Program number of packets per chain in VSC_EXT_SDP_CONF[9:0] register.
2. Program Header values in VSC_EXT_SDP_HEADER register.
3. Program BUF0
4. Program BUF1 if needed (payload > 1 KB)
5. Repeat steps 3 and 4 after poll/wait for corresponding BUF empty indication - VSC_EXT_SDP_CTL0[24] (or VSC_EXT_SDP_CTL1[24])

Packet header is from buffer

The number of packets per chain is implicit in the buffer.

In this use case, steps to program any buffer (BUF0 or BUF1) or as follows.

1. Program CTL Register - Auto Index Increment in VSC_EXT_SDP_CTL0 [14] (VSC_EXT_SDP_CTL1 [14]) or register bit.
2. Program BUF Register - Header & Meta Data in VSC_EXT_SDP_Data0 (or VSC_EXT_SDP_Data1) register.
3. Set BUF ready bit - VSC_EXT_SDP_CTL0 [16] (or VSC_EXT_SDP_CTL1[16])

To set this up, program "middle of chaining" bit in the header to '1' and enable "block mode" in VSC_EXT_SDP_DATA_MISC[22].

1. Program BUF0
2. Program BUF1 if needed (payload > 1 KB)
3. Poll/Wait for BUF0 Empty indication - VSC_EXT_SDP_CTL0 [24] .
4. Poll/Wait for BUF1 Empty indication - VSC_EXT_SDP_CTL1 [24] if BUF1 is programmed.
5. Repeat steps 1 to 4 until entire metadata is transmitted.

Multiple headers per frame

In this use case, steps to program any buffer (BUF0 or BUF1) are as follows.

1. Program CTL Register - Auto Index Increment in VSC_EXT_SDP_CTL0 [14] (VSC_EXT_SDP_CTL1 [14]) or register bit.
2. Program BUF Register - Meta Data in VSC_EXT_SDP_Data0 (or VSC_EXT_SDP_Data1) register.

3. Set BUF ready bit - VSC_EXT_SDP_CTL0 [16] (or VSC_EXT_SDP_CTL1[16]) .

The driver will program multiple chains with different number of packets and different header for each chain. As it requires programming of multiple headers per frame, driver has to poll for Chain done bit to avoid overwriting header register before hardware consumes it. Polling of Chain done instruction should be inserted after the programming of entire meta data for each chain is complete.

1. Program number of packets per chain in VSC_EXT_SDP_CONF[9:0] register.
2. Program Header Register - Header values in VSC_EXT_SDP_HEADER register.
3. Program BUF0
4. Program BUF1 if needed (payload per chain > 1 KB)
5. Poll/Wait for BUF0 Empty indication - VSC_EXT_SDP_CTL0 [24] .
6. Poll/Wait for Chain Done indication - VSC_EXT_SDP_CONF[31]
7. If BUF0 is empty but Chain is not done, poll/wait for BUF1 Empty indication. Otherwise, go to step 8.
8. Repeat steps 1 to 7 above until entire meta data is programmed.

DSB side programming considerations

If DSB is being used to program metadata with polling for buffer empty, then the DSB polling timeout (100 uS) will need to be increased, recommending >=500us if metadata programming is started in vblank, or >=frame time if metadata programming is started in vertical active.

Transcoder DDI Function

TRANS_DDI_FUNC_CTL

TRANS_MSA_MISC

TRANS_DDI_FUNC_CTL2

Panel Self Refresh

This section is about Panel Self Refresh (PSR). PSR1 at one point was named Self Refreshing Display (SRD).

PSR1 enable sequence:

- Prerequisite: The associated transcoder and port are running and Aux channel associated with this port has IO power enabled.
- Prerequisite: The associated transcoder, port and at least one plane are running.

1. Configure FBC host and render tracking. The FBC function does not need to be enabled in FBC_CTL.
2. Program Transcoder EDP VSC DIP data with a valid setting for SRD/PSR.
3. Configure and enable SRD_CTL.

PSR1 disable sequence:

- Prerequisite: The associated transcoder and port are running.

1. Disable SRD_CTL.
2. Wait for SRD_STATUS to show SRD is Idle. This will take up to one full frame time (1/refresh rate), plus SRD exit training time (max of 6ms), plus SRD aux channel handshake (max of 1.5ms).

Adaptive Sync Frame Update (ASFU) combines PSR link disable mode, VRR, and PSR single frame update. ASFU allows the vertical blank size to vary as it does for VRR, but then it will enter PSR link disable after the maximum vertical blank, and on PSR exit it can send a single frame before re-entering link disable.

ASFU enable sequence:

- Prerequisite: The associated transcoder and port are running.
- Prerequisite: The associated transcoder, port and at least one plane are running.

1. If SRD_CTL Adaptive Sync Frame Update was not disabled in step 3 of the previous ASFU disable sequence, then disable it.
2. Configure FBC host and render tracking. The FBC function does not need to be enabled in FBC_CTL.
3. Enable VRR - see Transcoder VRR Function chapter
4. Program Transcoder EDP VSC DIP data with a valid setting for SRD/PSR.
5. Configure PSR/SRD Registers and set SRD_CTL Adaptive Sync Frame Update.
6. Set masking bits for PSR to use the VRR push mode
    - PIPE_MISC[Change Mask for Register Write] to '1'
    - PIPE_MISC2[ASFU Flip exception] to '1'.
    - PIPE A: 0x420B0[11] to '1' to mask flips from being frame update events
    - PIPE B: 0x420B4[11] to '1' to mask flips from being frame update events
    - PIPE C: 0x420B8[11] to '1' to mask flips from being frame update events
    - PIPE D: 0x420BC[11] to '1' to mask flips from being frame update events
7. Enable bit 31 of SRD_CTL.

Note that ASFU can be used together with VRR flip line. See the Transcoder VRR Function page for flip line programming since that can be used independent of PSR and ASFU.

ASFU disable sequence:

- Prerequisite: The associated transcoder and port are running.
- Prerequisite: The associated transcoder, port and at least one plane are running.

1. Disable SRD_CTL bit 31.
2. Wait for SRD_STATUS to show SRD is in Idle. This will take up to one full frame time (1/refresh rate), plus SRD exit training time (max of 6ms), plus SRD aux channel handshake (max of 1.5ms).
3. Disable SRD_CTL Adaptive Sync Frame Update, or alternatively, SRD_CTL Adaptive Sync Frame Update can remain enabled until the next ASFU enable sequence is entered.
4. Disable VRR - see Transcoder VRR Function chapter

PSR2 enable sequence:

Prerequisite: The associated transcoder and port are running and Aux channel associated with this port has IO power enabled.

Prerequisite: The associated transcoder, port and at least one plane are running.

1. Configure FBC host and render tracking. The FBC function does not need to be enabled in FBC_CTL.
2. Program Transcoder EDP VSC DIP header with a valid setting for PSR2 and configure VIDEO_DIP_CTL VSC fields.
3. Enable GTC/Aux Frame Sync, if required.
4. Program Aux control register Fast Wake Sync Pulse Count to 8 pulses.
5. Configure Idle Frame, Selective Update Tracking Enable, and Y-coordinate fields, and enable PSR2_CTL.

When configuring PSR2_CTL, also configure the Fast Wake and IO Buffer Wake fields

- IO buffer wake lines = ROUNDUP(PSR2 IO wake time / total line time in microseconds)
- Fast wake lines = ROUNDUP(10us Aux Sync Pattern + 32 microseconds Aux PHY_WAKE transaction time / total line time in microseconds)
    - eDP standard calculation for Aux maximum Fast Wake from FW_SLEEP: 8us Aux preamble + 4us PHY_WAKE pattern + 20us tFW_EXIT_LATENCY
- For both fields limit the minimum to 7 lines and maximum to 12 lines

PSR2 IO wake time = 10us PHY latency + 32us eDP standard maximum Fast Wake from FW_SLEEP

- eDP standard calculation for IO maximum Fast Wake from FW_SLEEP: 11us of valid 8b/10b symbols during Aux preamble and first part of PHY_WAKE pattern + 1us tML_PHY_LOCKsu + 20us tFW_EXIT_LATENCY = 32us

This maximum of 12 lines with 42 wake means PSR2 requires total line time of at least 3.5us.

Panels with relaxed requirements may allow the wake times to be customized.

PSR2 disable sequence:

1. Program PSR2_CTL to clear PSR2 Enable.
2. Disable GTC if required.
3. Wait for PSR2_STATUS to show PSR2 is Idle. This will take up to one full frame time (1/refresh rate), plus exit training time (max of 6ms), plus aux channel handshake (max of 1.5ms), plus one more full frame time if exit began while in a capture frame.
4. If not LRR: Program PSR2_CTL to clear Selective Update Tracking Enable.

Do not enable PSR2 if (TRANS_VBLANK Vertical Blank Start - TRANS_VBLANK Vertical Blank End) < PSR2_CTL Block Count Number value in lines.

This minimum number of lines is required to give time to wake the IO when there is an update starting from the first active line.

This minimum block count of 8 lines means PSR2 requires vblank to be at least 8 lines.

WD_27_M
WD_27_N

WD is a transcoder for capturing display pipe pixel output to memory. It is generally intended for wireless display, but can be used for other functions.

Like the transcoders for wired ports, WD has a timing generator that initiates each frame, and it formats pipe pixel data output. Unlike wired ports, it does not pass the formatted pixel data to DDI or other port logic, but instead writes it to memory.

The WD timing generator uses TRANS_HTOTAL Horizontal Active and TRANS_VTOTAL Vertical Active to define the active pixel area that is written to memory, with the WD_SURF and WD_STRIDE specifying the memory surface attributes.

The maximum resolution is 3840x2160 60Hz, with any capture color format.

Setup

Enable WD following the Sequences for WD - Enable Sequence, and set TRANS_WD_FUNC_CTL Triggered Capture Mode Enable before or at the same time the WD Function Enable it set. This will put WD into the Triggered Capture Mode where it will wait for a capture to be triggered.

Running (after setup)

1. Trigger a frame capture by writing TRANS_WD_FUNC_CTL with the intended Frame Number and Start Trigger Frame = 1. The vertical blank will start, causing double buffered registers to update, and then capture will begin.
2. Find when capture completes by polling WD_FRAME_STATUS Frame Complete or waiting for WD Frame Complete interrupt.
    - There is no hardware timeout for the triggered capture mode. If capture does not complete within 50 milliseconds, write 1 to TRANS_WD_FUNC_CTL Stop Trigger Frame, then correct the configuration before starting another capture.
3. If using WD_FRAME_STATUS Frame Complete to find the frame completion, write 1 to that field to clear it in preparation for the next frame.
4. If another frame is needed
    a. Update any configuration that needs to be changed for the next frame; like WD_SURF, WD_STRIDE, or pipe and plane double-buffered registers.
    b. Goto 1, using an incremented Frame Number

Do not trigger a frame capture in the last frame when disabling WD. Wait for the last capture frame to finish, or hang and timeout, before disabling WD.

The frame number is used to synchronize capture and encode. Software selects the frame number and starts the capture with it. Transcoder WD includes the frame number in the pointer message sent to the encoder. The encoder reads that to align itself to the correct frame. The frame number should increment on each captured frame.

Selective Update

If only a portion of the screen is changing, WD can be configured to selectively update just that region in the capture buffer, saving power and bandwidth. VDenc will process the full buffer, or a portion, depending on its requirements.

The first capture is full frame size to establish the base image, then subsequent captures can be a selective update region.

The selective update region must be 16 line aligned to match pointer granularity.

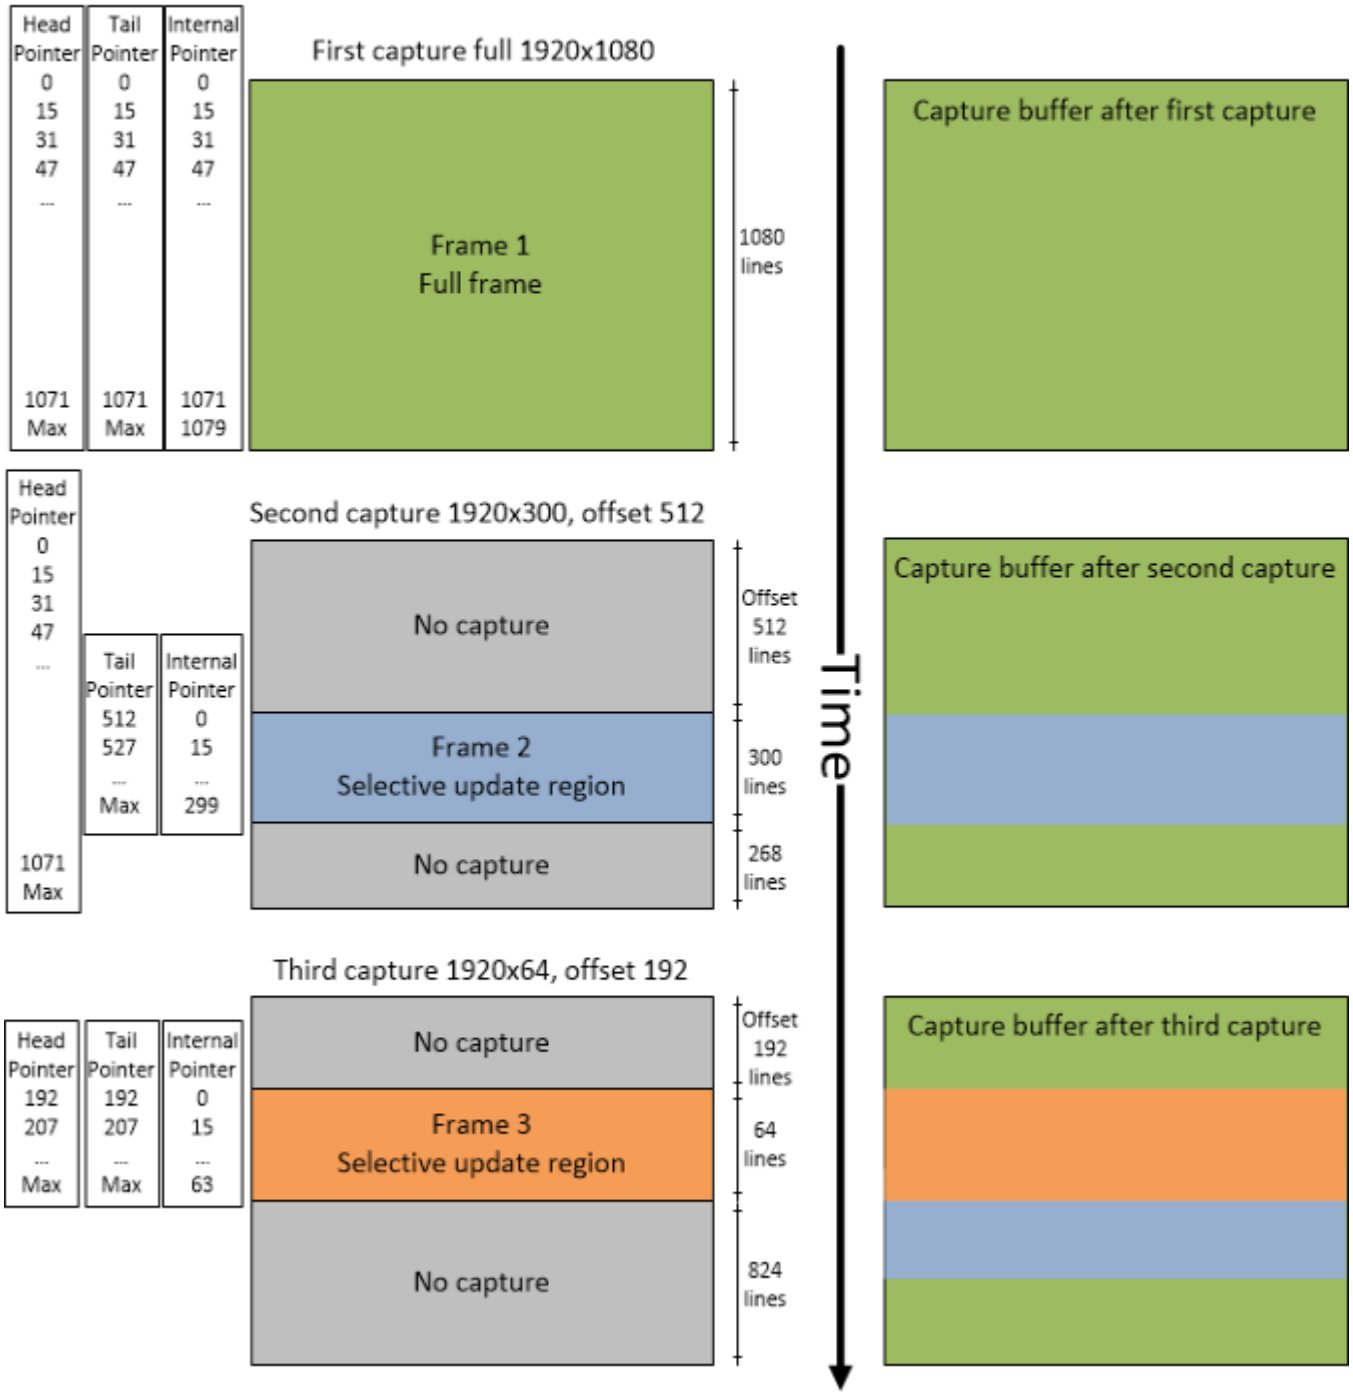
WD applies a programmable offset to the tail pointer to align the pointer to the selective update region within the full frame.

VDenc head pointer is always relative to the start of the full frame.

Programming for selective update region

- Program WD_TAIL_CFG2 Tail Pointer Offset to the number of lines offset from start of the frame to the selective update region, with 16 line granularity.
- Increase surface address to align to the start of the selective update region, with 16 line granularity.
- Reduce pipe and transcoder vertical sizes to match the size of the update region.
- Adjust plane size, position, and vertical panning to align with the update region.

Selective Update Example



Transcoder Port Sync

Feature Description

PORT SYNC is a transcoder level feature. This mode forces two or more transcoders to be in sync with one transcoder primary and one or more transcoder secondaries. In the case of DP/eDP, the primary is unaware that it is operating in Port Sync mode. Only the secondary is aware that it is operating in this mode. Hence, port sync mode is only enabled in the secondary transcoder.

Port Sync mode can be enabled with both DisplayPort SST and MST.

DP/eDP Port Sync Restrictions

1. The secondary and primary transcoders and associated ports must have identical parameters and properties.
2. They must have the same color format, link width (number of lanes enabled), resolution, refresh rate, dot clock, TU size, M and N programming, etc.
3. PSR/PSR2/ASFU/ASU would need to be disabled when port sync mode is enabled.
4. Port Sync Mode Primary Select must be programmed with a valid value when Port sync Mode is enabled.

Port Sync mode on MIPI

When setting up the DSI transcoders for dual link mode (a.k.a. Port Sync Mode) DSI Transcoder 0 is always the primary and DSI Transcoder 1 is always the secondary. The primary transcoder registers will be mirrored to the secondary transcoder when the Port Sync Mode is enabled within the TRANS_DDI_FUNC_CTL register of DSI Transcoder 0 (i.e. the **primary**). The secondary transcoder will ignore the programming within the majority of its registers when Port Sync Mode is enabled within the primary's TRANS_DDI_FUNC_CTL register. The only registers that will not be mirrored between the two transcoders are the registers that allow Software to initiate commands across the DSI Link to the Peripheral.

MIPI Port Sync Restrictions

1. Both DSI transcoders must be connected to the same PLL.

Transcoder Port Sync Support Table

Below is the complete list of primary and secondary transcoders that are supporting this feature.

The 1st column represents the primary transcoders and the 1st row represents the secondary transcoders.

Secondary ->	TC A	TC B	TC C	TC D	TC WD0	TC WD1	TC DSI0	TC DSI1
TC A	N	Y	Y	Y	N	N	N	N
TC B	Y	N	Y	Y	N	N	N	N
TC C	Y	Y	N	Y	N	N	N	N
TC D	Y	Y	Y	N	N	N	N	N
TC WD0	N	N	N	N	N	N	N	N
TC WD1	N	N	N	N	N	N	N	N
TC DSI0	N	N	N	N	N	N	N	Y
TC DSI1	N	N	N	N	N	N	N	N

Multichip Genlock

Cross-feature compatibility

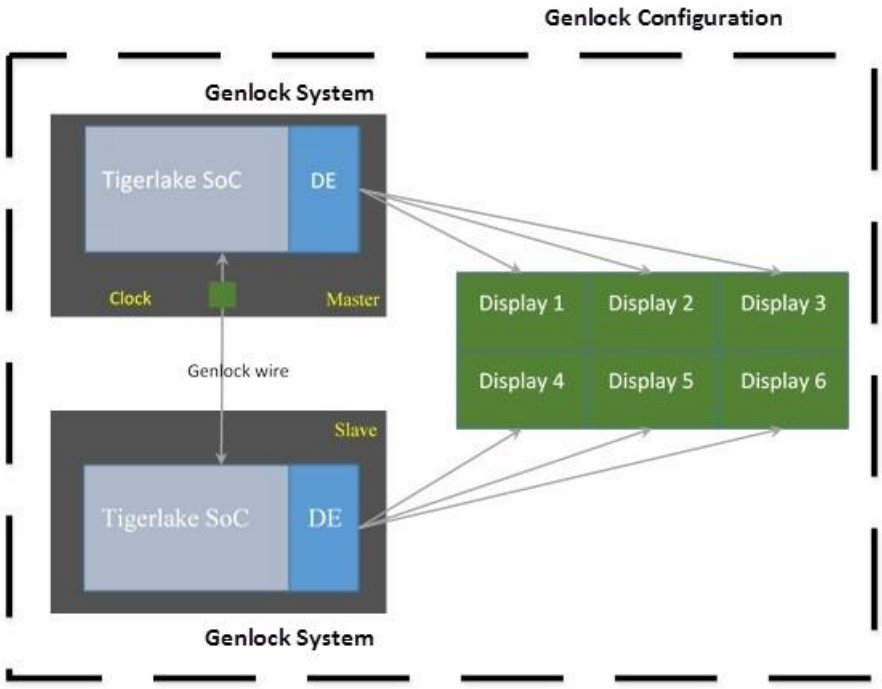
- Multichip genlock does not work with VRR (secondaries do not re-align vblank after enable mode set completes).

Description

With the multichip Genlock feature, platform/application software will synchronize frames (up to N-1 frame) across displays connected to multiple systems. The Nth frame synchronization is what HW portion of this Multi-chip Genlock will accomplish (i.e. all tiles display same scan line of same frame within +/- D pixels, as an example).

Below picture illustrates a wall of 2x3 displays connected to 2 systems in which one acts as genlock primary generating the clock and the other is genlock secondary receiving the clock from primary. DPLLs belonging to display 1, 2 and 3 are using the same PLL reference clock and that same reference clock propagates to DPLLs belonging to display 4, 5 and 6 over genlock wire as shown.

As part of multichip genlock configuration, each Genlock system below guarantees that (a) all display PLLs are running off of the same reference clock and (b) all displays receive their vertical reference (can be a separate wire or combined with reference clock) at the same time. However, flipping the right frame across displays is the responsibility of application software.



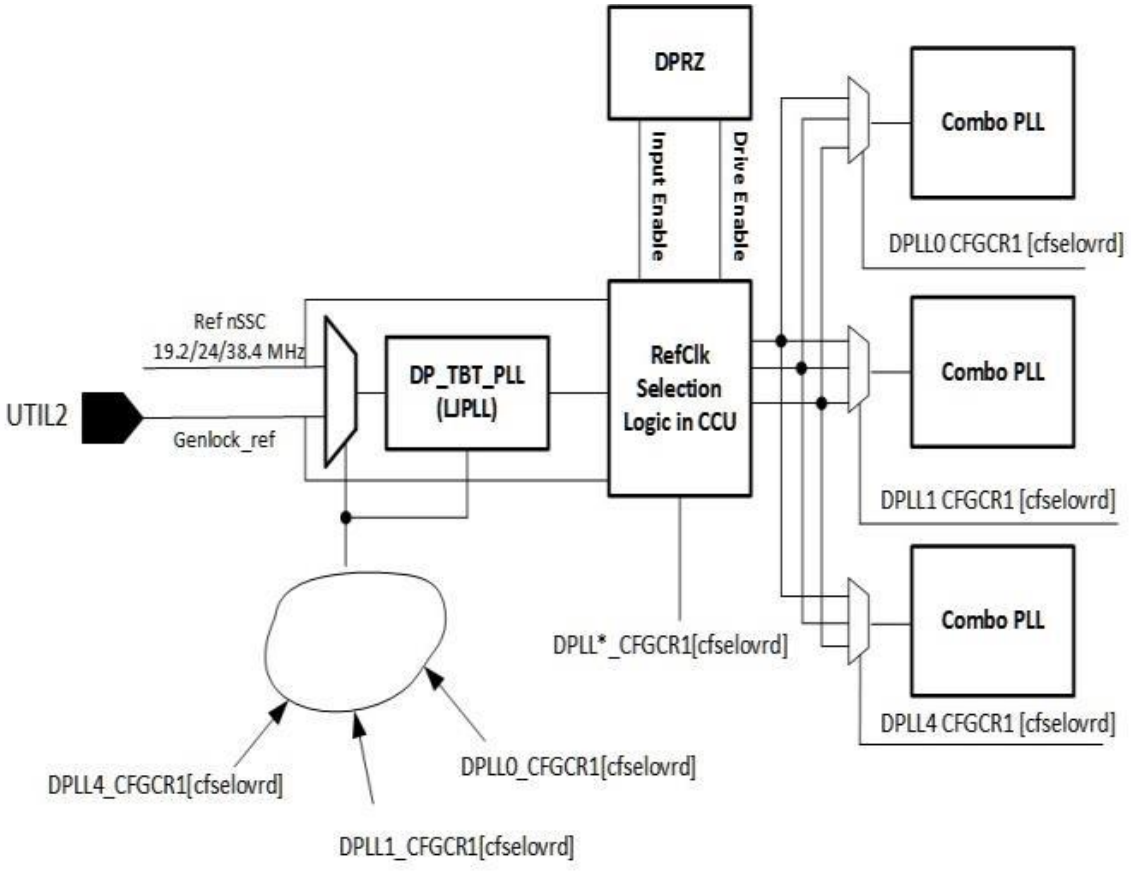
Key functional considerations

- South display is driving genlock enable and direction.
    - BIOS VBT can be configured to target unused GPIO pins.
- Within a genlock configuration, display driver will configure one transcoder as genlock primary (or secondary) and hooks up other transcoders as genlock secondaries.
- Only instances of identical platforms may be genlocked. Different types of platforms may not be mixed in a genlock topology.
    - For example, all platforms must use the same PLL reference clock frequency.
- All displays in a Multichip Genlock system must have the exact same timing requirement and support same transport protocol.
    - As an example, two panels with different 1080p timings are not allowed
- All genlock systems must train their links identically.
- Multichip Genlock is supported with both HDMI and DP (SST only) but not both on the same configuration. DP MST mode is not supported.
- Multichip genlock is not supported with software programmable Vtotal feature (LRR/LRR2).
- After genlock selection is made, chosen system enters genlock primary mode before any other system enters into genlock secondary mode.
    - Both primary and secondary ports finish training and have their transcoder enabled.
    - Primary pipe is enabled.
    - Secondary pipe is enabled.

- Runtime selection of Genlock primary or secondary requires a full mode set.
- Switching PLL reference for multichip Genlock operation requires mode set.
- Modeset across displays connected to the same genlock system can happen in multiple modeset calls.
- Genlock selection is not persistent across reboots.
- A genlock secondary will not generate vblank interrupts until after genlock sync is achieved.
- Genlock secondaries will exit first from genlock secondary mode to default mode before any genlock primary would.
- A genlock primary exits from genlock primary mode to default mode only after all genlock secondaries have switched to default mode.
- Multichip Genlock cannot be enabled at the same time port sync is enabled.
- Note: Genlock hardware may share pins with other mutually exclusive features as follows.

Genlock function	Pin	Pin functionality shared with
Vertical reference (frame sync)	Utility pin 1	MIPI DSI_DE_TE (TE1)
PLL reference clock	Utility pin 2	MIPI DSI_DE_TE2 (TE2)

The genlock reference clock generation for Combo PHY PLLs is shown below. As shown, DPLLs can optionally be filtered by TBT PLL.



Programming

Primary device

- Primary device refers to the display controller that contains the primary transcoder.
- Primary transcoder
  - Primary transcoder outputs the frame sync to be used by local or remote secondaries.
  - TRANS_DDI_FUNC_CTL2 Genlock Enable = 1
  - TRANS_DDI_FUNC_CTL2 Genlock Mode = 10 (Primary)
  - DPLL_CFGCR1[cfselovrd] = 00b (normal XTAL reference)
- Secondary transcoders
  - Secondary transcoders within the primary device are local secondaries.
  - Local secondaries receive frame sync from the primary transcoder in the same device and use the local PLL reference.
  - TRANS_DDI_FUNC_CTL2 Genlock Enable = 1
  - TRANS_DDI_FUNC_CTL2 Genlock Mode = 00 (Local Secondary)
  - DPLL_CFGCR1[cfselovrd] = 00b (normal XTAL reference)
- Pin configuration
  - Frame sync output from primary transcoder to secondary devices
    - UTIL_PIN_CTL Enable = 1
    - UTIL_PIN_CTL Direction = 0 (output)
    - UTIL_PIN_CTL Mode = 0110b (framestart/fsync)
    - UTIL_PIN_CTL Pipe Select = <pipe attached to the primary transcode>
  - Reference clock output to secondary devices
    - UTIL2_PIN_CTL Enable = 1
    - UTIL2_PIN_CTL Direction = 0 (output)

Secondary device

- Secondary device refers to any display controller that contains only secondary transcoders.
- Secondary transcoders
  - Secondary transcoders within the secondary device are remote secondaries.
  - Remote secondaries receive frame sync from the primary transcoder in the primary device and use the primary device PLL reference.
  - Secondary PLL is programmed only after receiving reference clock from the primary device.
  - TRANS_DDI_FUNC_CTL2 Genlock Enable = 1
  - TRANS_DDI_FUNC_CTL2 Genlock Mode = 01 (Remote Secondary)
  - DPLL_CFGCR1[cfselovrd] = 11b (filtered genlock reference)
- Pin configuration
  - Frame sync input from primary device
    - UTIL_PIN_CTL Enable = 1
    - UTIL_PIN_CTL Direction = 1 (input)
  - Reference clock input from primary device

- UTIL2_PIN_CTL Enable = 1
- UTIL2_PIN_CTL Direction = 1 (input)

Sequence to enable a DPLL using filtered genlock reference:

Starting from disabled TBT PLL and DPLL.

1. Configure genlock system to send the genlock reference into this chip
2. Write DPLL CFGCR1 1:0 = 11b (filtered genlock). This automatically sets TBT PLL dividers to the filtered mode and enables TBT PLL.
3. Enable TBTPLL.
4. Poll on TBT PLL lock assertion on the lock signal from CCU to display.
5. Configure DPLL dividers.
6. Enable DPLL.
7. Poll on DPLL lock assertion on the lock signal from CCU to display.

Sequence to disable the DPLL using filtered genlock reference:

1. Disable DPLL.
2. Poll on DPLL lock de-assertion on the lock signal from CCU to display.
3. Write DPLL CFGCR1 1:0 = 00b or 01b. This automatically disables TBT PLL.
4. Disable TBTPLL.
5. Poll on TBT PLL lock de-assertion on the lock signal from CCU to display

Configure genlock system to stop sending the genlock reference into this chip.

Audio

Audio Bios Programming Sequence

Audio Link Settings

When BIOS enables the audio link it must program both the audio controller and audio codec with the same BCLK and T-Mode settings before the link is enabled to ensure enumeration is successful.

In addition the audio codec "Detect Frame Sync Early" value needs to be set per-project in AUD_FREQ_CTL according to the table below.

- The audio codec link setup is performed using the **AUD_FREQ_CTL** register.
  - Program "BCLK" in bits 4:3
  - Program "T-Mode" in bits 15:14
  - Program "Detect Frame sync early" in bits 12:11
  - These settings need to be programmed **before** programming the **AUDIO_PIN_BUF_CTL** register with any analog IO settings.
- The audio controller setup is performed using controller mmio register LCTL (0xc84) and EM1 (0x1000).
  - Please consult with the Audio Controller HW team for official information.
- **For Sx and Connected Standby:**
  - GFX driver programs AUD_FREQ_CTL according to Table 2 below immediately after turning on the power well for audio (PG3).
  - GFX driver disables AUDIO_PIN_BUF_CTL bit 31 after turning off the power well for audio (PG3)

Table 1: *Audio Power Wells*

This table lists the power well containing the audio codec per-project.

Audio Power Well
PG3

Table 2: *Audio Link Settings*

The table below provides the project and stepping specific requirements for the "T-Mode" and "Detect Frame sync early" settings which must be used.

A0		B0 +	
T-Mode	Pull-In Clks	T-Mode	Pull-In Clks
4T	1	8T	0

Codec Verb Table

For each codec present on the High Definition Audio codec link, a corresponding pre-defined "Codec Verb Table" must be available to System BIOS. The Codec Verb Tables are based on codec specific information (coded datasheet) and platform design specific information (schematics) and are built by System BIOS writers and platform designers. The table contains a list of 32-bit Verbs (command and data payload) to be sent to the corresponding codec over the High Definition Audio codec link.

Below is a sample High Definition Audio Codec Verb Table for a platform with 1 codec at codec address 01h.

;Sample HIGH DEFINITION AUDIO Codec Verb Table

;Codec Address (CAd) = 02h

;Codec Vendor: XYZ Company

;VenID DevID:

dd 12345678h

Codec Initialization Programming Sequence

After System BIOS has determined the presence of High Definition Audio codecs, it must follow the programming sequence below to update the codec with the correct jack information specific to the platform for the High Definition Audio driver to retrieve and use later.

There are two ways to send verbs to and receive response data from codecs over the High Definition Audio codec link: using CORB/RIRB (Command Output Ring Buffer / Response Input Ring Buffer) or using the Immediate Command/Immediate Response register pair. The sequence below uses the latter which does not require the availability of a memory buffer.

- System BIOS should ensure that the High Definition Audio HDBAR D27:F0:10-17h contains a valid address value and is enabled by setting D27:F0:04h[1].
- System BIOS must ensure program as mentioned in section 9.6, and then the Controller Reset# bit of Global Control register in memory-mapped space (HDBAR+08h[0]) is set to 1b and read back as 1b.
- When clearing this bit and setting it afterward, System BIOS must ensure that minimum link timing requirements (minimum RESET# assertion time, etc.) are met.
- **Note:** To initialize the codec System BIOS should set the display mmio register 0x65F10 bit 15 to 1b. This bit needs to be set after the controller is brought out of reset.

- The codec requires **50 ms** to come out of reset prior to subsequent operations - System BIOS should wait for the Controller to detect the wake event and recognize the Codec.
- System BIOS can poll on display mmio register 0x65F10 bit 14 "Codec Sleep State" for value 0b (codec awake) with a timeout of **50 ms** before proceeding to additional steps.

For each High Definition Audio codec present as indicated by HDBAR + 0Eh[3:0], System BIOS should perform the codec initialization as described below:

1. Read the VendorID/DeviceID pair from the attached codec.

- Verify that the ICB bit, HDBAR + 68h[0], is 0.
- Write verb 200F0000h (dword) to the IC register, HDBAR + 60h, where: '2' (bits 31:28) represents the codec address (CAd).
- Program HDBAR + 68h[1:0] to 11b to send the verb to the codec.
- Poll the ICB bit, HDBAR+68h[0] until it returns 0 indicating the verb has been sent to the codec. System BIOS may write HDBAR + 68h[0] to a 0 if the bit fails to return to 0 after a **50 us** timeout period.
- If HDBAR + 68h[1] = 1b indicating the response data from the codec is now valid, read HDBAR + 64h; the data is the VID/DID value returned by the codec.

2. Check against internal list to determine if there is a stored verb table which matches the CAd/VID/DID information.

Steps 1 and 2 are System BIOS implementation-specific steps and can be done in different ways. If a System BIOS has prior knowledge of a fixed platform/codec combination (e.g., for a System BIOS having 3 stored verb tables for 3 known codecs at known codec addresses on a known platform), a simple pre-defined codec-to-table matching can be used and steps 1 and 2 can be eliminated. For a System BIOS to support multiple codec/platform combinations, an internal match-list might be needed to match a platform/codec combination to a codec verb table.

3. If there is a match, send the entire list of verbs in the matching verb table one by one to the codec.

- Verify the ICB bit, HDBAR + 68h[0] is 0.
- Write the next verb (dword) in the table to HDBAR + 60h.
- Program HDBAR + 68h[1:0] to 11b to send the verb to codec.
- Poll the ICB bit, HDBAR + 68h[0] until it returns 0 indicating the verb has been sent to the codec. System BIOS may write HDBAR + 68h[0] to a 0 if the bit fails to return to 0 after a **50 us** timeout period.
- Repeat the steps until all the verbs in the table have been sent.

Some verbs in the table may be dependent on certain platform-specific conditions. For example, for the sample table above, the verbs for Pin Complex 7 and 8 (NID=14,16 respectively) should be sent only if the Front Panel Jacks are present and connected on the platform, which may be indicated by a software flag that is controlled by a certain GPIO pin.

Audio Programming Sequence for Link Wakeup

The following audio programming sequences are to be used for preventing the Unsolicited responses when 3 pin link is awake.

Display Audio codec generates a wake event whenever the power well (PGx - power well in which Display Audio codec HW resides) is powered up. If the link is already running, this wake event is considered as unsolicited response by audio controller in PCH. This may sometimes be considered as unnecessary URs. To avoid such URs following programming should be followed by SW. This sequence assumes communication between Audio and GFX drivers without HW to indicate Audio codec power well status.

Power down sequence:

1. Unplug event
2. PD goes low
3. PG2 low
4. Audio link should go low (there should be a communication between GFX driver and Audio Driver to turn off the link)
    1. To turn off iDisp-A link:
    2. Power off iDisp-A codec. Follow the PW2 turn off sequence.
    3. In HD Audio Controller (PCH) Program LCTL1.SPA = 0.
    4. Wait for LCTL1.CPA = 0 to indicate the link has clock stopped.
    5. Clear bit 31 to 0 of AUDIO_PIN_BUF_CTL register.

Power up sequence:

1. Plug event
2. PG2 goes high
3. Audio link to be enabled (there should be a communication between GFX driver and Audio Driver to turn on the link)
    1. To turn on iDisp-A link:
    2. In HD Audio Controller (PCH) Program LCTL1.SPA = 1.
    3. Wait for LCTL1.CPA = 1 to indicate the link has clock running.
    4. Set bit 31 to 1 of AUDIO_PIN_BUF_CTL register.
4. Check WAKESTS[2] = 1 to indicate the codec wake up occurs
5. PD bit set
6. Codec awake. Continue with codec init.

Audio Programming Sequence

The following HDMI and DisplayPort audio programming sequences are to be used when enabling or disabling audio or temporarily disabling audio during a display mode set.

- The audio codec and audio controller disable sequences must be followed prior to disabling the transcoder or port in a display mode set.
- The audio codec and controller enable sequences can be followed after the transcoder is enabled and the port is enabled and completed link training (not sending training or idle patterns if DisplayPort).
- The audio controller and audio codec sequences may be done in parallel or serial. In general, the change in ELDV/PD in the codec sequence will generate an unsolicited response to the audio controller driver to indicate that the controller sequence should start, but other mechanisms may be used. SW should make sure to set the Inactive (IA) bit to 0 before setting PD to 1.

In addition, the Audio Bandwidth Checks page provides algorithms and calculations that must be followed during the enabling sequence for audio, to ensure there is adequate bandwidth available for audio transmission.

Disabling Audio

Audio codec disable sequence:

- Disable sample fabrication
  - Set AUD_MISC_CTRL Sample_Fabrication_EN (bit 2) to "0".
- Disable timestamps
  - Set AUD_CONFIG N_value_index (bit 29) to "0" for HDMI or "1" for DisplayPort.
  - Set N_programming_enable (bit 28) to "1"
  - Set Upper_N_value and Lower_N_value (bits 27:20, 15:4) to all "0"s.
- Disable ELDV and ELD buffer
  - Set AUD_PIN_ELD_CP_VLD ELD_valid (bit 0, 4, or 8 based on which port is used) to "0"
- Wait for 2 vertical blanks
- Optional: Disable audio PD (Presence Detect)
  - Software may choose to skip this in order to keep PD enabled during a resolution switch.
  - Set AUD_PIN_ELD_CP_VLD Audio_Inactive (bit 3, 7, or 11) to "1". SW does not need to set this bit to enable Inactive bit.
  - Set AUD_PIN_ELD_CP_VLD Audio_Output_Enable (bit 2, 6, or 10) to "0".

Audio controller disable sequence:

- Program Stream ID to 0 - Verb ID 706
- Disable audio info frames transmission - Verb ID 732
- Disable Digen - Verb ID 70D
- Program the codec to D3 state if needed.
- Audio driver may stop the audio controller DMA engine at this point if needed, but not required.

Enabling Audio

Pre-Enabling Notes:

The following tables (if present) list any project specific sequence requirements to be handled before initiating the audio codec enable sequence.

Programming Notes
• No additional requirements specified.

Audio codec enable sequence:

- Enable audio Presence Detect
  - Set AUD_PIN_ELD_CP_VLD Audio_Inactive (bit 3, 7, or 11) to "0".
  - Set AUD_PIN_ELD_CP_VLD Audio_Output_Enable (bit 2, 6, or 10) to "1".
- Wait for 1 vertical blank
- Load ELD buffer and Enable ELDV
  - Set AUD_PIN_ELD_CP_VLD ELD_valid (bit 0, 4, or 8 based on which port is used) to "1".
- Enable timestamps
  - Set AUD_CONFIG N_value_index (bit 29) to "0" for HDMI or "1" for DisplayPort.
  - Set N_programming_enable (bit 28) to "0".
  - Program Upper_N_value and Lower_N_value (bits 27:20, 15:4) if a non-default N value is needed.
- Enable sample fabrication if this feature is needed
  - Set AUD_MISC_CTRL Sample_Fabrication_EN (bit 2) to "1".
- Enable sample fabrication if this feature is needed

Audio controller enable sequence:

- Program the codec to D0 state if in D3 state.
- Program Stream ID to non zero - Verb ID 706
- Enable audio info frames transmission - Verb ID 732
- Enable Digen - Verb ID 70D
- If audio controller DMA engine is stopped, audio driver can start the DMA engine at this point.

Audio Hblank early enable sequence:

- Bits 20:18 of the AUD_CONFIG_BE register have the Hblank early enable for each pipe for DP Audio. Bits 27:24 of the AUD_CONFIG_BE register have the Hblank early enable for each pipe for DP Audio. When DP Audio is enabled on that pipe, driver must set these bits when Audio presence detect is set for each of these pipe regardless of the video resolution. This programming is not needed for HDMI Audio.

- For the following cases of VDSC, 4K, 5K and 8K resolutions the following programming sequence needs to be performed by the driver before setting the Audio Presence detect of pipe for DP audio. This is not required for HDMI Audio.

  A. Driver must Program "Hblank Early Enable for Pipe X" = 1b always

  B. Determine required pixel clocks between hblank_early rise and hblank rise

  link_clks_available = {ROUDNDOWN[((h_total - h_active) * (link_clk / pixel_clk) - 28)]}

  link_clks_required = {ROUNDUP[(192000 / (refresh_rate * v_total))]} * ((48/lanes) + 2)

  If link_clks_available > link_clks_required

  - For Step C, use hblank_delta = 32

  else

  - For Step C, use hblank_delta = {ROUNDUP[(((5 / link_clk) + (5 / cdclk)) * pixel_clk)]}

  C. Determine hblank_early programming

  tu_data = (pixel_clk * vdsc_bpp * 8) / (link_clk * lanes * fec_coeff)

  tu_line = ((h_active * link_clk * fec_coeff)/(64 * pixel_clk))

  link_clks_active = (tu_line -1)*64 + tu_data

  hblank_rise =((link_clks_active + 6*{ROUNDDOWN[(link_clks_active / 250)]} + 4) * (pixel_clk/link_clk))

  hblank_early_prog = {ROUNDUP[h_active - hblank_rise + hblank_delta]} (from Step B)

  if (hblank_early_prog < 32) then

  - Program "*Hblank_start count for Pipe X*" to select value 32

  elsif (hblank_early_prog > 32 < 64) then

  - Program "*Hblank_start count for Pipe X*" to select value 64

  elsif (hblank_early_prog > 64 < 96) then

  - Program "*Hblank_start count for Pipe X*" to select value 96

  elsif (hblank_early_prog > 96) then

  - Program "*Hblank_start count for Pipe X*" to select value 128

  D. Calculate samples per line required

  samples_room = {ROUNDDOWN[(((h_total - h_active) * (link_clk / pixel_clk) - 12) / ((48/lanes) + 2))]}

if (samples_room < 3) then

- Program "*Number of samples per line for Pipe X*" to select value == samples_room

else

- Program "*Number of samples per line for Pipe X*" to select value == default value (00b = "All Samples available in buffer")

The following variables are referred to in the equations:

Variable	**Units**	**Note**
h_total	pixels	Total horizontal pixels
h_active	pixels	Active horizontal pixels
v_total	pixels	Total vertical pixels
refresh_rate	Hz	Screen refresh rate
input_bpp	bits per pixel	Bits per color "bpc" setting * 8
vdsc_bpp	bits per pixel	If not using compression, vdsc_bpp = input_bpp
fec_coeff	constant	Currently 0.972261. See "**Transcoder MN Values**".
lanes	lanes	1,2, or 4
link_clk	MHz	Link Rate / 10 (i.e. 162,270,540,810 MHz). See "**Clocks**" page per project.
pixel_clk	MHz	h_total * v_total * refresh_rate
cdclk	MHz	See "**Clocks**" page per project.
link_clks_available	link clocks	Link clocks within hblank available for audio use
link_clks_required	link clocks	Link clocks within hblank needed for audio each line

hblank_delta	pixel clocks	Pixel clocks to maintain between hblank_early_rise and hblank_rise
tu_data	link clocks	Link clocks per TU used for pixel data
tu_line	TUs	TUs required per horizontal line
link_clks_active	link clocks	Link clocks required to send active pixels per horizontal line
hblank_rise	pixel clocks	Pixel clock at which hblank will rise, accounting for FEC
hblank_early_prog	pixel clocks	Pixel clocks required to pull hblank_early back far enough from the end of h_active, to ensure there are hblank_delta pixel clocks before hblank rise.
samples_room	audio samples	Maximum number of samples which can fit within hblank, rounded down.

Audio Bandwidth Checks

This page provides the algorithms and calculations needed to ensure there is sufficient bandwidth available with the enabled video configuration for the transmission of audio.

These checks are broken down into DisplayPort and HDMI specific checks, and each section lists the criteria which determine when each check must be performed.

DisplayPort

The following section lists any required checks for audio bandwidth that are applicable in DisplayPort mode.

DP1 MST with DSC Enabled:

The following algorithm and calculation needs to be applied when DP1 MST + DSC + Audio is enabled.

Algorithm

1. Determine max_output_bpp that is supported per the current lanes, link rate, and video mode.
   - Bspec provides this calculation on the Display DSC page under “Programming Considerations and Restrictions”
2. GFX driver prunes all audio modes from the ELD except minimum audio (48KHz 2ch).
3. Check if minimum audio (48KHz 2ch) can work with max_output_bpp from step 1.

- Use Calculation 1 below, with output_bpp = max_output_bpp, aud_freq_khz = 48, aud_chan = 2, and rest of video settings.
    - IF YES -> Proceed to Step 4
    - IF NO -> Disable DSC

4. Determine the min_output_bpp required to support minimum audio (48KHz 2ch).

- For each vdsc_bpp in [8 to max_output_bpp]:
    - Use Calculation 1 below, with output_bpp = vdsc_bpp[i], aud_freq_khz = 48, aud_chan = 2, and rest of video settings.
    - If audio_supported = True, min_output_bpp = vdsc_bpp[i], loop can be stopped.
    - If audio_supported = False, continue loop with next vdsc_bpp[i+1].

5. Enable DSC using at least min_output_bpp from Step 4.

Calculation 1

Inputs:

link_rate_ghz

lanes

pixel_clk_mhz

output_bpp

hactive_pixels

hblank_pixels

aud_freq_khz

aud_chan

Constants:

mtp_size_clks = 64

link_overhead = 0.03

hblank_bytes_avail_overhead = 48

hblank_bytes_req_overhead = 56

General Calc:

```
link_clk_mhz                = (link_rate_ghz / 10) * 1000
line_freq_khz               = (pixel_clk_mhz / (hactive_pixels + hblank_pixels)) * 1000
pixel_bw_gbps               = (pixel_clk_mhz * (output_bpp / 8)) / 1000
link_bw_gbps                = ((link_clk_mhz * lanes) * (1-link_overhead)) / 1000
mtp_size_ns                 = (mtp_size_clks / link_clk_mhz) * 1000
hblank_size_ns              = (hblank_pixels / pixel_clk_mhz) * 1000
vc_slots          = CEIL[ 64 * (pixel_bw_gbps / link_bw_gbps)]
aud_samples_per_line        = CEIL[ aud_freq_khz / line_freq_khz ] + 1
```

Worst Case Hblank vs Audio BW:

hblank_reduced_ns = hblank_size_ns - (((64 - vc_slots) / link_clk_mhz)*1000)

hblank_slots_full_mtps = FLOOR[hblank_reduced_ns / mtp_size_ns] * vc_slots

hblank_slots_partial_mtps = MIN[CEIL[(MOD[hblank_reduced_ns / mtp_size_ns] * link_clk_mhz) / 1000] , vc_slots]

hblank_slots = hblank_slots_full_mtps + hblank_slots_partial_mtps

```
hblank_bytes_available          = (hblank_slots * lanes) - hblank_bytes_avail_overhead
IF (aud_chan > 2):
     hblank_bytes_required      = (aud_samples_per_line*10 + 4)*4
     + hblank_bytes_req_overhead
ELSE:
     hblank_bytes_required      = (CEIL[aud_samples_per_line/2]*5 + 4)*4
     + hblank_bytes_req_overhead
```

audio_supported = IF hblank_bytes_available > hblank_bytes_required:
YES ELSE: **NO**

HDMI

The following section lists any required checks for audio bandwidth that are applicable in HDMI mode.

Currently no audio bandwidth checks are required.

Audio Silent Stream Programming Sequence

The following sequence must be followed by the Display Audio Codec driver to enable/disable the silent stream. This should be part of stream enabling and disabling sequence as described in the Audio programming sequence page here .

Silent Stream disable flow:

1. Program channel index = 0xF, stream id = 0xF through 0x706 verb.
2. Wait for 100us
3. Program channel index = 0xF, stream id = 0 through 0x706 verb

Silent Stream enable flow:

1. Program channel index = 0xF, stream id = DMA stream id through 0x706 verb.
2. Wait for 100us
3. Program channel index = 0x0, stream id = DMA stream id through 0x706 verb

Audio stream playback disable sequence:

1. Program channel index = 0xF through 0x706 verb.
2. Program Stream ID to 0 - Verb ID 706

3. Disable audio info frames transmission - Verb ID 732
4. Disable Digen - Verb ID 70D
5. Program the codec to D3 state if needed.
6. Audio driver may stop the audio controller DMA engine at this point if needed, but not required.

Audio stream playback enable sequence:

1. Program the codec to D0 state if in D3 state.
2. Program Stream ID to non zero - Verb ID 706
3. Program channel index = "actual value" through 0x706 verb.
4. Enable audio info frames transmission - Verb ID 732
5. Enable Digen - Verb ID 70D
6. If audio controller DMA engine is stopped, audio driver can start the DMA engine at this point.

Audio Codec driver must ensure that there are no stream parameters that get modified when silent stream is enabled. Any stream parameters update can be done only after silent stream is disabled as mentioend above.

DP_TP_CTL

DP_TP_STATUS

Digital Display Interface

Combo PHY DDI Buffer

Overview

This section applies to the DDIs going to the combo PHY. DDIs going to FIA thunderbolt/typeC have separate programming.

Registers

DDI_BUF_CTL
PHY_MISC
PORT_COMP_DW0
PORT_COMP_DW1
PORT_COMP_DW3
PORT_COMP_DW8
PORT_COMP_DW9
PORT_COMP_DW10
PORT_CL_DW5
PORT_CL_DW10
PORT_CL_DW12
PORT_CL_DW15
PORT_CL_DW16
PORT_TX_DW1
PORT_TX_DW2
PORT_TX_DW4
PORT_TX_DW5
PORT_TX_DW6
PORT_TX_DW7
PORT_TX_DW8
PORT_PCS_DW1
PORT_PCS_DW9

The group access address can be used to simultaneously write the same value to a register that has instances in all 4 lanes. This is only for use when the same exact register value is applied to all 4 lanes. Reads using a port group address usually cannot return correct data. For read/modify/write to a group, the read should be to one of the lane addresses, then the write to the group address.

Combo PHY Comp Sources

Certain PHYs are connected to compensation resistors and act as compensation sources. Other PHYs and DPLLs sync to their sources to get compensation values.

A comp source PHY must be initialized before its comp sink PHYs are initialized or DPLLs are enabled, and source must be kept initialized while source or sinks are in use.

Source	Sink(s) to this Source
PHY A	DPLLs*, PHY B, PHY C

*DPLLs now have their own comp, but sink programming should be maintained for commonality with past projects.

Combo PHY Initialization Sequence

The PHY must be initialized before enabling combo PHY DDI IO power or Aux IO power. It can be initialized as early as the full display initialization sequence.

DDIA PHY initialization state will be preserved across DC6. Depending on project and SKU, other DDIs may not be preserved and then must be re-initialized for use after DC6 is disabled.

1. If **PORT_COMP_DW0** Comp Init == 1b, skip the rest of this sequence since it is already initialized
2. **DCC susclk divider programming**

   PORT_TX_DW8

   Program PORT_TX_DW8[odcc_clk_sel] to "1" and PORT_TX_DW8[odcc_clk_div_sel[1:0]] to "00".

   DCC continuous mode

   PORT_PCS_DW1

   Program PORT_PCS_DW1[DCC Mode Select] to DCC continuous mode.
3. Clear **PHY_MISC_<DDI that maps to this PHY>** DE to IO Comp Pwr Down to 0b. Skip this step if this DDI does not have a PHY_MISC register instance.
4. Program procmon reference values in **PORT_COMP_DW1**, **PORT_COMP_DW9**, and **PORT_COMP_DW10**.
   - Procmon Reference Values

Voltage	0.85V	0.85V	0.95V	0.95V	1.05V	1.05V
Register/Process	dot-0	dot-1	dot-0	dot-1	dot-0	dot-1
PORT_COMP_DW1 [7:0]	0x00	N/A	0x00	0x00	0x00	0x00
PORT_COMP_DW1 [23:16]	0x00	N/A	0x00	0x00	0x00	0x44
PORT_COMP_DW9 [31:0]	0x62AB67BB	N/A	0x86E172C7	0x93F87FE1	0x98FA82DD	0x9A00AB25
PORT_COMP_DW10 [31:0]	0x51914F96	N/A	0x77CA5EAB	0x8AE871C5	0x89E46DC1	0x8AE38FF1

Voltage and process are found in **PORT_COMP_DW3**

5. If this PHY is a comp source, set **PORT_COMP_DW8** irefgen to 1b.
6. Set **PORT_COMP_DW0** Comp Init to 1b.
7. Set **PORT_CL_DW5** CL Power Down Enable to 1b.

Combo PHY Un-Initialization Sequence

The combo PHY only needs to be un-initialized for DC9.

DDIA PHY is the comp source, so it must not be un-initialized if other combo PHYs are in use.

1. Set **PHY_MISC** DE to IO Comp Pwr Down to 1b.
2. Clear **PORT_COMP_DW0** Comp Init to 0b.

If the PHY is needed again, follow the initialization sequence.

Voltage Swing Programming Sequence

This sequence is used to setup the voltage swing before enabling the DDI, as well as for changing the voltage during DisplayPort link training. The voltage swing values are listed in the tables below. Note that the MIPI DSI voltage swing programming is for the high speed data buffers and hardware automatically handles the voltage swing for the low power data buffers.

1. If port type is eDP or DP, set PORT_PCS_DW1 cmnkeeper_enable to 1b, else clear to 0b.
2. Program loadgen select

Loadgen Values	Conditions		
Register	Bit rate <= 6 GHz and 4 lanes enabled	Bit rate <= 6 GHz and 2 or 1 lanes enabled	Bit rate > 6 GHz
PORT_TX_DW4_LN0 Loadgen Select	0	0	0
PORT_TX_DW4_LN1 Loadgen Select	1	1	0
PORT_TX_DW4_LN2 Loadgen Select	1	1	0
PORT_TX_DW4_LN3 Loadgen Select	1	0	0

- Group access cannot be used here since each lane can have a unique value, and any later writes to PORT_TX_DW4 must not use group access so that they don't overwrite the individual lane values.

3. Set PORT_CL_DW5 SUS Clock Config to 11b.
4. Clear training enable to change swing values
   - Clear PORT_TX_DW5 TX Training Enable to 0b
5. Program swing and de-emphasis
   - Values for each port type are listed in voltage swing programming tables below
   - Set PORT_TX_DW5 Scaling Mode Sel to 010b.
   - Set PORT_TX_DW2 Rcomp Scalar to 0x98 hex
   - Set PORT_TX_DW4 Post Cursor 2 to 0x00 hex
   - Set PORT_TX_DW5
     - Rterm Select to 110b
     - 3 Tap Disable to 1
     - Cursor program to 0
     - Coeff Polarity to 0
   - Program the other fields in PORT_TX_DW2, PORT_TX_DW4, PORT_TX_DW5, and PORT_TX_DW7 using the values specified in the table below.
6. Set training enable to trigger update
   - Set PORT_TX_DW5 TX Training Enable to 1b

Voltage Swing Programming

Protocol	Voltage Swing Level[1]	Pre-emphasis Level[1]	Non-transition mV diff p-p	Transition mV diff p-p	Pre-emphasis dB	Swing Sel DW2 binary	N Scalar DW7 hex	Cursor Coeff DW4 hex	Post Cursor 1 DW4 hex	2 Tap Disable DW5

[1]The voltage swing level and pre-emphasis level values follow the naming used in the DisplayPort standard.

[2]eDP extra power optimized setting. This swing setting can be used for eDP HBR2 and lower frequencies if the motherboard has been designed to support it and it is specified through VBT or other OEM selection.

Program the voltage swing as listed in the table and additionally program PORT_CL_DW10 o_edp4k2k_mode_ovrd_en=1 and o_edp4k2k_mode_ovrd_val=1. Program o_edp4k2k_mode_ovrd_val=0 when using any other swing values. If link training fails with this swing, fall back to the regular eDP swing settings.

eDP panels may support lower power, low voltage, swing values using the "eDP" protocol values from the table or higher power, high voltage, swing values using the "DP" protocol values. The selection is generally an OEM decision configured in BIOS VBT.

TypeC PHY DDI Buffer

This programming is used for the typeC PHY when operating in DP alternate mode or the legacy HDMI or DP modes. This programming is not used for thunderbolt as the thunderbolt controller takes care of the PHY programming.

PHY Lane Configuration

The PHY contains 2 lanes, and each lane contains a primary transmitter (TX1) and a secondary transmitter/receiver (TX2 or TX/RX). A single PHY lane can support up to 2 DP or HDMI lanes. Two PHY lanes can be used to support 4 DP or HDMI lanes. Note that the RX function in TX2 is always disabled for DP use cases.

Driver must configure the DP mode to indicate which transmitter is used and voltage swing for each transmitter in use, within each lane in use.

Voltage Swing Programming Sequence

This sequence is used to setup the voltage swing before enabling the DDI, as well as for changing the voltage during DisplayPort link training.

1. Clear DKL_TX_PMD_LANE_SUS_LN0 register if display owns this PHY lane.
2. Clear DKL_TX_PMD_LANE_SUS_LN1 register if display owns this PHY lane.
3. Update registers DKL_TX_DPCNTL0, DKL_TX_DPCNTL1 and DKL_TX_DPCNTL2 registers with appropriate Vswing and de-emphasis levels from table below.
4. Set DKL_TX_DPCNTL2[dp20bitmode] to "0".

DKL_DP_MODE Programming

There are two DP_MODE registers per PHY, one for each PHY lane, containing x1 and x2 fields that are programmed to indicate which transmitter subsystem to enable. The values to program are derived from the pin and lane assignments and port width selection found in the following registers.

- PORT_TX_DFLEXPA1 DPPATC<this port> Display Port Pin Assignment for Type-C Connector
- PORT_TX_DFLEXDPSP DPX4TXLATC<this port> Display Port x4 TX Lane Assignment for Type-C Connector
- DDI_BUF_CTL_<this port> DP Port Width Selection

Orientation flip and lane reversal differences are cancelled out by hardware lane enable signaling shutdown of the unused LN0 or LN1.

DPPATC	DPX4TXLATC	Description	DP Port Width	DP MODE LN1		DP MODE LN0	
				x2_mode	x1_mode	x2_mode	x1_mode

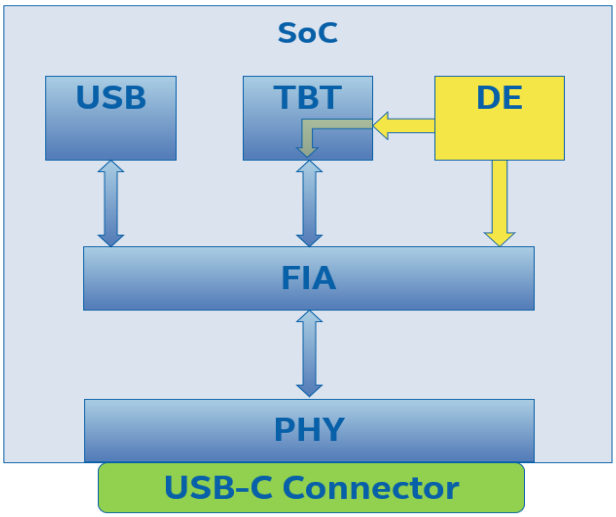
0	0	TX1 (TX)
0	1	TX2 (TX/RX)
1	0	TX1 + TX2
1	1	TX1 + TX2

TypeC Programming

The USB 3.1, thunderbolt 3, and display (DE) controllers are integrated into the CPU. All these controllers connect to Flexi I/O Adapter (FIA) that muxes data and clocks between controllers and the PHY. The PHY contains the IOs and PLLs for the USB-C connector. Display Engine can also output to thunderbolt (TBT) which then goes to FIA and to PHY. During mode enumeration (DE to FIA path for non-TBT), display software takes into account not only the port bandwidth of the DP receiver (monitor) and any intervening DP re-timers, but also the number of DP lanes being driven out of a given USB Type-C port.

TBT does not impose restrictions on number of DP lanes that can be sourced. Display software reads the monitor capabilities, trains the link, and chooses number of DP lanes to be used per current software policies. However, PHY will not need to be programmed or trained. TBT will use a different PLL than the usual combo PHY DDI PLL or PLL, so software will need to be aware of the TBT connector.



Static/Fixed/Legacy/Native DP or HDMI Configuration

A native DP or HDMI connector can be attached to the TypeC PHY to support a static or fixed configuration instead of dynamic typeC. This configuration must be specified in IFWI strap bits which the SoC micro-controller uses to configure each port, and BIOS VBT which display software uses.

Type C DDI Sequence

The main Type-C flows of interest to display controller are

- PD connect flow
- PD disconnect flow
- PD Re-configuration flow

As part of PD connect flow, whenever a new device is connected over the Type-C connector, PD engine detects the presence of the device over the CC channel and identifies the connector orientation. It also configures PHY common lane and data lane to operate in DP mode. At the end of the PD connect flow,

SOC uC (typically called IOM) also programs FIA Pin Assignment registers, and programs FIA registers with pin assignment (PA), link width, live state, etc. Finally, PD connect flow sends HPD to DE.

The type-C PHYs can be shared between multiple controllers; display, USB, etc. As a result, handshaking through FIA registers is required around connect and disconnect to cleanly transfer ownership with the controller and set the type-C power state.

Display software most not use a disconnected port.

FIA registers updated during PD flows

Register	Function
PORT_TX_DFLEXPA1	FIA arranges the 4 DP lanes in Type-C connector based on 6 possible arrangements called pin assignments A-F in VESA DP Type-C spec.
PORT_TX_DFLEXDPPMS PORT_TX_DFLEXDPCSSS PORT_TX_DFLEXDPSP	Communication between SoC uC and display software.
PORT_TX_DFLEXDPMLE1	Display software configures the number of lanes it is using

Port Mapping

The following table highlights mapping from port to FIA instance.

TypeC Port	2 Connector Modular FIA family
Port1	FIA1, connector 0
Port2	FIA1, connector 1
Port3	FIA2, connector 0
Port4	FIA2, connector 1
Port5	FIA3, connector 0
Port6	FIA3, connector 1

The mapping from connector to port is split into groups of 2. For example, the FIA1 DFLEXDPSP1 register fields referring to connectors 0 through 1 map to ports 1 through 2 and the FIA2 DFLEXDPSP1 register fields referring to connectors 0 through 1 maps to ports 3 through 4. The FIA register fields for connectors >1 are reserved.

Type-C Aux Power Requirements

The aux power function is overloaded to control power states in the type-C subsystem.

Aux power must only be enabled while in the connect state. Do not enable Aux power before connect flow or after disconnect flow.

For DP-alternate and thunderbolt, Aux power must be enabled while using Aux channel or main link (enable mode set) and it should be disabled at other times to save power.

For static/fixed/legacy/native, for DP and for HDMI, it must be enabled during the connect flow and not disabled until disconnect flow.

For every typeC port (static/fixed/legacy/native and DP-alternate, but not thunderbolt), after enabling aux power request and receiving aux power ack, wait for uc_health bit (Dekel PHY register DKL_CMN_UC_DW27 @BASE + 0x236c bit [15]) to assert. Timeout and fail after 10us.

Type-C Hot Plug Detection (HPD)

Type-C ports have separate hot plug detection paths for thunderbolt, DP alternate, and legacy HDMI or DP connectors (static/fixed/legacy/native connection).

The HPD control and status reside in 3 separate sets of display registers

1. Thunderbolt HPD is in the north display hotplug control and interrupt registers, TBT instances.
2. DP alternate HPD is in the north display hotplug control and interrupt registers, TC instances.
3. Legacy HDMI or DP hotplug is detected through the south display hotplug control and interrupt registers.

Display software enables HPD detection in all 3 sets, then responds to whichever interrupt is received. Based on the hotplug source, display software invokes one of the connect/disconnect flows below.

The DFLEXDPSP Live State fields provide the current connect or disconnect status for thunderbolt and DP alternate.

See the Hot Plug Detection page for details.

DP Tunneling - Integrated TBT behavior

On TBT integrated products, DP resource allocation is done by IOM. A USB-C port can connect to TBT discrete device (via a cable) and then a DP source will be allocated to a TBT host to be driven according to TBT protocol. DP resources are allocated according to the IOM "DP_RESOURCE_MNG" register. TBT CM (connection manager) will claim a DP resource via this register.

When IOM claim a resource to itself, TBT connection manager interprets that that corresponding resource is allocated and TBT cannot use it. IOM can also claim a resource even when TBT already claimed the same DP resource, which will resolve in TBT releasing it in favor of IOM.

HPD Processing

HPD messages from TBT to IOM is sent via a HW mechanism. IOM requires TBT to send HPD messages only when a DP resource is allocated to it. TBT CM will build a DP tunneling path only after it gets a resource. At HPD disconnect, TBT CM will tear down the DP connection path (no tunnel) and DP AUX should also be considered as disconnected. TBT will ignore all interface signals to display engine when there is no tunnel. IOM sends acknowledgement to TBT upon receiving HPD disconnect message.

If HPD connect event is detected while TBT port is enabled for DP tunneling a mode set disable is recommended, followed by re-evaluation and re-enabling of the TBT DP tunnel.

DP Connected Standby

DP connected standby is a low power mode in which monitors will be turned OFF actively by IOM (monitors are still physically connected).

NOTE: Registers mentioned below are within Type-C subsystem and not accessible to display software.

Entering connected standby mode

IOM will assert "dp_disconnect_req" on the DP_CONFIG register.

TBT LC (link controller) will detect the above bit assertion and will configure unplug to DP adaptor.

TBT CM will receive the un-plug packet and trigger the basic disconnect flow.

Exiting connected standby mode

IOM will de-assert "dp_disconnect_req" on the DP_CONFIG register.

LC will detect the above bit de-assertion and configure the plug of the DP adapter.

CM triggers the basic connect flow.

TBT DP Path Topology Retention

TBT can route any of its DP inputs to any of its endpoint monitors. In order to keep consistency of resources routing when entering/exiting standby modes, CM will register the routing configuration on its always ON memory. Registering the DP routing configuration should be done whenever a new path is built and CM will always check last state configuration prior to claiming a DP resource.

Whenever the TBT CM detects new plug-in monitor on one of its TBT ports it follows below flow.

- TBT CM will check it's always ON memory for the last DP allocation of the new plug-in TBT port.
- TBT CM will check if DP resource is available and claim it, Otherwise claim for other DP resource. It is intended to restore to the state before entering a standby mode. IOM on its side should prevent DP ALT mode allocation to a source that was previously allocated to TBT.
- If monitors connectivity was physically changed between entering and exiting standby mode, TBT resource routing will not guarantee any sort of compatibility to pre-standby mode.
- If a new DP resource is allocated to TBT port, TBT CM should update the configuration on its always ON memory.

Connect Flows

These flows are used for completing a connection. They can be initiated upon receiving HPD connect interrupt or finding that a previous HPD connect was missed because of reset or power state. IOM FW will configure FIA and send the HPD assert message to display engine to trigger an interrupt. Display software can then complete the handshake and enable the port.

Note that display software can abort the connect flow if it does not intend to use the port main link or Aux channel. By aborting the connect, display software allows IOM to immediately change ownership of the port on a disconnect, without waiting for any display software response.

Display software is required to abort the connect if it knows it will be entering states where hotplug cannot be responded to for a long period, such as when GOP/VBIOS chooses not to enable a display on typeC, entering DC9, D3, S3, S4, and S5, and un-installing driver. Software can start the connect flow after exiting these states.

TCCOLD

The typeC subsystem can enter the TCCOLD power saving state when the state has been enabled by BIOS, there is no DP alternate or thunderbolt connection, and display software has not blocked it with a GT Driver Mailbox command. TCCOLD must be blocked by IOM or display software when display software accesses FIA or typeC PHY registers or uses Aux channel or the main link.

The general usage is for display software to use GT Driver mailbox to block TCCOLD before first accessing FIA registers during the hotplug and connect flows, then use GT Driver mailbox to unblock TCCOLD only after it is done accessing FIA registers and there is no longer a connection (connect abort complete or disconnect complete).

DP-alternate specific usage

Display software uses GT Driver mailbox to block TCCOLD before accessing FIA registers to during type-C hotplug detection.

If there is no longer a connection, display software uses GT Driver mailbox to unblock TCCOLD after finishing accessing FIA registers, and does not follow any connect flow.

If there is a DP-alternate connection, display software proceeds to the connect flow for DP alternate and leaves the mailbox in the TCCOLD blocking state.

Display software uses GT Driver mailbox to unblock TCCOLD after last accessing FIA registers when aborting the connect flow or completing the disconnect flow.

IOM will be doubly blocking TCCOLD while there is a receiver connected or once DFLEXDPPMS.DPPMSTC and DFLEXDPCSSS.DPPMSTC are both 1 in the connect flow until DFLEXDPCSSS.DPPMSTC is cleared in the disconnect flow, but display software will not rely on that.

Thunderbolt specific usage

Display software uses GT Driver mailbox to block TCCOLD before accessing FIA registers to find if a thunderbolt receiver is connected.

If there is no longer a connection, display software uses GT Driver mailbox to unblock TCCOLD after finishing accessing FIA registers, and does not follow any connect flow.

If there is a thunderbolt connection, display software proceeds to the connect flow for thunderbolt and leaves the mailbox in the TCCOLD blocking state.

Display software uses GT Driver mailbox to unblock TCCOLD when aborting the connect flow or completing the disconnect flow.

IOM and the thunderbolt controller will be doubly blocking TCCOLD while there is a receiver connected, but display software will not rely on that.

Static/fixed/legacy/native specific usage

Display software uses GT Driver mailbox to block TCCOLD before accessing FIA registers during the connect flow and leaves the mailbox in the TCCOLD blocking state.

Display software uses GT Driver mailbox to unblock TCCOLD after last accessing FIA registers when aborting the connect flow or completing the disconnect flow.

IOM is not aware of connection and will not be doing any TCCOLD blocking of its own.

GT Driver Mailbox to Block TCCOLD

This mailbox command triggers TCCOLD to exit and not re-enter.

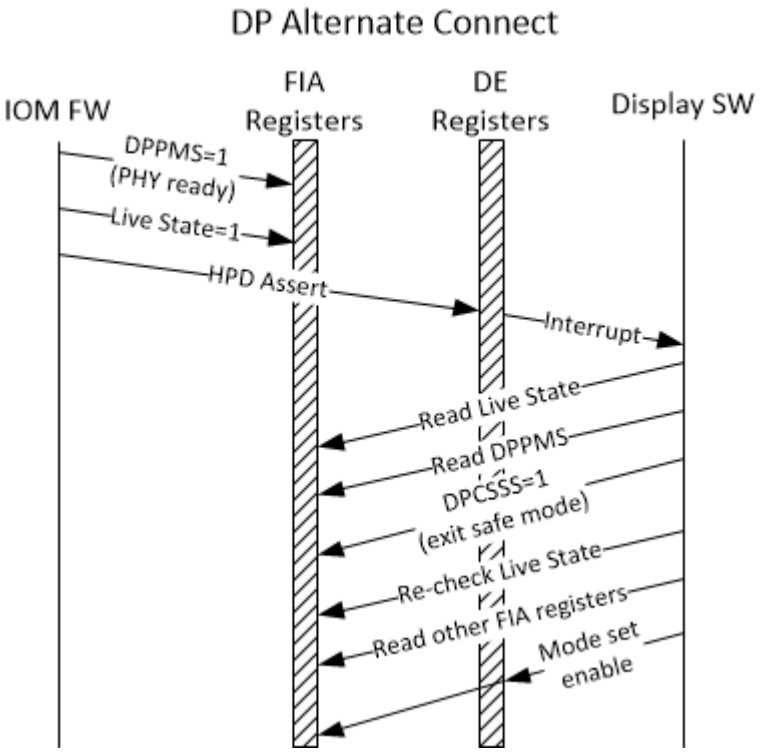
1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data Low = 0x00000000.
3. Write GT Driver Mailbox Data High = 0x00000000.
4. Write GT Driver Mailbox Interface = 0x80000026.
5. Poll GT Driver Mailbox Interface for Run/Busy indication cleared (bit 31 == 0).
    - Timeout and fail after 200 us. Do not use typeC ports if there is a timeout.
6. Read GT Driver Mailbox Data Low, if bit 0 is 0x0, continue, else go to step 2.
    - If the condition in step 6 is not satisfied after cycling through steps 2-6 for 600us total (typically <150 us), timeout and fail and do not use typeC ports.
    - Data 0 = not in TCCOLD. Data 1 = in TCCOLD.

GT Driver Mailbox to Unblock TCCOLD

This mailbox command allows TCCOLD to re-enter.

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data Low = 0x00000001.
3. Write GT Driver Mailbox Data High = 0x00000000.
4. Write GT Driver Mailbox Interface = 0x80000026.
5. Poll GT Driver Mailbox Interface for Run/Busy indication cleared (bit 31 == 0).
    - Timeout and fail after 200 us. Do not use typeC ports if there is a timeout.

Connect Flow for DP Alternate



This flow is for DP alternate mode. PHY lane 0, lane 1, or both, will be used, depending on pin assignment.

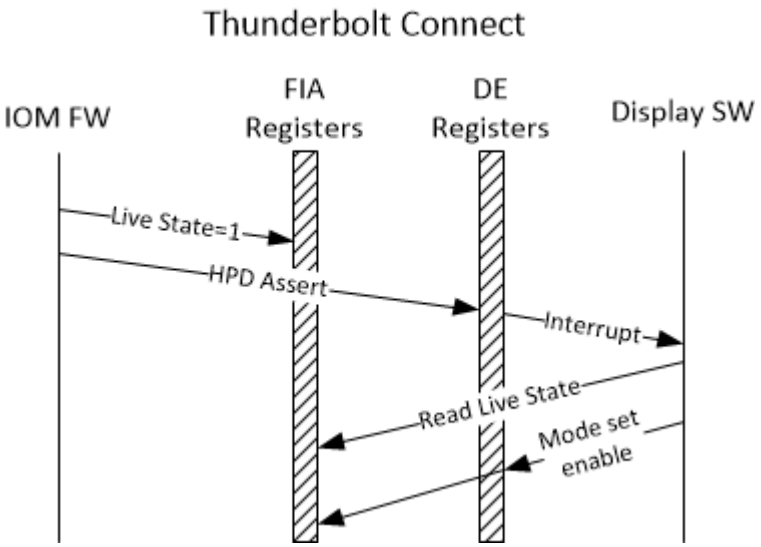
1. If display software will not use the port main link or Aux channel
    1. Abort remainder of the flow
2. Else
    1. Display software uses GT driver mailbox to block TCCOLD
    2. Display software reads DFLEXDPPMS.DPPMSTC which should be '1' to indicate the SOC uC has switched the Lane into DP Mode, else abort connect flow.
    3. Display software sets DFLEXDPCSSS.DPPMSTC to '1' indicating that display controller is not in safe mode anymore.
    4. Display software reads DFLEXDPSP to verify port has not become disconnected
        - If Live State is "No HPD Connect for TypeC or TBT", nothing is connected, so abort the connect flow.
        - If Live State is "HPD Connect for TBT", clear DFLEXDPCSSS.DPPMSTC to '0' and go to the Thunderbolt connect flow.
        - If Live State is "HPD Connect for TypeC", proceed with DP Alternate connect flow.
    5. Display software reads lane assignment from DFLEXDPSP.DPX4TXLATC register.
    6. Display software issues AUX reads for EDID/DPCD.
        - Set DDI_AUX_CTL IO Select field to legacy

- AUX power is controlled through PWR_WELL_CTL_AUX non-Thunderbolt IO Power Request
- See Type-C Aux Power Requirements for main link usage

7. Based on DFLEXDPSP.DPX4TXLATC and info from DPCD/EDID, display software knows the maximum number of lanes supported.
8. If software and the OS decide to enable display output on this connected port, software performs the DP mode set enable sequence to bring display controller up and running.

- If connect flow is aborted at any point, clear DFLEXDPCSSS.DPPMSTC to '0' if it had been set, then use GT driver mailbox to unblock TCCOLD.

Connect Flow for Thunderbolt



This flow is for DP tunneling through thunderbolt. The thunderbolt controller will configure the PHY.

1. If display software will not use the port main link or Aux channel
    1. Abort remainder of the flow
2. Else
    1. Display software uses GT driver mailbox to block TCCOLD
    2. Display software issues AUX reads for EDID/DPCD.
        - Set DDI_AUX_CTL IO Select field to TBT
        - AUX power is controlled through PWR_WELL_CTL_AUX TBT IO Power Request
        - See type-C aux power requirements for main link usage
    3. Based on info from DPCD/EDID, display software knows the maximum number of lanes supported.
    4. If software and the OS decide to enable display output on this connected port, software performs the DP mode set enable sequence to bring display controller up and running.

- If connect flow is aborted at any point, use GT driver mailbox to unblock TCCOLD.

Connect Flow for Static/Fixed/Legacy/Native

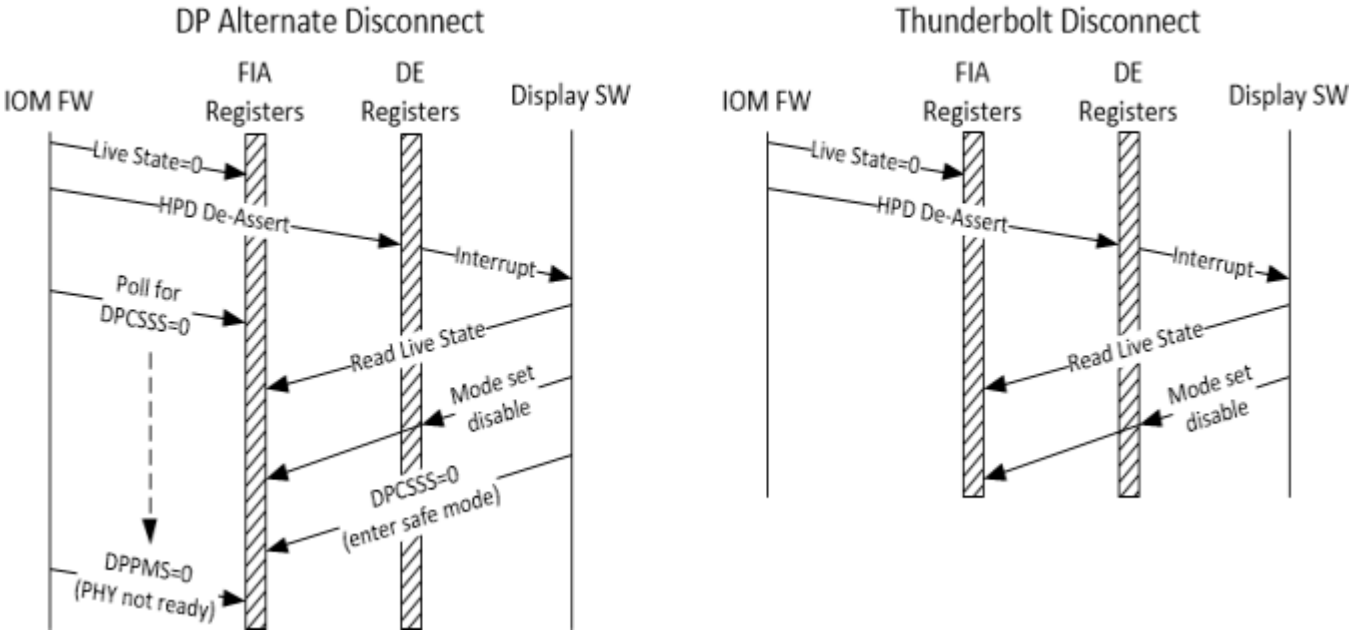
This flow is for DP/HDMI as dedicated connection. PHY lane 0 and lane 1 are dedicated to this connection.

Note: IOM is not processing static/fixed/legacy/native connections, but the handshake with FIA DFLEX registers should be followed for consistency with DP alternate mode flow.

1. If display software will not use the port main link or Aux channel
    1. Abort remainder of the flow
2. Else
    1. Display software uses GT driver mailbox to block TCCOLD
    2. Display software reads DFLEXDPPMS.DPPMSTC which should be '1' to indicate the SOC uC has switched the Lane into DP Mode, else abort connect flow.
    3. Display software sets DFLEXDPCSSS.DPPMSTC to '1' indicating that display controller is not in safe mode anymore.
    4. Set PWR_WELL_CTL_AUX non-Thunderbolt IO Power Request.
    5. Poll for PWR_WELL_CTL_AUX non-Thunderbolt IO Power State == Enabled, timeout and fail after 1.5 milliseconds (typically takes <150us).
    6. Display software issues AUX reads for EDID/DPCD.
        - Set DDI_AUX_CTL IO Select field to legacy for DP. Don't care for HDMI.
        - See Type-C Aux Power Requirements for main link usage, even for HDMI.
    7. Based on info from DPCD/EDID, display software knows the maximum number of lanes supported for DP case. For HDMI, it is always 4 lanes.
    8. If software and the OS decide to enable display output on this connected port, software performs the DP or HDMI mode set enable sequence to bring display controller up and running.

- If connect flow is aborted at any point, clear DFLEXDPCSSS.DPPMSTC to '0' if it had been set, then use GT driver mailbox to unblock TCCOLD.

Disconnect Flow



This flows is used for completing a disconnection. This can be initiated upon receiving HPD disconnect interrupt, finding that a HPD disconnect was missed because of reset or power state, or for an early disconnect where software decides it will no longer require the port main link or Aux channel until the next connect flow or power state exit.

By giving an early disconnect, display software allows IOM to immediately change ownership of the port on a real disconnect, without waiting for any display software response.

Display software is required to give an early disconnect if it knows it will be entering states where hotplug cannot be responded to for a long period, such as DC9, D3, S3, S4, S5, and un-installing driver. Software can start the connect flow after exiting these states.

1. Display software follows the mode set disable sequence. This can be done prior to disconnect flow and skipped if there was never a mode set enable.
2. Disable software disables Aux power and waits for Aux power state to disable. This cannot be done prior to mode set disable sequence because Aux power is required while Aux channel or main link are in use. Do not change the Aux control IO select field until the connect flow.
3. If not thunderbolt, display software clears DFLEXDPCSSS.DPPMSTC to '0' to tell PD FW that it had put the display Controller into Safe State.
    - Note that thunderbolt has no DFLEXDPCSSS.DPPMSTC handshake, so it is possible to receive a HPD connect interrupt before this disconnect flow is finished. Display software needs to complete the disconnect flow before moving to connect flow.
4. Display software uses GT driver mailbox to unlock TCCOLD

Link Training

- In Type-C, the connection defines the mode. Hence link training in Type-C is bound by pin assignment.
- It is ok for display engine to use fewer lanes than are available, same as if it were not a Type C connection.
- Display software is responsible for shutting off assigned but unused PHY lane(s) through DFLEXDPMLE.DPMLETC* as described in the mode set section.

Lane Configuration

Lane configuration in the case of Type-C connector (including non Type-C use cases) involves programming DE, FIA, and PHY registers. The programming is described in the mode set sequences and DDI Buffer sections.

IOM handles FIA and PHY register programming for lane configuration, except for shutting off unused lanes.

Lane reversal

Lane reversal is part of the service handled by the FIA, but only when using a type C connector.

With a legacy DP or HDMI connector, reversal is handled via the display engine DDI_BUF_CTL as selected by VBT i.e., it's a boot time configuration which will be done by display software. FIA is agnostic to any lane reversal occuring within the display controller.

Port clock programming

For DP alternate and static/fixed/legacy/native connections, a PLL in the PHY is used. For thunderbolt, a DPLL is used. The programming is described in the port clock programming section.

DDI Buffer specific registers

PHY registers are programmed to control voltage swing. The programming is described in the mode set sequences and DDI Buffer sections.

Pin Assignments

The following are the various FIA supported pin assignments, coming from the type-C specification. This shows the mapping of display data lanes through FIA to the PHY and the receiver, and the cases that limit display to 2 lanes because of using USB on the other lanes.

Please note that DE may use fewer lanes than are available, same as if it were not a Type-C connection.

Dekel PHY Register Access

Addressing Method

Each type-C port PHY is addressed through a 4KB aperture. Each PHY has more than 4KB of register space, so a separate index is programmed in HIP_INDEX_REG0 or HIP_INDEX_REG1, based on the port number, to set the upper 2 address bits that point the 4KB window into the full PHY register space.

Here is a programming example :

1. Assume Type C PHY #1 is allocated 16_8000-16_8FFFh.
2. Assume the Driver wants to write a Phy register 0x1234h.
3. Driver writes at (GTTMMADR+ HIP_INDEX_REG0[3:0] HIP_168_Index) = 01h
4. Driver writes at (GTTMMADR+16_8234h).
    - The write is forwarded to PHY #1 address [15:0] = 1234h

Note: Ignore any address defined within the PHY register. That is incorrect because the index is not accounted for.

PHY Base Addresses and Associated Index

Port #	PHY Base	Index Register and Field
5	0x16C000	HIP_INDEX_REG1 HIP_16C_Index
6	0x16D000	HIP_INDEX_REG1 HIP_16D_Index

DDI AUX Channel

DDI_AUX_CTL

DDI_AUX_DATA

AUX IO Power

Each DisplayPort Aux channel has an Aux IO Power Request. If an Aux channel will not be used, it does not need to be powered up.

PSR spontaneously sends Aux transactions. If PSR is enabled on a port, then the associated Aux IO must be kept powered up.

For Type-C, Aux IO power use has extra requirements. Refer to Type-C Aux power requirements section under Type-C programming page.

AUX IO Power Enabling

1. For combo PHY (non-typeC PHY) Aux channel, the PHY must be initialized.
2. Set **PWR_WELL_CTL_AUX** Aux IO Power Request to 1b.
    - There are two sets of PWR_WELL_CTL_AUX registers for software use. It is expected that BIOS uses PWR_WELL_CTL_AUX1 and driver uses PWR_WELL_CTL_AUX2.
3. Poll for **PWR_WELL_CTL_AUX** Aux IO Power State = 1b.
    - Timeout and fail after 10 us.

AUX IO Power Disabling

1. Clear **PWR_WELL_CTL_AUX**Aux IO Power Request to 0b.

Wait for 10us. Do not poll for the power well to disable. Other clients may be keeping it enabled.

Type-C PHY Microcontroller Health

For every typeC port (static/fixed/legacy/native and DP-alternate, but not thunderbolt), after enabling aux power request and receiving aux power ack, wait for uc_health bit (Dekel PHY register DKL_CMN_UC_DW27 @BASE + 0x236c bit [15]) to assert. Timeout and fail after 10us.

AUX programming sequence

A general purpose AUX functional programming sequence is provided below.

AUX Functional Sequence

Step	Description	Register	Notes
1	Display must already be initialized.		Power well1 enabled cdclk enabled
1a	Aux power enabled		IO powered up as needed for Aux on this project
1b	Power well containing Aux logic powered up	PWR_WELL_CTL	High level power well partitioning shown in display overview diagram
2	Disable PSR1/SRD, PSR2 and GTC if they are enabled on this DDI. Disable DC5 and DC6.	DC_STATE_EN	Power wells will disable automatically for DC5 or DC6. PSR and GTC use Aux spontaneously.
3	Program AUX data registers.	DDI_AUX_DATA_*_[0-4]	
4	Program control to configure AUX and START transaction.	DDI_AUX_CTL_*	Timeout timer value must be at least 600us. To accommodate LT-tunable PHY Repeater AUX delay, AUX Reply Timeout must be programmed to the maximum value. Timer values: 0: 400 us 1: 600 us 2: 800 us 3: 4000 us START trigger: DDI_AUX_CTL_*[31]='1'
5	Wait for AUX transaction complete.		AUX Transaction complete interrupt if set OR when DDI_AUX_CTL_*[31:30] = '01'.
6	Check that receive data has no errors	DDI_AUX_CTL_*[25]	If set: write a '1' to clear this bit and skip reading AUX data registers.
7	Read AUX data register	DDI_AUX_DATA_*_[0-4]	Condition: Aux Channel Control Register Send/Busy bit is NOT asserted
8	Clear status flags	DDI_AUX_CTL_*[30]	Transaction done status

There is a field in DDI_AUX_CTL that must be programmed for the type C ports to select if the Aux transaction will go to thunderbolt

DDI FEC

Reed-Solomon code Forward Error Correction (FEC) function RS (254, 250), with a symbol size of 10 bits is capable of correcting up to two RS symbol errors per FEC block. Display controller when plugged to an FEC-capable DPRX and anticipates enabling FEC encoding sets the FEC_READY bit in the FEC_CONFIGURATION register (DPCD Address 00120h, bit 0) to 1 before initiating link training. Display controller needs to ensure completion of link training before starting FEC encoding. After link training is

complete, display controller, if it needs to enable FEC encoding, shall send an FEC_DECODE_EN sequence to indicate the start of FEC encoding. This prompts DPRX to enable FEC decoding.

When DSC is enabled, FEC shall also be enabled.

DP Support of FEC

DP Support
FEC is supported with DP SST and MST transport modes at all lane widths.

eDP Support of FEC

eDP Support	FEC without PSR	FEC with PSR1	FEC with PSR2
FEC is supported with eDP and all lane widths. PSR restrictions apply.	Yes	Yes	**No**

GTC Target Frequency Selection

For GTC top level logic, CDCLK is taken as an input and scaled to a "target frequency" which has a period which is an exact multiple of 0.5ns. This period is also known as the accumulator increment.

Once a target frequency + accumulator increment is selected, an M and N value can be picked and fine tuned to achieve the scaling from CDCLK to target frequency.

In order for the accumulated GTC Live value to match exactly with the real passage of time, the following must be true:

The target frequency selected must be the CLOSEST possible selection to CDCLK. This corresponds to rounding the accumulator increment to the NEAREST 0.5ns increment with respect to the period of CDCLK.

Example

	Frequency	Period
Given CDCLK	337.500 MHz	2.96 ns
1st closest target frequency/increment	333.333 MHz	3.00 ns
2nd closest target frequency/increment	400.000 MHz	2.50 ns
3rd closest target frequency/increment	285.714 MHz	3.50 ns
4th closest target frequency/increment	500.000 MHz	2.00 ns

Only using the 1st closest target frequency 333.333MHz / accumulator increment of 3.00 ns will result in the GTC Live Value correctly tracking the real passage of time.

Example Calculation Flow:

1. Find the period of CDCLK -- for 337.5 MHz = 2.96 ns.
2. Round to the nearest 0.5 ns -- 3.00 ns (this is your accumulator increment value).
3. Find the "target frequency" from the rounded period value of step 2 -- 333.333 MHz is the "target frequency".
4. Find the ratio of target frequency / CDCLK = 0.987654321.
5. Choose M and N to satisfy M / N = same ratio as step 4.

If the results are not within the 1% error tolerance, multiply the accumulator increment used by 2 (i.e., use 1/2 of the target frequency). Re-select M and N as necessary to achieve the new target frequency as shown in the example below.

Example

	Frequency	Period	with 2x accumulator increment	New Period
Given CDCLK	652.800 MHz	1.531 ns		
1st closest target frequency/increment	500.000 MHz	1.500 ns	3.000ns	333.333 MHz

Example Calculation Flow:

1. Find the period of CDCLK -- for 652.800 MHz = 1.531 ns.
2. Round to the nearest 0.5 ns -- 1.500 ns
3. Multiply the above increment by 2 (this 3.00ns is your accumulator increment value).
4. Find the "target frequency" from the rounded period value of step 3 -- 333.333 MHz is the "target frequency".
5. Find the ratio of target frequency / CDCLK = 333.333 MHz / 652.800 MHz = 0.51062.

Choose M and N to satisfy M / N = same ratio as step 5.

Display Watermark Programming

Watermark Overview

The display watermarks are used to control the display engine memory request behavior.

Description
The default settings of the watermark configuration registers will **not** allow the display engine to operate. The watermark values must be properly calculated and programmed in order to enable a display and achieve optimum power and performance. Incorrectly programmed watermark values can result in screen corruption.

The watermarks should be calculated and programmed when any of the watermark calculation inputs change. This includes planes enabling or disabling, plane source format or size changing, etc.

Besides programming the watermark registers, there are other display configuration requirements and registers that must be programmed in order for the display to operate in a low power mode, and there are memory controller configuration requirements which are not documented here.

Watermark Calculations

The display watermarks are calculated using information from the display configuration and memory latencies. The watermarks must be calculated and programmed before enabling a plane or changing a plane configuration.

YUV 420 planar surface format	Plane source bytes per pixel
NV12	1 Bpp for Y surface and 2 Bpp for UV surface. Watermark values must be calculated and programmed for Y and UV surfaces separately in their watermark registers.
P0xx	2 Bpp for Y surface and 4 Bpp for UV surface. Watermark values must be calculated and programmed for Y and UV surfaces separately in their watermark registers.

The ceiling function rounds any non-integer value up to the next greater integer. Example: ceiling[0.3]=1, ceiling[2.1]=3, ceiling[4.8]=5, ceiling[4]=4

Resolutions Requiring Combined Pipes

For resolutions requiring 2 or more pipes to be joined together inside display engine, each pipe processes only 1/<# of joined pipes> of the image. The pixel rate and horizontal total pixels seen by each pipe is 1/<# of joined pipes> of that for the full resolution of the panel.

The excess pixels added for scaling smoothly across the seam between pipes do not impact the watermark.

For example: 7680x4320 CVT1.2 RB1 pixel rate is 2089.75 MHz with horizontal total 7840. That is split across 2 pipes, so each pipe is 3840x4320 with a pixel rate of 1044.875 MHz and horizontal total 3920.

Watermark Algorithm

1. Retrieve memory latency values
    - See the Memory Values section to find the memory latency values
    - The memory values do not change after boot, so software may cache them to avoid re-reading
2. For each enabled pipe (run each time pipe configuration changes)
    A. Calculate adjusted pipe pixel rate
        I. Adjusted pipe pixel rate = pixel rate for the screen resolution
            - If there will be dynamic switching between refresh rates, either use the fastest pixel rate, or re-calculate using the current pixel rate when the refresh rate is switched. Because Plane watermark registers and Link M/N registers have different double buffer update points, software will have to program both at the beginning of vactive. Alternatively, when switching from a low to high refresh rate, program the WM values first and when switching from a high to low refresh rate program the Link M/N values first. This second approach can result in a one frame delay in the refresh rate switch.
            - If plane 90 or 270 rotation is enabled, use the rotated width and height in pixel rate calculations.
        II. If TRANS_CONF Interlaced Mode == PF-ID, adjusted pipe pixel rate = adjusted pipe pixel rate * 2
        III. If pipe scaling enabled, adjusted pipe pixel rate = adjusted pipe pixel rate * pipe down scale amount
            - See the Scaling section to find the down scale amount
    B. Program WM_LINETIME Line Time = roundup[8 * pipe horizontal total pixels / adjusted pipe pixel rate MHz]
3. For each enabled plane (run each time pipe or plane configuration changes)
    A. Calculate adjusted plane pixel rate
        I. Adjusted plane pixel rate = adjusted pipe pixel rate
        II. If plane scaling enabled, adjusted plane pixel rate = adjusted plane pixel rate * plane down scale amount
            - See the Scaling section to find the down scale amount
    B. For each valid memory latency level

Plane Bytes per pixel	Minimum Scanlines for Y Tile	
	0/180 Rotation	90/270 Rotation
1	4	16
2	4	8
4	4	4
8	4	N/A

Plane Memory format	DBuf block size
8 bits per pixel surface format + Yf tiling	256
All other tiling and surface formats	512

I. Calculate method 1
   - Method 1 = (memory latency microseconds * adjusted plane pixel rate MHz * plane source bytes per pixel / DBuf block size) +1

II. Calculate method 2
   - plane bytes per line = plane source width pixels * plane source bytes per pixel
   - Calculate plane blocks per line
     - If plane memory format is Linear
       - plane blocks per line = ceiling[plane bytes per line / DBuf block size] + 1
     - Else If plane memory format is Y tile
       - plane blocks per line = ceiling[(Minimum Scanlines for Y tile * plane bytes per line/ DBuf block size)+1]/Minimum Scanlines for Y tile
     - Else
       - plane blocks per line = ceiling[plane bytes per line / DBuf block size] + 1
   - Method 2 = ceiling[(memory latency microseconds * adjusted plane pixel rate MHz) / Pipe horizontal total number of pixels] * plane blocks per line

III. Calculate Y tile minimum
   - Y tile minimum = Minimum Scanlines for Y tile * plane blocks per line

IV. Select the watermark result
   - line time microseconds = pipe horizontal total pixels/adjusted plane pixel rate MHz
   - If plane memory format is X tile or linear
     - If (((plane source bytes per pixel * pipe horizontal total number of pixels) / DBuf block size) < 1) AND ((plane bytes per line / DBuf block size) < 1) // Special case for unrealistically small horizontal total
       - Selected Result Blocks = Method 2
     - Else If ('plane buffer allocation' is known and (plane buffer allocation / plane blocks per line) >=1)
       - Selected Result Blocks = Method 2
     - Else If (memory latency microseconds >= line time microseconds)
       - Selected Result Blocks = Method 2
     - Else
       - Selected Result Blocks = Method 1
   - Else // Y tile

- Selected Result Blocks = maximum[Method 2, Y tile minimum]
- If Pipe YUV420 Bypass // PIPE_MISC YUV420 Enable == Enable and YUV420 Mode == Bypass
  - Selected Result Blocks = maximum[Selected Result Blocks, plane blocks per line] // Minimum is 1 line when using pipe YUV420 bypass

V. Convert result to blocks and lines
- Result Blocks = ceiling[Selected Result Blocks] + 1
- Result Lines = ceiling[Selected Result Blocks / plane blocks per line]
- If Y Tiling

  If 'Result Lines' is multiple of 'Minimum Scanlines for Y tile'

  Extra Lines = Minimum Scanlines for Y tile

  Else

  Extra Lines = (Minimum Scanlines for Y tile * 2) - (Result Lines % Minimum Scanlines for Y tile)

  Minimum Display Buffer allocation Needed = ceiling[(Result Lines + Extra Lines) * plane blocks per line]

  Else

  Minimum Display Buffer allocation Needed = ceiling[Result Blocks + (Result Blocks * 0.1)]

VI. Compare against the maximum
- If (Result Blocks >= plane buffer allocation), maximum exceeded for this latency level
- Maximum Lines: 31
- If (Result Lines > Maximum Lines), maximum exceeded for this latency level
- If (Minimum Display Buffer allocation Needed >= plane buffer allocation), maximum exceeded for this latency level
- or YUV 420 Planar formats, perform the above check for both Y and UV planes.

4. For each transition watermark
   - This includes<PLANE,CUR>_WM_TRANS, which is calculated relative to memory latency level 0.

A. Calculate transition offset
   - Transition Offset Blocks = Transition minimum + Transition amount
   - See Transition Watermark section for transition minimum and transition amount

B. Calculate transition Y tile minimum
   - Transition Y tile minimum = 2 * relative memory latency level Y tiled minimum

C. Select the watermark result
   - If plane memory format is X tile or linear

- Result Blocks = Relative memory latency level Selected Result Blocks + Transition Offset Blocks
- Else // Y tile
  - Result Blocks = maximum[Relative memory latency level Selected Result Blocks, Transition Y tile minimum] + Transition Offset Blocks

D. Convert result to blocks
- Result Blocks = ceiling[Result Blocks] + 1

E. Compare against the maximum
- If (Result Blocks >= plane buffer allocation), maximum exceeded for transition watermark
- For YUV 420 Planar formats, perform the above check for both Y and UV planes.

5. Program watermark registers

A. For each latency level
- If memory latency for this level is invalid, or the maximum was exceeded for this level or any previous level, program PLANE_WM_<latency level> Enable = 0
  - **If watermark latency level 0 exceeds the maximum, the plane must not be enabled.**
- Else program PLANE_WM_<latency level> Enable = 1, Lines = Result Lines, Blocks = Result Blocks

B. For transition watermarks
- If the maximum was exceeded for the transition watermark, program the transition watermark register Enable = 0
- Else program the transition watermark register Enable = 1, Blocks = Transition Result Blocks
  - The transition watermark Lines value is ignored by hardware

C. Write the plane surface base address register to trigger update of the watermarks and other plane double buffered registers. This should be done only after all plane configuration is configured to match the new watermark values.

Transition Watermark

The transition watermark is used for Isochronous Priority Control (IPC). When IPC is enabled, plane read requests are sent at high priority until filling above the transition watermark, then the requests are sent at lower priority until dropping below the level 0 watermark. The lower priority requests allow other memory clients to have better memory access. If the transition watermark is not enabled, the plane behaves as if the transition watermark was programmed to the top of the plane buffer allocation. When IPC is disabled, all plane read requests are sent at high priority. It is allowed for one of a pair of planes supporting YUV420 together to have transition watermark disabled while the other plane has it enabled.

The transition watermark is programmed as a tunable amount above the relative memory latency level watermark. Tuning to higher values will tend to cause longer periods of high priority reads followed by

longer periods of lower priority reads. Tuning to lower values will tend to cause shorter periods of high and lower priority reads. The exact behavior depends on the memory bandwidth, display bandwidth, and other memory traffic in the system.

The transition watermark has a minimum value to ensure the demote does not happen before enough data has been read to meet the relative memory latency level watermark requirements.

Transition Minimum: 4 Blocks

IPC Enable Register Field
ARB_CTL2 Enable IPC

Scaling

A scaler (pipe or plane scaler) is down scaling when it is enabled and the scaler input size is greater than the scaler output size.

Down scaling effectively increases the pixel rate. Up scaling does not reduce the pixel rate.

For plane scaling, the scaler input size is the plane size and the output size is the scaler window size.

For pipe scaling, the scaler input size is the pipe source size and the output size is the scaler window size.

Horizontal down scale amount = maximum[1, Horizontal source size / Horizontal destination size]

Vertical down scale amount = maximum[1, Vertical source size / Vertical destination size]

Total down scale amount = Horizontal down scale amount * Vertical down scale amount

System Agent Geyserville (SAGV) Interaction with Watermarks

SAGV dynamically adjusts the system agent voltage and clock frequencies depending on power and performance requirements. The display engine access to system memory is blocked outside of display engine, without a PM handshake, during the adjustment time.

To compensate for the block, display engine must increase the latency for watermark level 0 by the SAGV block time. If there is not enough data buffer to support that increase, then software must disable SAGV. Other watermark levels do not need increase because after a package C exit SAGV will not run until after display has refilled above watermark level 0.

SAGV defaults to enabled.

See the Memory Values section to find the SAGV block time.

The latency input to the watermark calculation for each level must be greater than or equal to the lower level. The latency increase to level 0 for SAGV requires the upper levels to be adjusted to meet that requirement. Use MIN(latency for this level, latency for next lower level) to correct the latency.

Requirement before plane enabling or configuration change: Calculate watermark level 0 with level 0 latency + SAGV block time. If the result can be supported (does not exceed maximum), then the plane can tolerate SAGV, so proceed with watermark calculations for level 0 using latency increased by SAGV block time.

If the plane cannot tolerate SAGV, proceed with watermark calculations for all levels using the normal latency

values.

Disable SAGV (sequence below) if any enabled plane cannot tolerate SAGV, or any transcoder is interlaced. Else, enable SAGV.

The expectation is that SAGV can be tolerated in most non-interlaced configurations and will only need to be disabled for some high resolution, multiple display scenarios.

If one plane was already enabled and able to tolerate SAGV, then a second plane becomes enabled and cannot tolerate SAGV, causing SAGV to disable, software can recalculate and reprogram the watermarks for the first plane without the SAGV block time. That reprogramming is preferred to give more optimal watermark results, but not required.

To disable SAGV, follow the SAGV section SAGV Point Selection Runtime flow to mask off all but the one QGV point that supplies the highest bandwidth for display.

To enable SAGV, follow the SAGV section SAGV Point Selection Runtime flow to unmask all of the QGV points that supply enough bandwidth for the display configuration.

Examples

Example pixel rate adjustments:

Pixel rate for screen resolution is 130 MHz. No interlacing. Pipe scale 1920x1080 pipe source size to 1714x1120 scaler window size. Plane scale 1920x1080 plane size to 800x600 scaler window size.

Pipe horizontal down scale amount = maximum[1, 1920 / 1714] = 1.12

Pipe vertical down scale amount = maximum[1, 1080 / 1120] = 1 **// Max condition was hit**

Pipe total down scale amount = 1.12 * 1 = 1.12

Adjusted pipe pixel rate = 130 MHz * 1.12 = 145.6 MHz

Plane horizontal down scale amount = maximum[1, 1920 / 800] = 2.4

Plane vertical down scale amount = maximum[1, 1080 / 600] = 1.8

Plane total down scale amount = 2.4 * 1.8 = 4.32

Adjusted plane pixel rate = 145.6 MHz * 4.32 = 628.99 MHz

Example method, block, and line calculations:

Plane source 4 Bpp, Plane X tile, Plane source width 1920 pixels, Horizontal total 2200 pixels, Adjusted plane pixel rate 148.5 MHz, memory latency 7.5 us

Method 1 = 148.5 MHz * 4 Bpp * 7.5 us / 512 = 8.7 blocks

Plane bytes per line = 1920 pixels * 4 Bpp = 7680 Bytes/line

Plane blocks per lines = ceiling[7680 / 512] = 15 blocks

Method 2 = ceiling[(7.5 us * 148.5 MHz) / 2200 pixels] * 15 blocks = 15 blocks

Y tile minimum = 4 * 15 blocks = 60 blocks

Result Blocks = minimum[8.7 blocks, 15 blocks] = 8.7 blocks // X tile so does not use Y tile minimum

Result Blocks = ceiling[8.7 blocks] + 1 block = 10 blocks

Result Lines = ceiling[8.7 blocks / 15] = 1 lines

Memory Values

Retrieve Memory Latency Data

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data0=0x0000_0000 (first set of latency values) and GT Driver Mailbox Data1=0x0000_0000
3. Write GT Driver Mailbox Interface Run/Busy=1, Address Control=All 0s, Command/Error Code=06h
4. Poll GT Driver Mailbox Interface for Run/Busy indication=0b and Command/Error Code=00h (success)
    - Timeout after 100 us and do not enable display planes.
5. Read GT Driver Mailbox Data0 for the first set of memory latency values
6. Write GT Driver Mailbox Data0=0x0000_0001 (second set of latency values) and GT Driver Mailbox Data1=0x0000_0000
7. Write GT Driver Mailbox Interface Run/Busy=1, Address Control=All 0s, Command/Error Code=06h
8. Poll GT Driver Mailbox Interface for Run/Busy indication=0b and Command/Error Code=00h (success)
    - Timeout after 100 us and do not enable display planes.
9. Read GT Driver Mailbox Data0 for the second set of memory latency values

Memory Latency Data Definition

First Set:

Data0 Bit	Name	Description
31:24	Level 3	Number of microseconds for level 3.
23:16	Level 2	Number of microseconds for level 2.
15:8	Level 1	Number of microseconds for level 1.
7:0	Level 0	Number of microseconds for level 0.

Second Set:

Data0 Bit	Name	Description
31:24	Level 7	Number of microseconds for level 7.
23:16	Level 6	Number of microseconds for level 6.
15:8	Level 5	Number of microseconds for level 5.

Data0 Bit	Name	Description
7:0	Level 4	Number of microseconds for level 4.

If level 1 or any higher level has a value of 0x00, that level and any higher levels are unused and invalid, so the associated watermark registers must not be enabled. Level 0 is always valid.

It is allowed to have the same value in adjacent levels.

Programming Note	
Context:	Display Watermark Programming
The mailbox response data may not account for memory read latency. If the mailbox response data for level 0 is 0us, add 3 microseconds to the result for each valid level. The previous requirement was 2us, but high density DIMMs have increased refresh times that requires a 1us increase.	

SAGV Block Time

The block time is retrieved from the GT driver pcode mailbox.

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data0=0x0000_0000 (first set of latency values) and GT Driver Mailbox Data1=0x0000_0000
3. Write GT Driver Mailbox Interface Run/Busy=1, Address Control=All 0s, Command/Error Code=23h
4. Poll GT Driver Mailbox Interface for Run/Busy indication=0b and Command/Error Code=00h (success)
    - Timeout after 100 us and do not enable display planes.
5. Read GT Driver Mailbox Data0 for the block time in microseconds

- The Steering Control Registers reside at the following locations:
    - MGSR access point (access initiated by agent outside of GT):

#	Steering Reg Addr	Description
1	0xFD0	Access steering towards MCFG endpoints only.
2	0xFD4	Access steering towards MDRB endpoints only
3	0xFD8	Access steering towards SF endpoints only
4	0xFDC	Access steering towards all other endpoints (all but above)

- GuC access point:

#	Steering Reg Addr	Description
1	0xC060	Access steering towards all GT endpoints

- CS access point:

#	Steering Reg Addr	Description
1	0x20CC	Access steering towards all GT endpoints

- **Note:** All Steering Control Registers contain the following fields:

Field	Description
multicast	1: Access will be multicast to all replicated endpoints: • *WRITE* op cycles go to all endpoint instances; sliceid[]/subsliceid[] fields ignored. • *READ* op cycles go to all endpoint instances, and responses are returned from all instances; The MsgCh selects single instance's response as the final read return, based on sliceid[]/subsliceid[] fields. 0: Access will be steered using sliceid[] and subsliceid[] fields below: • Both *WRITE* and *READ* cycles go to a single instance of an endpoint, based on sliceid[]/subsliceid[] steering. Default: 1 Note: The multicast field has no impact for a non-replicated target.
sliceid[]	Default: 0
subsliceid[]	Default: 0

- The following Replication Group Types exist for multicast MMIO endpoints:

Replication Group Type	Description / Notes
SQIDI	• 2 instances • subsliceid: 0..1 • all instances are always present.
DSS	• LP has max 6 DSS • subsliceid: 0..5 • Terminated/disabled when the corresponding dss_enable bit is '0'
L3BANK	• 8 instances • subsliceid 0..7 to access • Terminated/disabled when corresponding fuse_gt_l3disable bit is 'disable'

- Fuse reflections (how to tell when an endpoint is disabled):

Fuse	Register reflection
fuse_gt_dssen[5:0]	0x913C[5:0]
fuse_gt_l3_disable[3:0]	0x9118[7:0] (fuse is replicated into [3:0] and [7:4])

Note: MsgCh termination also occurs when the domains are powered down. (i.e., not necessarily because the domain is disabled/fused off.) If reading/writing the registers is needed, then force-wake of the domain is required. Force-wake is not required for shadow register accesses coming through MGSR.

- The following table captures the force-wake and corresponding acknowledgment register locations for the various domains:

Domain	Driver ForceWake Req	Driver ForceWake Ack	GuC ForceWake Req	GuC ForceWake Status	Comment
AON	NA	NA	NA	NA	Registers sit outside of the C6 boundary. No ForceWake required.
GT	0xA188	0x00130044	NA	NA	
Render	0xA278	0x0D84	0xA27C	0xA2A0[1]	
VDBOX0	0xA540	0x0D50	0xA274[0]	0xA2A0[0]	

VDBOX1	0xA544	0x0D54	0xA274[1]	0xA2A0[0]	
VDBOX2	0xA548	0x0D58	0xA274[2]	0xA2A0[2]	
VDBOX3	0xA54C	0x0D5C	0xA274[3]	0xA2A0[2]	As available in the product
VDBOX4	0xA550	0x0D60	0xA274[4]	0xA2A0[3]	As available in the product
VDBOX5	0xA554	0x0D64	0xA274[5]	0xA2A0[3]	As available in the product

VDBOX7	0xA55C	0x0D6C	0xA274[7]	0xA2A0[4]	As available in the product
VEBOX0	0xA560	0x0D70	0xA274[8]	0xA2A0[0]	As available in the product
VEBOX1	0xA564	0x0D74	0xA274[9]	0xA2A0[2]	As available in the product
VEBOX2	0xA568	0x0D78	0xA274[10]	0xA2A0[3]	As available in the product
VEBOX3	0xA56C	0x0D7C	0xA274[11]	0xA2A0[4]	As available in the product

- Miscellaneous Notes:
- The MsgCh network has termination points, where cycles to endpoints that are disabled (fused-off, powered off, etc…) are gracefully completed. The termination node on the network will sink P cycles, and return dummy completions for NP cycles, on behalf of the disabled endpoints.
- Access requirements to registers that are part of GTMMADDR but not listed in the GT MMIO map table is defined elsewhere. This descriptions in this document only cover GT range (GT MMIO map xls.)

Multicast Steering and Die Recovery

Some units in GT are replicated multiple times in the design, each with their own register storage local to that instance.

- In some cases, each replica/instance gets its own MMIO address range of offsets – for example, the multiple CCS command streamers, multiple VDBox/VEBox instances. For those, direct register access targets the only instance of that registers. The programming model described on this page is moot for those cases where each register has unique address.
- In other cases, the multiple instances of the unit use the same MMIO address on message channel. For these cases, the message channel provides additional capabilities to address the instances for read/write operations in either multicast (targeting all instances) or unicast modes (target specific instance) via a set of "steering registers" which can be configured to direct the access as desired. The steering registers have 3 fields: Multicast/Unicast, Sliceid, Subsliceid.
    - Multicast write access - write goes to all instances; sliceid/subsliceid fields are ignored
    - Multicast read access – read goes to all instances and all instances generate read response; message channel selects single instance's response as the final read return (based on the steering register slice/subslice fields)
    - Unicast write access – write goes to only the instance specified in the steering register
    - Unicast read access – read goes to only the instance specified in the steering register
    - In some replicated units, all of the replicated instances always "enabled" from a message channel perspective (never fused off/separately power gated) and thus all instances are always accessible if the containing power well is on (e.g. if GT is out of RC6)
    - In some replicated units, there are die recovery/fuse down modes where some instances are fused off/disabled. For the latter, GT also contains MMIO registers which allow SW to detect which instances are fused as enabled/disabled (generally 1-hot). When this fuse down case applies, message channel is aware of the fusing and provides automatic termination of cycles toward disabled instances (writes get dropped with dummy NP completion if NP write; reads get dummy completion with 0 read return value from that instance). The fuse mirror register provides a mechanism for SW to know which instances are valid and to program the steering register toward enabled instances when needed – see comments below.

General rules:

- Some of these replicated registers are control registers which are generally expected to be all programmed with the same value – for these, writes should generally be multicast and reads can target any enabled instance (since all instances should contain the same value from prior multicast write).

- Some replicated registers are status registers and are expected to have different values as part of normal usage (for example, INSTDONE registers related to Sampler, Slice common; TDL thread

status, etc). For these typical usage model would be to either iterate over all enabled instances or select specific single instance to target.

- If an instance is disabled (access terminated on message channel via the fuse info above or if containing power well is power gated), reads from that instance will return 0s and writes are silently dropped. Since the default for the steering registers is multicast read with sliceid=subsliceid=0, the default hardware behavior is to return data from instance that corresponds with sliceid/subsliceid = 0. If that instance is disabled, message channel will return a dummy response (0). In order to get correct/valid value the steering registers must be used to access a valid instance.
    - Note that a common usage model is for SW/FW to initializing specific bits in control register by reading the current/default value, then modifying the value in memory (set/clear few bits), and then write the result back.
    - For these cases, SW must ensure that it uses the steering registers to steer to an enabled instance when performing the initial read.
- When performing engine and power context save restore, GT hardware is aware of the fuses and internally targets reads for context save toward the first enabled instance.
- In cases where steering registers are being programmed, caution must be exercised to ensure that there is no race condition/concurrent access between two different initiators using a given steering register. SW must protect against concurrent access by multiple threads to any given steering register. System level flows must also guard against concurrent access by Firmware (CSC/FSP FW, Punit pCode) and driver tools to any given steering register.
    - Multicast is the hardware default. If an agent sets a steering register to unicast mode, they should generally set it back to multicast after completion.
    - In some projects there are separate steering registers listed are intended to allow for some degree of concurrency between different usages targeting different destinations in GT by replication group.
        - MGSR uses the MMIO offset requested in the inbound cycle to select which steering register to use for routing.
        - MGSR uses SAI policy registers to identify sources as “IA” (low privilege cfg_src on message channel) vs “HW” (high privilege – includes trusted firmware such as CSC/FSP, Pcode)
        - See project specific documentation for the list of steering registers and their intended use.

SW Virtualization Reserved MMIO range

The MMIO address range from 0x178000 thru 0x178FFF is reserved for communication between a VMM and the GPU Driver executing on a Virtual Machine.

HW does not actually implement anything within this range. Instead, in a SW Virtualized environment, if a VM driver issues a read to this MMIO address range, the VMM will trap that access, and provide whatever data it wishes to pass to the VM driver. In a non-SW-Virtualizated environment (including an SR-IOV Virtualized environment), reads will return zeros, like any other unimplemented MMIO address. Writes to this range are always ignored.

It is important that no "real" HW MMIO register be defined within this range, as it would be inaccessable in a SW-virtualized environment.

Register Address Maps

Graphics Register Address Map

This chapter provides address maps of the graphics controllers I/O and memory-mapped registers. Individual register bit field descriptions are provided in the following chapters. PCI configuration address maps and register bit descriptions are provided in the following chapter.

VGA and Extended VGA Register Map

For I/O locations, the value in the address column represents the register I/O address. For memory mapped locations, this address is an offset from the base address programmed in the MMADR register.

VGA and Extended VGA I/O and Memory Register Map

Address	Register Name (Read)	Register Name (Write)
2D Registers		
3B0h-3B3h	Reserved	Reserved
3B4h	VGA CRTC Index (CRX) (monochrome)	VGA CRTC Index (CRX) (monochrome)
3B5h	VGA CRTC Data (monochrome)	VGA CRTC Data (monochrome)
3B6h-3B9h	Reserved	Reserved
3Bah	VGA Status Register (ST01)	VGA Feature Control Register (FCR)
3BBh-3BFh	Reserved	Reserved
3C0h	VGA Attribute Controller Index (ARX)	VGA Attribute Controller Index (ARX)/ VGA Attribute Controller Data (alternating writes select ARX or write ARxx Data)
3C1h	VGA Attribute Controller Data (read ARxx data)	Reserved
3C2h	VGA Feature Read Register (ST00)	VGA Miscellaneous Output Register (MSR)

Address	Register Name (Read)	Register Name (Write)
3C3h	Reserved	Reserved

3DBh-3DFh	Reserved	Reserved

Indirect VGA and Extended VGA Register Indices

The registers listed in this section are indirectly accessed by programming an index value into the appropriate SRX, GRX, ARX, or CRX register. The index and data register address locations are listed in the previous section. Additional details concerning the indirect access mechanism are provided in the *VGA and Extended VGA Register Description* Chapter (see SRxx, GRxx, ARxx or CRxx sections).

2D Sequence Registers (3C4h / 3C5h)

Index	Sym	Description
00h	SR00	Sequencer Reset
01h	SR01	Clocking Mode
02h	SR02	Plane / Map Mask
03h	SR03	Character Font
04h	SR04	Memory Mode
07h	SR07	Horizontal Character Counter Reset

2D Graphics Controller Registers (3CEh / 3CFh)

Index	Sym	Register Name
00h	GR00	Set / Reset
01h	GR01	Enable Set / Reset
02h	GR02	Color Compare

22h	CR22	Memory Read Latch Data

GUC

GUC is part of the System Interfaces Volume.

GuC Introduction

GuC is an embedded micro-controller in the graphics sub-system that is designed to perform graphics workload scheduling on the various graphics parallel engines. In this scheduling model, host software submits work through one of the 256 graphics doorbells and this invokes the micro-kernel running on the GuC core to perform the scheduling operation on the appropriate graphics engine.

Scheduling operations include determining which workload to run next, submitting a workload to a command streamer, pre-empting existing workloads running on an engine, monitoring progress and notifying host SW when work is done. To perform these actions, the GuC requires access to a wide range of assets within the graphics subsystem. The GuC has access to the entire graphics device MMIO register space to allow it to schedule work on any graphics engine.

The code that runs on the GuC is provided by the graphics driver (KMD) during the boot-up and graphics initialization phase. Code provided by the driver is copied from graphics memory and authenticated before execution.

From a functional perspective, the GuC sub-system has the following blocks:

- A Shim block that provides an interface between the micro-controller and rest of the graphics assets.
- An interrupt block that aggregates all the notifications coming from various graphics engines and communicates them to the GuC micro-controller for action. The interrupt block supports (programmable) prioritized delivery of events.
- A DMA engine to allow efficient copy of large blocks of data between memory and internal SRAM. During GuC initialization phase, this DMA engine is available to the host SW to load the GuC micro-kernel. Once the micro-kernel is successfully loaded into GuC, the access to the DMA engine is restricted to the code running on the GuC.
- It also has additional infrastructure to receive notification that are required for scheduling (semaphores from engines, page faults/faults-cleared from Memory interface, etc)
- A GuC power management unit that determines when all the GuC components are idle and supports the power management protocol with the Power Management unit.

Once code is loaded successfully, the primary method of communication with GuC is through the workload doorbells and a GuC/host interrupt mechanism. GuC automatically saves and restores its code image across RC6 power states, so no host intervention is required during these power transitions.

Terminology

Description	Software Use	Must Be Implemented As
Read/Write, R/W	This bit can be read or written.	
Reserved	Do not assume a value for these bits. Writes have no effect.	Writes are ignored. Reads return zero.
Reserved: must be zero, MBZ	Software must always write a zero to these bits. This allows new features to be added using these bits that will be disabled when using old software and as the default case.	Writes are ignored. Reads return zero. Maybe be connected as Read/Write in future projects.
Reserved: PBC, software must preserve contents	Software must write the original value back to this bit. This allows new features to be added using these bits.	Read only or test mode Read/Write.
Read Only	This bit is read only. The read value is determined by hardware. Writes to this bit have no effect.	According to each specific bit. The bit value is determined by hardware and not affected by register writes to the actual bit.
Read/Clear, Read/Write Clear	This bit can be read. Writes to it with a one cause the bit to clear.	Hardware events cause the bit to be set and the bit is cleared on a write operation where the corresponding bit has a one for a value.
Double Buffered	Write when desired. Read gives the unbuffered value (written value) unless specified otherwise. Written values will update to take effect after a certain point. Some have a specific arming sequence where a write to another register is required before the update can take place. This is used to ensure atomic updates of several registers.	Two stages of registers used. First stage is written into and used for readback (unless specified otherwise). First stage value is transferred into second stage at the update point. Second stage value is used to control hardware. Arm/disarm flag for specific arming sequences.

Arming Doorbells

As indicated in the Workload submission section, doorbell rings signal request for work to be submitted to hardware.

Doorbells need to be configured (armed) before they can be rung. Following sections describe the sequence.

Arming Memory Based Doorbells

Doorbells (As described in the GPU doorbells section in the "Memory View" chapter) are used to submit work to the hardware. Each doorbell monitors a memory address (cacheline) that detects a write to the cacheline and generates an interrupt to the MinIA core.

A distributed doorbells infrastructure is provided. Distributed doorbell units save doorbells in parallel so there are some performance benefits if SW distributes doorbells evenly across Doorbell Units. Hence the infrastructure allows SW to explicitly pick the IDI (ring interface) on which the doorbell needs to be installed.

The memory address programmed into the doorbell register needs to be Physical address. Since addresses are hashed on IDI (physical address based hashing), this address needs to have specific attributes to land on a specific IDI. To enable this Graphics KMD picks the doorbell Page Address, GuC Shim HW computes the cacheline address within the page.

When virtualization is enabled, the memory address provided by the Graphics Kernel Mode Driver needs to be translated from Guest Physical Address(GPA) to Host Physical Address(HPA) before getting programmed into the doorbell register. To conform to the security requirements of virtualization where only Virtual Machine Manager is aware of the HPA values, the GPA --> HPA translation is automatically done by GuC Shim HW as described below. The Guc Shim computes the cacheline address based on the HPA of the doorbell page address and this is returned to the KMD so that it has a fully formed Doorbell cacheline address.

Note that the hashing algorithm is different depending on how many LLC/CBO slices are present in the part. GT receives a fuse value at manufacturing that indicates which hashing rule should be used. That fuse value is not communicated directly to GUC hardware; instead, the Graphics Kernel Mode Driver is required to copy information about the hashing mode fuse from a register in the GT perimeter (SNOOP_FILTER_Q_STATUS - offset 0xB00[30]) to the GUC shim (SHIM_CTRL_GUC0_REG - offset 0xC068[10]). Driver must do this prior to arming any doorbells. Note that this value is retained across RC6 cycles but is lost on FLR, warm/cold reset, etc. Thus driver must program this value on every driver start/load as well as after any driver initiated FLR. Stated differently, any time driver loads GUC firmware, it should also perform this B00[30]-> C068[10] copy operation.

Doorbell Arming Sequence

- The memory page address to be monitored is picked by the Graphics Kernel Mode Driver and provided to the MinIA FW.
- Graphics KMD communicates the doorbell details to MinIA FW: Doorbell memory Page-address to be monitored, IDI#, Doorbell ID

- MinIA FW computes Doorbell MMIO
- MinIA FW programs the memory address to be monitored to the doorbell range: 0x1000 - 0x17FF range.
- GuC Shim HW intercepts the Doorbell MMIO targeted cycles to provide a GPA --> HPA translation and installs the translated address into the doorbell. Using the returned HPA, HW also computes the appropriate cacheline address that is returned to the FW for propagaton back up to the KMD. Detailed HW sequence is described below.
- MinIA FW monitors register 0xC090 and 0xC094 waiting for HW to signal completion of the doorbell install step and then checks status to determine if this was completed successfully.

GuC Shim (GUCSHIM) Register Functions

The GuC Shim provides the interface between GuC and the rest of GT. It is comprised of the various status registers that communicate the current state of the GuC, the infrastructure to setup the address space for GuC operation and interface with message channel.

Context:	The following table provides a view of the GuC address space

Address Top	Address Bottom	Space	Description
0xFFFF_FFFF	0xFFE0_0000	Graphics MMIO	2 MB off the top of the 4GB space
0xFFDF_FFFF	0xFEE0_1000	Hole	
0xFEE0_0FFF	0xFEE0_0000	LAPIC	4KB that houses the Local APIC registers. The accesses to this region are redirected to the LAPIC before they get to the shim decoder.
0xFEDF_FFFF	WOPCM_TOP	DRAM - Graphics Memory	Section should be decoded as: **Upper bound:** 4GB - 2MB(Gfx mmio) - 16MB **Lower bound:** 80KB Lower bound accounts for 16KB + 64KB
WOPCM_TOP-1	0x0006_8000	DRAM - WOPCM	Write Only Protected Content Memory (WO-PCM) This allows for code to straddle SRAM and memory (as described later)
0x0006_7FFF	0x0000_8000	SRAM space	384 KB SRAM This gets loaded with the GuC micro-kernel. The GuC may also use portion of the SRAM for its data, stack, and other required components.
0x0000_7FFF	0x0000_0000	Boot ROM	32 KB of BootROM for Initialization and authentication code that the GuC first jumps to is located here.

Context:	MinuteIA L1 Cacheability

By default, the Shim uses the following rules for caching in the MinuteIA L1 cache.

- 0xFEE0_0000 - 0xFFFF_FFFF: Un-Cached (Covers the 2MB Gfx address space + 16MB hole)
- 0x0000_0000 - 0xFEDF_FFFF: Cached (Everything below)
- By default, MinIA treats all WOPCM cycles as WB while Gfx-GTT cycles are WT. If C064[16] is set, all cycles (below xFFE0_0000) from MinIA are WB.

Graphics driver can create an Un-cached region window in the lower range described above, by programming the Non_Cacheable_Region_Base and Non_Cacheable_Region_Limit registers.

When using the GuC DMA engine to load the HuC uKernel, the status can be obtained by reading:

- GuC's BOOT_HASH_CHK register (0xc010 bit 8) to see if a HuC uKernel loading had been attempted, and
- HuC's HUC_STATUS2 register (0xd3b0 bit 7) to check whether or not the HuC uKernel was successfully loaded.

GUCSHIM Registers

Register
GUC_STATUS - Global MicroController Status
JMP_DEST - Jump Location
MIA_FORCE_FENCE - Minute IA Force Fence
MIA_INV_TLB - Minute IA Force TLB Invalidate
UOS_FULL_HASH_LO - uOS Full Hash Low
UOS_FULL_HASH_HI - uOS Full Hash High
SOFT_SCRATCH - Soft Scratch
UOS_RSA_SCRATCH - RSA for uOS/Soft Scratch

Guc DMA (GUCDMA)

The DMA engine allows the MinuteIA core to move data back and forth efficiently from the various memory segments listed below. Note that the DMA engine supports more than current required usage models. Memory segments supported:

- Global GTT mapped memory
- Per Process GTT mapped memory
- WOPCM
- SRAM

The MinIA is a 32 bit engine so it cannot generate an address greater than 4 GB. Thus any data that the MinIA core has to access must be located <4 GB in the graphics address space. The graphics address generated by the MinIA core goes through the regular graphics page table walk to derive the physical address that can be above 4 GB.

The DMA engine supports the full 48 bit addressing so it can be used by the MinIA core to get to the address regions above 4 GB. The MinIA core programs this DMA engine through registers that are mapped into the Gfx MMIO.

The DMA Registers

GUCDMA uses two 64-bit registers (4 DWord registers) to indicate the 48-bit Source and Destination addresses along with fetch type indication etc. Bit 1 of the DMA Control Register (described later) pins DMA Address Register 0 to Source addressing or Destination, and vice versa for DMA Address Register 1. By default, DMA Address Register 0 is assigned to Source addressing and DMA Address Register 1 to Destination addressing.

Register
DMA_ADDR_0_LOW - DMA Address Register 0 Low
DMA_ADDR_0_HIGH - DMA Address Register 0 High
DMA_ADDR_1_LOW - DMA Address Register 1 Low
DMA_ADDR_1_HIGH - DMA Address Register 1 High
DMA_COPY_SIZE - DMA Copy Size
DMA_CFG - DMA Configuration
DMA_CTRL - DMA Control

Programming Note	
Context:	The DMA Registers

Notes:

- The DMA engine can be deactivated by setting the Disable-GuC fuse. If this fuse is set, the DMA engine is rendered inoperable, so it cannot be used to load a GuC uOS or move any data. On a product that intends to use GuC, this fuse shall be zero.
- The lower 6 bits of *addressing* of both Source and Destination addresses must be same. There is no provision for barrel rotation across byte locations, during a DMA Transfer.
- The following restrictions shall be followed for placement of uOS and uApps:
  - uOS and uApps are always located on a 64-byte aligned address.
- uApps are not automatically loaded into SRAM by HW. uKernel must explicitly copy a uApp into SRAM from WOPCM when using it.
- Once the ukernel and the uApps have been loaded successfully into the WOPCM area, the HW shall not allow DMA operation to overwrite them.
- Before programming the DMA engine to access memory in the Per Process GTT address space, GuC SW must setup the PPGTT by programming registers: These registers are located in the GUC_PM unit (offsets: 0xC3B8 - 0xC3F0):
  - CTXT_INFO
  - PDP0, PDP1, PDP2, PDP3
  - PPGTT_ENABLE
- The GuC DMA engine also provides support for loading the HuC micro-kernel. To load a third party HuC ukernel, the third party GuC ukernel must be loaded first. An authenticated GuC ukernel can then be invoked to load a HuC ukernel. (If a third party HuC ukernel is loaded first, there is no way to clear the ME_DATA registers - thus locking out the ability to load a third party GuC).
- GuC DMA HW checks for the following illegal cases and rejects the DMA invocation (DMA will not happen):

Illegal Case
GuC WOPCM Base & GuC WOPCM Size is not programmed (for copy to/from WOPCM) 0xC050 and 0xC340
DMA copy into GuC WOPCM that does not fit into the GuC WOPCM
DMA copy into SRAM that falls off the SRAM edge (except for uKernel copy)
DMA size is set to 0

GuC Interrupt (GUCINT) Register Functions

This section discusses the register functions for GuC Interrupt. Registers in this section are:

Functionality
Interrupt Group Registers
Doorbell Group Registers
Engine Interrupt Regiters
GuC Timer Registers
GuC DMA Interrupt Registers
GuC Host Registers

Interrupt Group Registers

GUCINT uses two registers to map all incoming interrupts to the 256-bit interrupt vector sent to the LAPIC. Internal to the LAPIC, the 256-bit interrupt vector is organized as 16 groups of 16 vectors. GUCINT maps each group of interrupts to a single group in the vector sent to LAPIC. Note that the higher the group number, the higher the priority of the group of interrupts to which it is assigned.

Interrupt Group Registers
INTR_GROUP_1 - Interrupt Group 1
INTR_GROUP_0 - Interrupt Group 0

The following interrupt groups are supported:

Interrupt Group
Doorbells (counts as 8 groups)
Semaphores
Engines
IOMMU
DMA/TIMER/FLR
HOST

Each group of interrupts needs 4 bits to map to the correct group in the 256-bit vector.

Interrupt Group 0 Register maps the 8 groups of Doorbells. **Interrupt Group 1 Register** maps the remaining 5 groups listed above.

Programming Note	
Context:	Interrupt Group Registers
• All groups must be unique. Only Doorbell groups may share a value with another doorbell group. • The group value cannot be 4'h1. That is illegal. This restriction applies to both GROUP registers. • Group values cannot dynamically change from one nonzero value to a different nonzero value.	

Doorbell Group Registers

There is a Doorbell Control Register in GUCint, which has a single doorbell_rung bit for each one of the eight Doorbell Registers located in GTI (1900 - 191C). GTI sets this GuC Register bit when the corresponding Doorbell register GTI houses, has that GTI register value going from all 0s to having any one bit set (any one of the 32 doorbells in that doorbell group gets rung).

GTI could set multiple first_doorbell_rung bits in a single message to the GuC based Doorbell Control Register (corresponding to several doorbells rung in different doorbell group registers in GTI). Once a doorbell_rung bit is set for a group in the Doorbell Control Register, it is not updated until GUCINT reads the corresponding GTI doorbell register, at which time the corresponding rung_bit is reset.

The doorbell control register also holds 1 bit (send to Mini-Core) that routes interrupts to host or Mini-Core. By default, interrupts are sent to host. This bit must be set by software (running on Mini-Core or host) to route interrupts to Mini-Core.

GUC_DB_ISR_7 - GuC Doorbell Group 7 Interrupt Status

GUC_DB_ISR_6 - GuC Doorbell Group 6 Interrupt Status

GUC_DB_ISR_5 - GuC Doorbell Group 5 Interrupt Status

GUC_DB_ISR_4 - GuC Doorbell Group 4 Interrupt Status

GUC_DB_ISR_3 - GuC Doorbell Group 3 Interrupt Status

GUC_DB_ISR_2 - GuC Doorbell Group 2 Interrupt Status

GUC_DB_ISR_1 - GuC Doorbell Group 1 Interrupt Status

GUC_DB_ISR_0 - GuC Doorbell Group 0 Interrupt Status

DOORBELL_CTRL - Doorbell Control

Engine Interrupt Registers

GUC gets Engine Event interrupts from various engines (Render, Copy, Compute, Video Decode, Video Enhancment ..).

GUCINT also gets Engine Event interrupts from OA.

The engines support a variety of interrupts that may not be interesting to GuC from a scheduling point of view. GUCINT provides an infrastructure to redirect engine interrupts to the host driver without invoking

the Mini-Core firmware. This infrastructure allows software to specify on a per engine and per interrupt granularity the interrupts that must be delivered to Mini-Core or simply forwarded to the host (bypassing the MiniCore).

Command Streamer Status Information

During execution, the Command Streamer Status is sent to the GuC.

Programming Note	
Context:	Context Status Buffer Initialization
GuC CSB FIFO's are implemented on device reset domain, its possible following GFX Reset (All engines and GuC are reset) there are unprocessed entries present in the engine CSB FIFO's. GuC FW as part of the GuC initialization flow must ensure the engine CSB FIFO's are drained and empty before scheduling contexts to the engines.	

CSB Read Port

The following RO registers are for use by GuC FW or host. SW must read twice to obtain a single CSB entry: the first read returns bits[31:0]; the second read returns [63:32].

CS CSB

BCS CSB

VCS CSB

VECS CSB

CSB FIFO Status Registers

The following RO registers hold the status of each Command Streamer's CSB FIFO:

CS CSB Fifo Status Register

BCS CSB Fifo Status Register

VCS CSB Fifo Status Register

VECS CSB Fifo Status Register

Guc DMA Interrupt Registers

GUC_DMA_IIR - GuC DMA Interrupt Input

The DMA generates this message interrupt at the completion of a programmed DMA transfer.

Guc Host Registers

GuC and Host(IA) communicate with each other through interrupts.

- A Host-to-GUC interrupt is generated by Host SW writing to 0xC4C8. The written data will get stored in 0xC590 and an interrupt will be generated to GuC.

- A GUC-to-Host interrupt is generated by GuC FW writing to 0xC4B8 - this generates a 16bit vector to the host (this 16b vector is shared by GuC HW and GuC FW. FW write can only set FW owned bits)

GUC_HOST_INTR_IIR - GuC Host Interrupt Interrupt Input

Observability

Observability Overview

As GFX-enabled systems and usage models have grown in complexity over time, a number of hardware features have been added to provide more insight into hardware behavior while running a commercially available operating system. This chapter documents these features with pointers to relevant sections in other chapters. Supported observability features include:

Feature
Performance counters
Internal node tracing

Note: This chapter describes the registers and instructions used to monitor GPU performance. Please review other volumes in this specification to understand the terms, functionality and details for specific Intel graphics devices.

DFD Configuration Restore

Since DFD logic does not usually add value to end user usage models and its configuration space is large (which would add latency to power management restore flows), it is typically not enabled during normal operation for optimal power & performance. Hence, additional steps are required when DFD functionality is needed in combination with system configurations where GT logic loses power/is reset. The basic strategy per scenario is detailed below.

GT Power-up/RC6 Exit

Strategy
Replicate failure without power management
Configure the DFD restore feature

Render Engine Power-up

Configure the RCS RC6 W/A batch buffer to restore render engine DFD configuration ONLY.

Media Engine Power-up

Configure the applicable media command stream W/A batch buffer to restore media engine DFD configuration ONLY.

Resume From Partial GT Power Down

For cases where SW is aware of power well state, re-apply DFD configuration.

For cases where SW is not aware of power well state, configure the per-context W/A batch buffer to apply the DFD configuration on every context load.

Trace

Feature
• Performance Visibility

Performance Visibility

Motivation For Hardware-Assisted Performance Visibility

As the focus on GFX performance and programmability has increased over time, the need for hardware (HW) support to rapidly identify bottlenecks in HW and efficiently tune the work sent to same has become correspondingly important. This part of the BSpec describes the HW support for Performance Visibility.

Performance Event Counting

An earlier generation introduced dedicated GFX performance counters to address key issues associated with existing chipset CHAPs counters (lack of synchronization with GFX rendering work and low sampling frequency achievable when sampling via CPU MMIO read). Furthermore, reliance on SoC assets created a cross-IP dependency that was difficult to manage well. Hence, the approach since that earlier generation has been to use dedicated counters managed by the graphics device driver for graphics performance measurement. The dedicated counter values are written to memory whenever an MI_REPORT_PERF_COUNT command is placed in the ring buffer.

While this approach eliminated much of the error associated with the previous approaches, it is still limited to sampling the counters only at the boundaries between ring commands. This inherently limited the ability of performance analysis tools to drill down into a primitive, which can contain thousands of triangles and require several hundreds of milliseconds to render. It is further worth noting that precise sampling via MI_REPORT_PERF command requires flushing the GFX pipeline before and after the work of interest. The overhead of flushing the GFX pipeline can become large if the work of interest is small, hence reducing the accuracy of the performance counter measurement. In such situations, the flush can be removed or internally triggered reporting can be used with some resulting loss of precision in which draws/dispatches are being profiled.

Additionally, Intel design and architecture teams found that the existing silicon-based performance analysis tools provided only a general idea of where a problem may exist but were not able to pin point a problem. This was generally because the counter values are integrated across a very large time period, washing out the dynamic behavior of the workload.

All OA config registers are tied to GT global reset and hence are not affected by per-engine resets (e.g. render only reset).

OA Programming Guidelines

SW utilizing OA HW is expected to monitor the overflow/lost report status for the OABUFFER and respond as appropriate for the active usage model.

In order for OA counters to increment the 'Counter Stop-Resume Mechanism' bit of the OACTXCONTROL register must be set. This requires a RCS context with this bit set be loaded, and either RCS force wake be enabled or the RCS context be left active for the duration of the window this counter is needed for.

In general, OA is effectively unable to count between the power context save that happens prior to GFX entering RC6 and the power context restore that occurs on the next RC6 exit. This limitation results from the fact that the counters themselves are power context save/restored and hence the counts that (may) have accumulated in this time window are overwritten by the saved values that are read back from the power context save area. An example of the kind of information that can be missed is the GTI traffic resulting from the power context save of OA itself. The size of this performance counting blind spot is microarchitecturally minimized as much as reasonably possible but still varies from device to device.

Legacy OACS functionality is now logically split into two functions called OAG (OA Global) and OAR (OA Render). Summary of the blocks is as follows:

OAG:

- Handles OA buffer and timer/internally-triggered sampling.
- Is unaffected by engine reset / power well status.
- Is inaccessible by non-privileged batch buffers but accessible by all command streamers / GuC / CPU.
- Implements free-running utilization counters.
- Is GT power context save/restored.
- Is only allowed to access global GTT memory.

OAR:

- Is expected to behave as a part of the render engine from a clocking/power well/reset perspective.
- Implements MI_REPORT_PERF command.
- Is render context save/restored, making all values reported by MI_REPORT_PERF per-context.
- Must be initialized to power-on default values as part of RCS golden context creation (please refer to RCS section describing golden context creation for full details) or implementation-specific undesirable behavior may occur.
- Doesn't support timer/internally-triggered sampling.
- Can be enabled/disabled independent from OAG.

Is only intended to be accessed by RCS, access from other command streamers / CPU may have implementation-specific negative side-effects.

HW Support

This section contains various reporting counters and registers for hardware support for Performance Visibility.

Performance Counter Report Formats

Counters layout for various values of select from the register:

Description of RPT_ID and other important fields of the layout:

Field	Description
GPU TICKS[31:0]	GPU_TICKS is simply a free-running count of render clocks elapsed used for normalizing other counters (e.g. EU active time), it is expected that the rate that this value advances will vary with frequency and freeze (but not lose its value) when all GT clocks are gated, GT is in RC6, and so on.
Context ID[31:0]	This field carries the Context ID of the active context in render engine. [31:0]: Context ID in Execlist mode of scheduling.
TIME_STAMP[31:0]	This field provides an elapsed real-time value that can be used as a timestamp for GPU events over short periods of time. This field has the same format at TIMESTAMP register defined in Vol1C.4 Render Command Streamer BSpec.
RPT_ID[46:38]	Reserved (for future use)
RPT_ID[35:34]	Reserved (for future Tile IDs)
RPT_ID[31:0]	This field has several sub fields as defined below: 31:26 **SourceID[5:0]**

Field	Description	
		Encoded value to identify various sources like any CS or Shader unit from which the Report was requested. **Programming note:**
	25:19	**Report Reason[6:0]** Report_reason[0]: When set indicates current report is due to "Timer Triggered". Report_reason[1]: When set indicates current report is due to "Internal report trigger 1". Report_reason[2]: When set indicates current report is due to "Internal report trigger 2". Report_reason[3]: When set indicates current report is due to "Context switch". Report_reason[4]: When set indicates current report is due to "GO transition from '1' to '0' ". Report_reason[5]: When set indicates current report is due to a change in unslice/slice ratio Report_reason[6]: When set indicates current report is due to a MMIO Trigger **Programming note:**
	18	**Start Trigger Event:**This bit is multiplexed from "Start Trigger Event-1" or "Start Trigger Event-2" based on the "Internal Report Trigger-1" or "Internal Report Trigger-2" asserted in the Report Reason respectively. "Internal Report Trigger-1" is given priority over "Internal Report Trigger-2". By default Start Trigger Event-1 is outputted.
	17	**Threshold Enable:** This bit is multiplexed from "Report Trigger Threshold Enable-1" or "Report Trigger Threshold Enable-2" based on the "Internal Report Trigger-1" or "Internal Report Trigger-2" asserted in the Report Reason respectively. "Internal Report Trigger-1" is given priority over "Internal Report Trigger-2". By default "Report Trigger Threshold Enable-1" is outputted.
	16	**Timer Enabled**
	15:0	Reserved

OA Interrupt Control Registers

The Interrupt Control Registers listed below all share the same bit definition. The bit definition is as follows:

Bit	Description
31:29	**Reserved. MBZ:** These bits may be assigned to interrupts on future products/steppings.
28	**Performance Monitoring Buffer Half-Full Interrupt:** For internal trigger (timer based) reporting, if the report buffer crosses the half full limit, this interrupt is generated.
27:0	**Reserved: MBZ (These bits must be never set by OA, these bit could be allocated to some other unit)**

- **WDBoxOAInterrupt Vector**
- IMR
- Bit Definition for Interrupt Control Registers

Performance Counter Reporting

When either the MI_REPORT_PERF_COUNT command is received or the internal report trigger logic fires, a snapshot of the performance counter values is written to memory. The format used by HW for such reports is selected using the Counter Select field within the register. The organization and number of report formats vary per project and are detailed in Here.

Details of Start Trigger Behavior

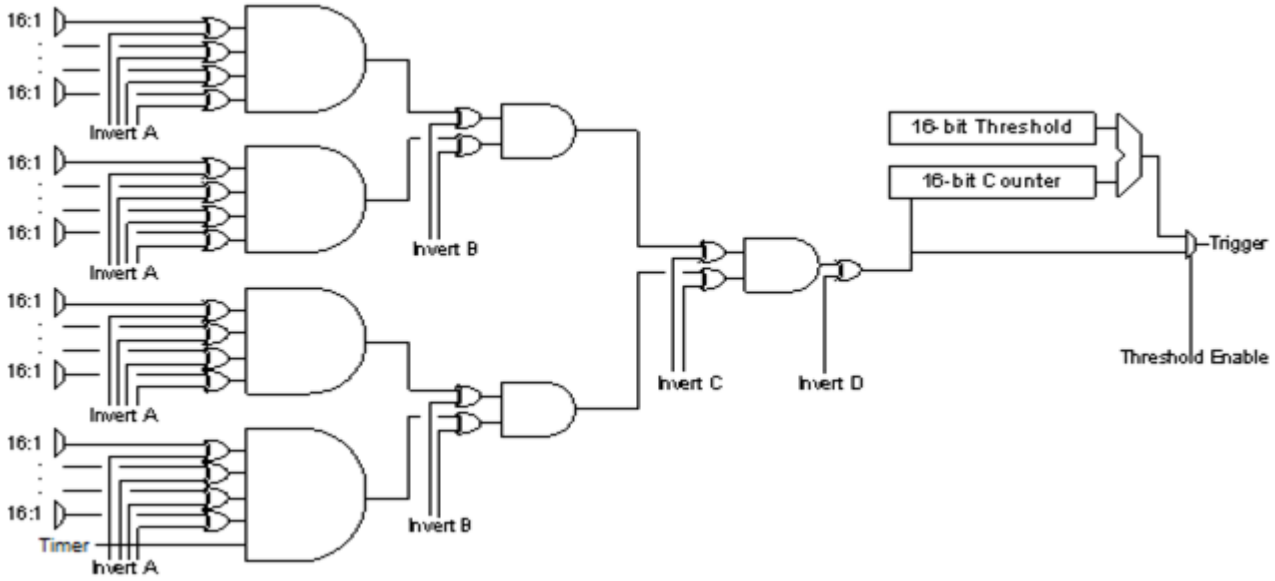
- All counters not explicitly defined as free-running will advance after the start trigger conditions are met.
- Counting will continue after the start trigger has fired until OA is disabled or device is reset.
- Multiple start triggering blocks (where implemented) are OR'd together in order to allow specification of multiple trigger conditions.
- Bit 18 in the report format reflects whether the start trigger has fired or not.

While architectural intent was that Start Trigger logic would control all qualified counter types (A/B/C), there is a long-standing implementation bug whereby start trigger logic only affects B/C counters.

Configuration of Trigger Logic

OA contains logic to control when performance counter values are reported to memory. This functionality is controlled using the OA report trigger and OA start trigger registers. More detailed

register descriptions are included in the Hardware Programming interface. The block diagram below illustrates the logic these registers control.



Note that counters which are 40 bits wide are split in the report format into low DWORD and high byte chunks for simplicity of HW implementation as well as SW-friendly alignment of report data. The performance counter read logically done before writing out report data for these 40-bit counters is guaranteed to be an atomic operation, the counter data is simply swizzled as it is being packed into the report.

Context Switch Triggered Reports

A context load/switch on RCS will cause a performance counter snapshot to be written to memory at the next location in the OA circular report buffer using the perf counter format selected in OACONTROL (). This functionality can be leveraged when preemption is enabled to re-construct the contribution of a specific context to a performance counter delta, requires SW to consider both the delta reported by MI_REPORT_PERF and the reports that may have been issued to OABUFFER by intervening contexts.

A context load/switch on RCS will cause a performance counter snapshot to be written to memory at the next location in the OA circular report buffer using the perf counter format selected in **OARCONTROL**. This functionality can be leveraged when preemption is enabled to re-construct the contribution of a specific context to a performance counter delta, requires SW to consider both the delta reported by MI_REPORT_PERF and the reports that may have been issued to OABUFFER by intervening contexts.

Frequency Change Triggered Reports

A GFX frequency change will cause a performance counter snapshot to be written to memory at the next location in the OA circular report buffer using the perf counter format selected in OACONTROL (). Please note that a change back to the same frequency can occur and that such changes will still cause a performance counter report to occur.

A GFX frequency change will cause a performance counter snapshot to be written to memory at the next location in the OA circular report buffer using the perf counter format selected in **OARCONTROL**. Please

note that a change back to the same frequency can occur and that such changes will still cause a performance counter report to occur.

Aggregating Counters

The table below described the desired high-level functionality from each of the aggregating counters.

Note that there is no counter of 2x2s sent to pixel shader, this is based on the assumption that the pixel shader invocation pipeline statistics counter increments for partially lit 2x2s as well and hence does not require a duplicate performance counter.

Please also note that some of the information provided by A-counters is useful for GFX/system load-balancing and is hence made available via free-running counters which do not require initial setup and count irrespective of OA enable/disable or freeze.

Counter #	Event	Description
A0	GPU Busy	GPU is not idle (includes all GPU engines).
A1	# of Vertex Shader Threads Dispatched	Count of VS fused threads dispatched to EUs
A2	# of Hull Shader Threads Dispatched	Count of HS fused threads dispatched to EUs
A3	# of Domain Shader Threads Dispatched	Count of DS fused threads dispatched to EUs
A4	# of GPGPU Threads Dispatched	Count of GPGPU fused threads dispatched to EUs. Available on both qualified and free-running counters.
A5	# of Geometry Shader Threads Dispatched	Count of GS fused threads dispatched to EUs
A6	# of Pixel Shader Threads Dispatched	Count of PS fused threads dispatched to EUs. Available on both qualified and free-running counters.
A7	Aggregating EU counter 0	User-defined (details in Flexible EU Event Counters section)
A8	Aggregating EU counter 1	User-defined (details in Flexible EU Event Counters section)
A9	Aggregating EU counter 2	User-defined (details in Flexible EU Event Counters section)
A10	Aggregating EU counter 3	User-defined (details in Flexible EU Event Counters section)
A11	Aggregating EU counter 4	User-defined (details in Flexible EU Event Counters section)
A12	Aggregating EU counter 5	User-defined (details in Flexible EU Event Counters section)
A13	Aggregating EU counter 6	User-defined (details in Flexible EU Event Counters section)
A14	Aggregating EU counter 7	User-defined (details in Flexible EU Event Counters section)
A15	Aggregating EU counter 8	User-defined (details in Flexible EU Event Counters section
A16	Aggregating EU counter 9	User-defined (details in Flexible EU Event Counters section)
A17	Aggregating EU counter 10	User-defined (details in Flexible EU Event Counters section)
A18	Aggregating EU counter 11	User-defined (details in Flexible EU Event Counters section)
A19	Aggregating EU counter 12	Available on both qualified and free-running counters

Counter #	Event	Description
		User-defined (details in Flexible EU Event Counters section)
A20	Aggregating EU counter 13	Available on both qualified and free-running counters User-defined (details in Flexible EU Event Counters section)
A21	2x2s Rasterized	Count of the number of samples of 2x2 pixel blocks generated from the input geometry before any pixel-level tests have been applied. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.)
A22	2x2s Failing Fast pre-PS Tests	Count of the number of samples failing fast "early" (i.e. before pixel shader execution) tests (counted at 2x2 granularity). (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.)
A23	2x2s Failing Slow pre-PS Tests	Count of the number of samples of failing slow "early" (i.e. before pixel shader execution) tests (counted at 2x2 granularity). (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.)
A24	2x2s Killed in PS	Number of samples entirely killed in the pixel shader as a result of explicit instructions in the kernel (counted in 2x2 granularity). (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.)
A25	2x2s Failing post-PS Tests "POSTPS_DEPTH_STENCIL_ALPHA_FAIL"	Number of samples that entirely fail "late" tests (i.e. tests that can only be performed after pixel shader execution). Counted at 2x2 granularity. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.)
A26	2x2s Written To Render Target	Number of samples that are written to render target.(counted at 2x2 granularity). MRT case will report multiple writes per 2x2 processed by the pixel shader. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) Please note that this counter will not advance if a render target update does not occur and that pixel masking operations performed by the fixed function HW or shader may not be reflected in counters A22-A25 which only track their specific defined operations. This can lead to an apparent discrepancy between A21 vs. A22-A25 vs. A26/A27.
A27	Blended 2x2s Written to Render Target	Number of samples of blendable that are written to render target.(counted at 2x2 granularity). MRT case will report multiple writes per 2x2 processed by the pixel shader. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) Please note that this counter will not advance if a render target update does not occur and that pixel masking operations performed by the fixed function HW or shader may not be reflected in counters A22-A25 which only track their specific defined operations. This can lead to an apparent discrepancy between A21 vs. A22-A25 vs. A26/A27.

Counter #	Event	Description
A28	2x2s Requested from Sampler	Aggregated total 2x2 texel blocks requested from all EUs to all instances of sampler logic.
A29	Sampler L1 Misses	Aggregated misses from all sampler L1 caches. Please note that the number of L1 accesses varies with requested filtering mode and in other implementation specific ways. Hence it is not possible in general to draw a direct relationship between A28 and A29. However, a high number of sampler L1 misses relative to texel 2x2s requested frequently degrades sampler performance.
A30	SLM Reads	Total read requests from an EU to SLM (including reads generated by atomic operations).
A31	SLM Writes	Total write requests from an EU to SLM (including writes generated by atomic operations).
A34	Atomic Accesses	Aggregated total atomic accesses from all EUs. This counter increments on atomic accesses to both SLM and URB. **Workaround** SLM atomics are not included in prior releases by this OA event (only global memory atomics are counted), a workaround using B/C counters is possible.
A35	Barrier Messages	Aggregated total kernel barrier messages from all Eus (one per thread in barrier).

SPM Counters

Counter #	Event	Description
SPM0	EU Stall	Event reflects the condition where an EU is not idle but also not processing an ISA instruction. Each increment of the event reflects 4 clocks where a single EU met this condition.
SPM1	EU IPC	Event counts the number of ISA FPU/EM instructions that GT processes. It comprehends cases where multiple instructions are processed in a single clock. Each increment of this event reflects 8 instructions processed.
SPM2	Threads loaded	Event counts the total number of threads that have been fully loaded onto an EU in a given clock. This event DOES NOT include the time where the thread header is being sent to the EU. The per-clock increment is added to an accumulator each clock, a single increment of this event reflects that the accumulator has reached 8.
SPM3	EU Not Idle	Event reflects the condition where an EU is not idle. Each increment of the event reflects 8 clocks where a single EU met this condition.

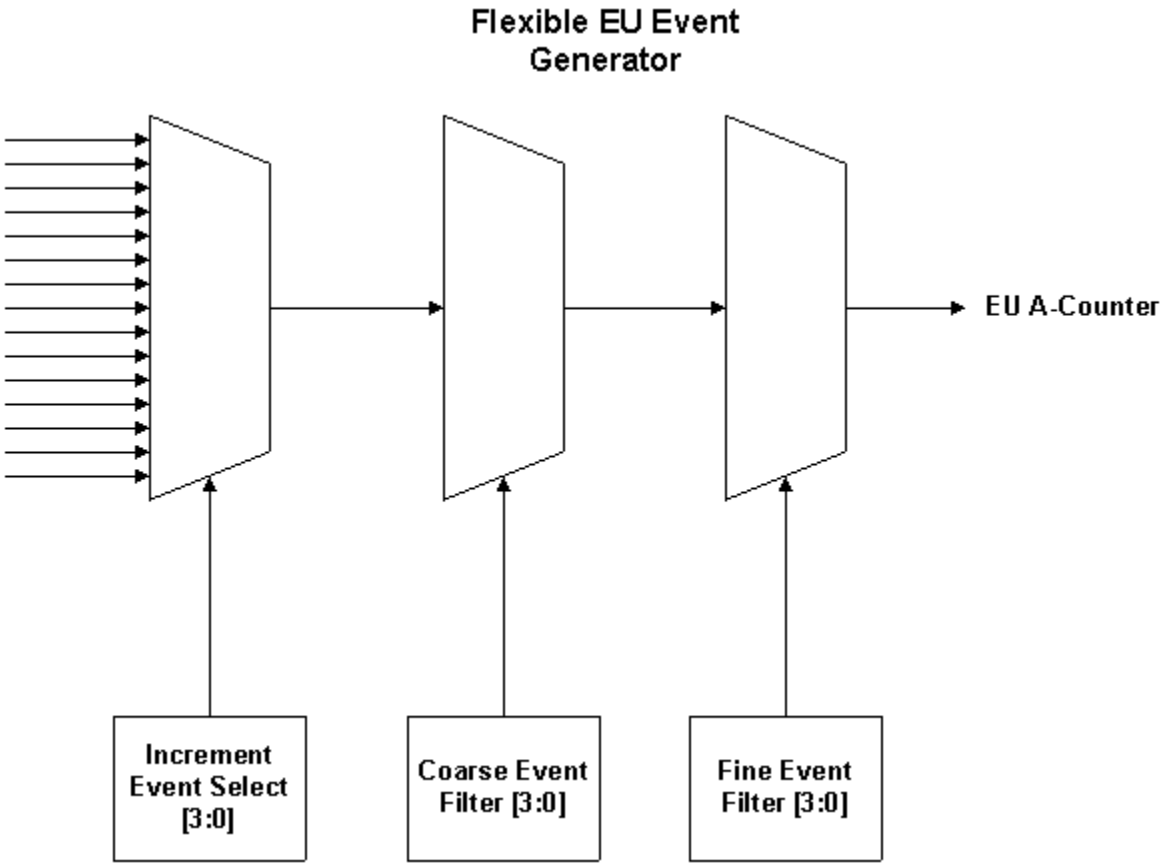
Counter #	Event	Description
SPM4	Sampler Not Idle	Event counts sampler activity.
SPM5	EU Stalled & Sampler Not Idle	Event reflects the condition where the EU has sent a request(s) to sampler and all threads on the EU are stalled. Please note that the EU could be stalled for reasons other than sampler as well. Each increment of the event reflects 8 clocks where a single EU met this condition.

Flexible EU Event Counters

Since EU performance events are most interesting in many cases when aggregated across all EUs and many interesting EU performance events are limited to certain APIs (e.g. hull shader kernel stats only applicable when running a DX11+ workload).

The following block diagram shows the high-level flow that generates each flexible EU event.

Note that no support is provided for differences between flexible EU event programming between EUs because the resulting output from each EU is eventually merged into a single OA counter anyway.



Supported Increment Events

Increment Event	Encoding	Notes
EU_INST_EXECUTED_ALU0_ALL	0b00000	Signal that is high on every EU clock where the EU FPU pipeline is actively executing an ISA instruction.
EU_INST_EXECUTED_ALU1_ALL	0b00001	Signal that is high on every EU clock where the EU EM pipeline is actively executing an ISA instruction.
		Only fine event filters 0b0000, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
EU_INST_EXECUTED_SEND_ALL	0b00010	Number of instructions executed on SEND Pipe. Only fine event filters 0b0000,0b0101, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
EU_PIPE_ALU0_AND_ALU1_ACTIVE_CYCLES	0b00011	Signal that is high on every EU clock where the EU FPU and EM pipelines are both actively executing an ISA instruction. Only coarse event filters 0b0000, 0b0111, and 0b1000 are supported with this increment event. Only fine event filters 0b0000, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
EU_ACTIVE_CYCLES	0b00100	Number of occurrences of signal that is high on every EU clock where at least one EU pipeline is actively executing an ISA instruction. All coarse event filters are supported. Only fine event filters 0b0000,0b0101, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
EU_STALL_CYCLES	0b00101	Number of occurrences of signal that is high on every EU clock where at least one thread is loaded but no EU pipeline is actively executing an ISA instruction. All coarse event filters are supported. Only fine event filters 0b0000, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
EU_THREADS_OCCUPANCY_ALL	0b01000	Number of Thread slots occupied. Accumulated every clock. Implies an accumulator which increases every EU clock by the number of loaded threads, signal pulses high for one clock when the accumulator exceeds a multiple of the number of thread slots (e.g. for a 8-thread EU, signal pulses high every clock where the increment causes a 3-bit accumulator to overflow). Only coarse event filters 0b0000, 0b0111, and 0b1000 are supported with this increment event. Only fine event filters 0b0000, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
	0b01111	Expected HW default, allows logic to be power-optimized.

Supported Coarse Event Filters

Coarse Event Filter	Encoding	Notes
No mask	0b0000	Never masks increment event.
VS Thread Filter	0b0001	For increment events 0b00000/0b00001/0b00010, masks increment events unless the FFID which dispatched the currently executing thread equals FFID of VS.
		For increment events 0b00100/0b00101, masks increment event unless at least one of the loaded threads was dispatched by VS.
HS Thread Filter	0b0010	For increment events 0b00000/0b00001/0b00010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of HS.
		For increment events 0b00100/0b00101, masks increment event unless at least one of the loaded threads was dispatched by HS
DS Thread Filter	0b0011	For increment events 0b00000/0b00001/0b00010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of DS.
		For increment events 0b00100/0b00101, masks increment event unless at least one of the loaded threads was dispatched by DS.
GS Thread Filter	0b0100	For increment events 0b00000/0b00001/0b00010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of GS.
		For increment events 0b00100/0b00101, masks increment event unless at least one of the loaded threads was dispatched by GS.
PS Thread Filter	0b0101	For increment events 0b00000/0b00001/0b00010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of PS.
		For increment events 0b00100/0b00101, masks increment event unless at least one of the loaded threads was dispatched by PS.
TS Thread Filter	0b0110	For increment events 0b00000/0b00001/0b00010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of TS.
		For increment events 0b00100/0b00101, masks increment event unless at least one of the loaded threads was dispatched by TS.
Row = 0	0b0111	Masks increment event unless the row ID for this EU is 0 (control register is in TDL so only have to check within quarter-slice).

Fine Event Filters

Fine Event Filter	Encoding	Notes
None	0b0000	Never mask increment event.
Cycles where hybrid instructions are being executed	0b0001	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are hybrid instructions.
Cycles where ternary instructions are being executed	0b0010	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are ternary instructions.
Cycles where binary instructions are being executed	0b0011	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are binary instructions.
Cycles where mov instructions are being executed	0b0100	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are mov instructions.
Cycles where sends start being executed	0b0101	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are send start of dispatch. Note that if this fine event filter is used in combination with increment events not related to the EU send pipeline (e.g. FPU0 active), the associated flexible event counter will increment in an implementation-specific manner.
EU# = 0b00	0b0111	Masks increment event unless the EU number for this EU is 0b00.
EU# = 0b01	0b1000	Masks increment event unless the EU number for this EU is 0b01.
EU# = 0b10	0b1001	Masks increment event unless the EU number for this EU is 0b10.
EU# = 0b11	0b1010	Masks increment event unless the EU number for this EU is 0b11.

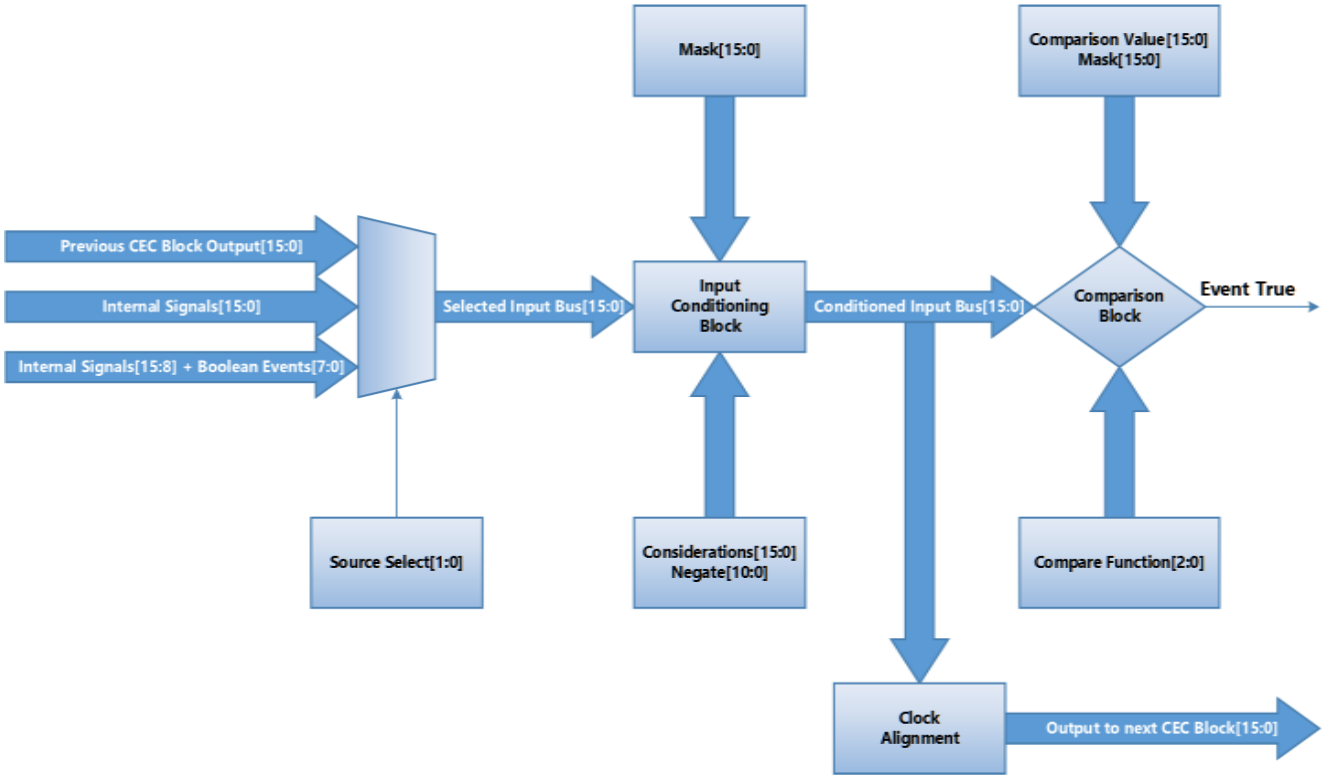
Custom Event Counters

Also known as B-counters, the events counted in these counters are defined from Boolean combinations of input signals using the custom event creation logic built into OA.

The following diagram(s) illustrate(s) the structure used to create a custom event. Every B-counter has such a block.



MI_REPORT_PERF_COUNT

MI_REPORT_PERF_COUNT

GPU Doorbells

On current platforms, graphics workload is submitted to the graphics hardware through multiple SW layers: Application, user mode driver (UMD), Graphics Runtime, kernel mode driver (KMD) and then finally down to hardware. This submission path incurs the penalty of traversing the various SW layers and then a ring3-to-ring0 switch when the kernel mode driver finally submits the workload by writing to some graphics register. With the advent of the GPGPU computing, applications like to use the parallelism provided by the graphics hardware for graphics and non-graphics workloads. However, due to the large latency introduced by the legacy submission mechanism, an App has to determine if the computation cycles required for a workload exceeds a threshold to justify incurring the latency that will be incurred to get this workload running on the graphics hardware.

The proposed GFX doorbell solution provides a mechanism for submission of workload to the graphics hardware by a ring3 application - without the penalty of ring transition for each workload submission. The structure has the following components:

- Assignment of a work queue page by Kernel Mode driver into an Apps address space
- Infrastructure in GTI/BGF to detect submission of work into a N work queue pages; GTI detects a write to a specific cacheline in the doorbell page.

- Message from GTI/BGF to a micro-controller in the graphics engine indicating new work has arrived in a queue.
- Microcontroller inspects queue and determines the specific graphics engine to submit the workload to (render engine,...).

Essentially, the hardware will support monitoring of 256 cache-line addresses that are on separate 4KB pages. Each GPGPU App/thread negotiates with KMD on the address of this 4KB page (in app's space) as a "doorbell" page. This negotiation happens during the app's call to the driver (KMD) for open GPGPU. The page is assigned for doorbell operation which is basically a way to MONITOR accesses to the specified cacheline within the doorbell page.

This portion of the document details the interactions needed in GT BGF Doorbell Block as well as the HW pieces.

The Concept and Usage Flow

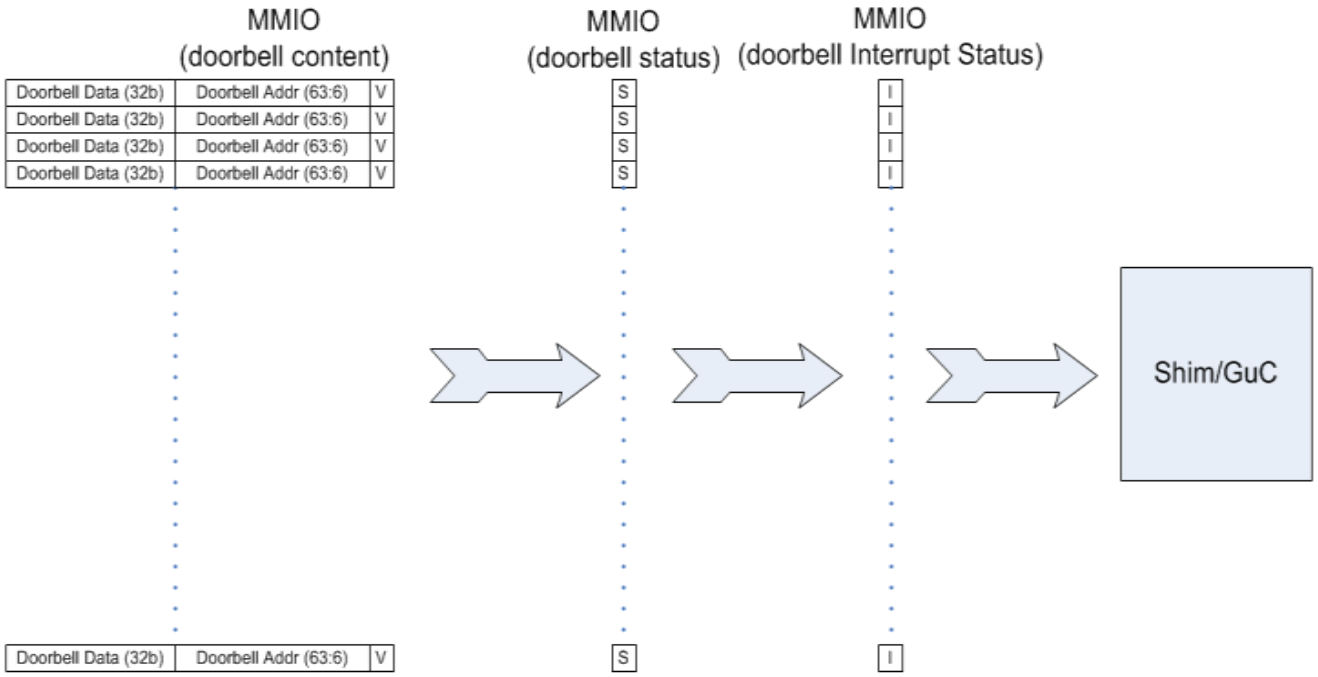
The interactions between the doorbell hardware and software flows described as viewed from the doorbell controller:

Doorbell Structures

Doorbell structures for reporting have been separated into three logical blocks in the hardware. First stage is where doorbell address is stored along with Valid bit. Once Valid is set (written by KMD/GuC), doorbell block will start monitoring and store the cookie value (DW[0] of the doorbell line).

Once a doorbell is triggered corresponding Status bit is set. Eventually status is propagated to interrupt status bit, meanwhile multiple triggers on doorbell will be collapsed within the status bits.

A read from interrupt status stage to doorbell status stage moves the bits to interrupt status register and clears the doorbell status register.



All stages are exposed via MMIO:

Doorbell Address. Read/Write support for the driver, but thru GuC/Shim (no direct updates).

Valid. Read/Write support however there are restrictions which hardware needs to ensure:

- 0=>1 transition only from GuC via message channel (not allowed for any other message channel client and memory reads of related doorbell does not change the doorbell value from 0=>1.
- 1=>0 transition is only from memory read that doorbell block does when it needs to acquire the doorbell cookie.

Hardware has to guarantee proper clients make the transitions.

Doorbell Status. Read Only (updates are HW managed).

Doorbell Interrupt Status. Read/Write - it is set by hardware and cleared by driver/GuC.

Doorbell Page and Cacheline

As part of the "*openGPGPU*" call between the App and GFX driver a doorbell page is assigned. The page is allocated within the WB space (requirement) and pinned to prevent any faulting while exchanging semaphores (requirement). The doorbell monitoring hardware operates on each doorbell at a 64B granularity.

App and KMD negotiates which cacheline (64Byte) entity within the doorbell page should be picked as doorbell line. Even though this could be simply the first 64B of the page, it is highly recommended to pick a rotating 64B entity to maximize the hardware performance. The suggested algorithm should be:

Doorbell CL# = Bell# mod 64

This simply means Bell0,64,128,192 goes to CL0 of the page, Bell1,65,129,193 goes to CL1 of the page, Bell2,66,130,194 goes to CL2 of the page, and so on.

Only the first 2 DWords of the Doorbell CL is relevant, the rest is not used by the doorbell hardware. Same is also applicable for the rest of page which could be utilized for some other means.

1st DWord (4 bytes) contains 1-bit for doorbell status: Active vs. Inactive:

- Active - Bit0=1: Doorbell is Active for Application.
- Inactive - Bit0=0: Doorbell is suspended for the Application, hence Application should re-negotiate the doorbell.

Note that as part of the negotiation a different cacheline can be picked within the doorbell page, different than what was originally agreed between GFX Driver and Application.

GFX driver control the initial setting of bit[0] of DW[0] to enable and disable doorbell for a given application. However HW setup of doorbell can be done only via GuC and disabling in HW is self-detected via snooping driver's clearing of DW0[0].

2nd DWord (4 bytes) carries a cookie value. It is reset to "0h" by the GFX driver prior to being assigned and acquired and incremented by the App. Note that value "0h" is a reserved value for cookie which App should never write. A roll-over increment should go from "FFFF_FFFFh" to "0000_0001h". Details on how cookie and flag value should be processed by application and hardware are given in later sections.

Work Queue and DoorBell Creation

App calls the driver for "OpenGPU()API", UMD calls the KMD and KMD sets up the queues. KMD maps the queue addresses to application space. KMD assigns a doorbell if one available:

- **If available:** Doorbell page gets allocated and assigned to Applications space. Doorbell cacheline is decided and QW0 is initialized as:
  - DW0 = "0000_0001h"
  - DW1 = "0000_0000h"
- **If not-available:** Driver has to victimize doorbell from an existing application and wait for it to clear from HW before assigning to new application requesting one.

KMD assigns a unique ID (i.e. Context ID) which is a 32b value to define the context. KMD allocates HW context memory for "State" - up to 3MB.

Note that the SW flows here are a high level description; the actual flows may contain further steps and will be detailed in SAS.

KMD communicates the contextID as a handle to memory (work queue) to GuC. If there is a doorbell assignment, GuC also receives the doorbell number as well as the physical address of the cacheline decided.

GuC has to ensure there are no pending doorbell events before updating the doorbell register for use. To ensure this, GuC should read "doorbell status vector". If there are any pending events to the same doorbell that is about to be assigned, GuC expedites the service of the matching vector and waits for

status to clear. If status is cleared, GuC needs to check the "doorbell interrupt status" register in the GuC/Shim to ensure there are no pending interrupts. Once both stages are clear, GuC can proceed with re-assignment of the doorbell.

The doorbell address is GPA. Rest of the flow is between the GuC Shim/GAM and Doorbell control block:

- GuC the address (GPA) of the doorbell page/cacheline. Given the address is GPA, a 2nd level page table translation is required before the monitor address can be written to doorbell block.
- GuC sends the following message pair to GAM asking for a GPA to HPA translation.
- Doorbell Address programming has to be routed thru GuC/Shim - driver (KMD) is not allowed to update the doorbell addresses directly.

Doorbell Flows

Doorbell Controller has a single primary flow of acquiring the ownership of a doorbell cacheline and detecting and reporting doorbell rings. Besides the main flow, there is various side flows to handle power states.

There are two cases where the main (ownership) flow can be invoked:

1. VALID bit in one of the doorbell registers transitions from 0=>1 indicating a new assignment of doorbell. This is considered initial flow.
2. A snoop from LLC/Cbo removing the ownership of a doorbell cacheline that was already being monitored. This is considered subsequent flow.

Both flows are handled same, as they overlap whether this is the initial ownership flow or subsequent case.

Doorbell controller collects the results of the RFO where data gets processed:

- If DW0[0] - flag - is seen as "0", that means s/w already victimized the doorbell and in the process of re-assigning it. However it is possible that application had a chance to sneak in work at the very last opportunity. And the doorbell register is still valid.
- If DW0[0] - flag - is seen as "1", the doorbell is still active.

Both cases are handled similarly in the doorbell controller.

- The value of cookie is checked:
  - If cookie is "0000_0000h", this is the initialized value of the cookie by GFX driver. Application did not use the doorbell yet. Doorbell block initializes the cookie value stored in h/w and does not ring the bell.
  - If cookie is same as what was stored in the cookie register this means either we are still at the initialized value or the ownership was lost due to LLC victimization and there is no RING event.
  - If cookie value is different than the previous value and it is not all "0's", this is a VALID RING event.
- In case of a valid RING event,

    - Doorbell controller sets up the corresponding bit flag in the "Active Doorbell Status Vector".
    - If in RC6, generate a wake-event to GT-Shim pm block.
        - Doorbell Block has to be aware of the RC6 status and need to be able to communicate the wake up request to Shim-PM block.
        - The message to Shim has to be hold-off until we wake up GT.
    - If not in RC6 or woken up from RC6, generate a message to GuC unless the 32b group of active vector is non-Zero. Meaning there has been already a message to Guc and GuC did not have a chance to read the corresponding "Active Doorbell Vector" piece. The communication between the doorbell monitoring hardware and GuC is handled via internal messaging.
- Once a group's message is sent (via message channel) subsequent rings to the same group does not cause a message to GuC. The only time a message is sent if the previous value of the doorbell vector for the corresponding group was "0000_0000h".
- At some point, GuC will read the vector from the doorbell block to see which doorbells have rung. Same read event should clear the corresponding doorbell vector register allowing any subsequent rings to generate a new message back to GuC.

Assigning Doorbells

Doorbells assignments are straight forward - see doorbell creation section

In addition s/w shall not assign the same cacheline to more than one doorbell. Such assignments will create unexpected behavior when the doorbell is rung.

Removing Doorbells

Doorbells are floating hardware resources, and they can be temporarily attached to Apps. GFX Driver can remove an application's doorbell without the need to notify or negotiate with that App. The removal process described requires KMD to poll doorbell status locations in HW to ensure doorbell is freed before re-assigning. And re-assignment process is done making sure all previous interrupts from this doorbell are processed.

An application losing a doorbell simply needs to request one as it realizes that its doorbell is lost. This is considered as a doorbell virtualization process where GFX driver and GuC can move a limited number of doorbells between a practically unbounded (2^31) number of applications.

The removal processes for doorbells are managed by the driver (KMD). However, it is completely asynchronous to what applications are doing with the doorbells and where HW is in processing these doorbells. The following flow is used to de-activate a doorbell.

As part of the de-activation:

1. GFX driver decides which doorbell to victimize and clears the DW0[0] of the doorbell cacheline in WB space. This is an indication to the GPU doorbell controller that the corresponding doorbell is removed. The doorbell block in GPU will see the update from IA core as part of the snoop monitoring (see later sections on how application checks the flag via compare&exchange).

From this point on, Application will not be able to ring that doorbell, and it needs to request a new one once it realizes its doorbell is lost.

2. The GFX driver clearing DW0[0] of the doorbell is seen by the GFX doorbell hardware as de-activation. However, there is a possibility that the App had a chance to use it to increment the cookie just before doorbell got de-activated. The doorbell block compares the cookie value new vs old to make a decision to set the interrupt status bit or not.

   From this point on we know that the particular doorbell cannot be used and HW will not match incoming snoops even if there may be snoops to the line (Valid bit is managed by the HW when getting cleared).

3. After GFX driver clears the DW0[0] of the doorbell that is getting victimized, it polls the doorbell register VALID bit in HW which indicates when HW got to see the victimized doorbell and cleared the VALID bit state. This also ensures that all previous updates of the victim doorbell are now registered in the HW.
4. Once the GFX driver sees the VALID bit cleared in the doorbell register, it is free to re-allocate the same doorbell for another APP. Note that assignment of the doorbell requires GuC to clear all previous usages of the previous owner of that doorbell.

Now the doorbell is ready to be re-assigned to any application.

Application Flow

The application use of doorbell is described in this document for completeness and to give the design owners what to expect.

Application can start using the doorbell once agreed with the GFX driver, from this point the main part of the flow is to be able cache the value of the cookie (if initial assignment application knows cookie is "0" and next value is "1"). The flow relies on the fact that application simply increments the cookie by "1" to indicate a doorbell event. And application has the value of cookie and the next value that it wants to update to. To understand how the rest of the sequence works, one needs to understand the inner works of the LOCK_CMPXCHG8B.

1. Assumption thread knows the value of the cookie - if this is the first time using it, it knows KMD initialized to "0". Thread prepares ECX = 1
2. Thread does compare exchange 8B (LOCK_CMPXCHG8B)

a. Outcome#1: **Success** - thread gets "ZF == 1", rings the doorbell successfully and resumes execution

b. Outcome#2: **Fail:** Bell is present (EAX =1) but EDX is not the expected value - *means some other thread is sharing the same bell.*

   i. Load ECX with EDX, and INC ECX - *prepare the next value for destination*

   ii. And loop to compare exchange (step#2) - *at this point this is a RACE to the bell between multiple threads. The thread that succeeds updates the bell*

c. Outcome#3: **Fail** : Bell is not there (EAX = 0) - ask for a bell and loop to step#1

In both cases algorithm is self correcting. For the case of one doorbell to one application thread, Outcome#2 is never possible given the application thread exactly knows what the value of the cookie is (it is the only thread writing to it). Outcome#3 is possible if GFX driver decides to remove the doorbell.

For the case of one doorbell to many application threads, each application thread has an idea of what the value of the cookie could be. If this is the first time the thread is writing the cookie value, it assumes "0"; if not the first time, it assumes whatever the value it wrote last time. In this case Outcome#2 becomes possible given that other threads are doing LOCK_CMPXCHG8B on the same data structure as well. However the good part of the LOCK_CMPXCHG8B is that, operation is atomic and a fail case (i.e. mismatch of the compare) returns the most up to date value from memory and does not change the contents of the memory. For multiple application-thread case, all threads are going to be racing to the flag while making successful updates and any doorbell ring is going to get uC to check and process all application-threads' work queues.

Atomic operation, "CMPXCHNG8B", is a required instruction to use if multiple application threads are mapped to same doorbell or same doorbell is virtualized via KMD between multiple applications. The latter part refers to a case where KMD removes a doorbell without letting the application know about it. If there is no multiple thread or virtualization case for doorbells, simple memory operations are suffice to operate with doorbells.

Doorbells and Lock

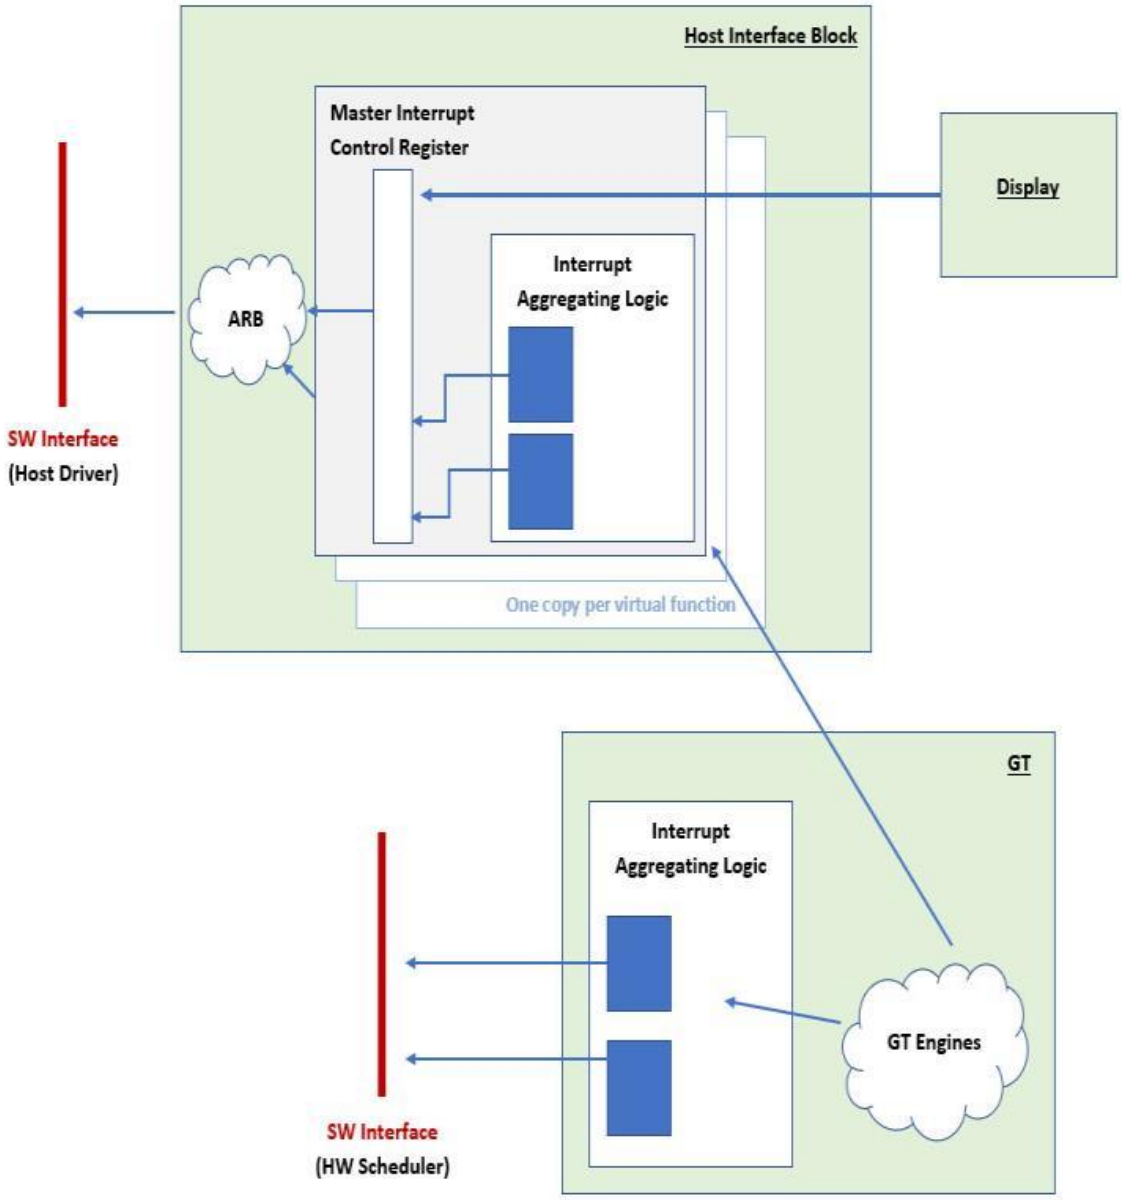
The fact that doorbell block is capable of generating accesses to IDI, it will have to be involved in LOCK process. The impact has to be looked in two different operational modes:

Interrupts Overview:

The Graphics device is comprised of a number of independent engines that can be invoked to execute workloads. Engines communicate status primarily through interrupts. The Graphics device supports two models of scheduling and handling of interrupts:

- Host SW schedules and manages all interrupts
- Scheduling and related interrupts are managed by hardware scheduler (MinIA micro-controller) and host SW manages interrupts not related to scheduling.

The hardware can be configured to work in either of these models. HW scheduling is the preferred mode because it provides best utilization of resources. The figure below shows the high level overview of the interrupt infrastructure.



The interrupt infrastructure is designed to support both of these models. Each engine is allocated a set of interrupt bits that it can set to report events (the number of bits allotted to each engine varies -- most engines are allocated 16bits, some engines which have more events are allocated 32bits). Interrupt messages sent by engines result in interrupt bits being recorded in MMIO registers and an interrupt being generated to the servicing agent (MinIA scheduler or Host SW). The interrupt handler determines the source of the interrupt (by reading registers) and then processes the interrupts. Processing interrupts involves reading the interrupt status register, performing the operations for handling the interrupt and indicating completion of handling by writing to registers (clear).

When using the HW scheduler, the scheduling related interrupts are directed to the MinIA scheduler.

GT Engine Interrupts:

Within GT, engines are categorized into different engine classes and instances. An engine class is used to differentiate between engines that perform different functions (Copy, Render, VideoDecode, VideoEncode, etc). A product may have a number of instances of a specific engine class e.g.: GT2 has 2 instances of VD, GT3 has 4 instances of VD, etc. The following table lists various engine classes as well as instances within each class.

Engine Class	Engine Instance Name	ClassID[2:0]	InstanceID[5:0]
Render	RCS	0	0
Video Decode	VCS0-N	1	0-N
Video Enhancement Engine	VECS0-N/2	2	0-N/2
Copy Engine	BCS	3	0
Other	GuC	4	0
	GTPM	4	1
	WDOAPerf	4	2
	SCTRG	4	3
	KCR	4	4
	Gunit	4	5
	CSME	4	6
Compute Engine	CCS0-N	5	0-N
Reserved		6-7	

Each engine reports up to 16 interrupts to interrupt handling logic. Source identification data is included in interrupt messages to interrupt aggregating logic, i.e. when reporting an interrupt to either host or graphics firmware, the generating engine must identify itself. 16 bits of identification is sent along with interrupt data, and comprises Engine Class ID, Instance ID and Virtual Function Number. Interrupt bit definition varies per engine class, these are listed in the Bspec in the Global/ section.

Format of interrupt message:

Bit Fied	Purpose
[31:30]	Reserved
[29:27]	VF ID
[26]	Reserved
[25:20]	Instance ID

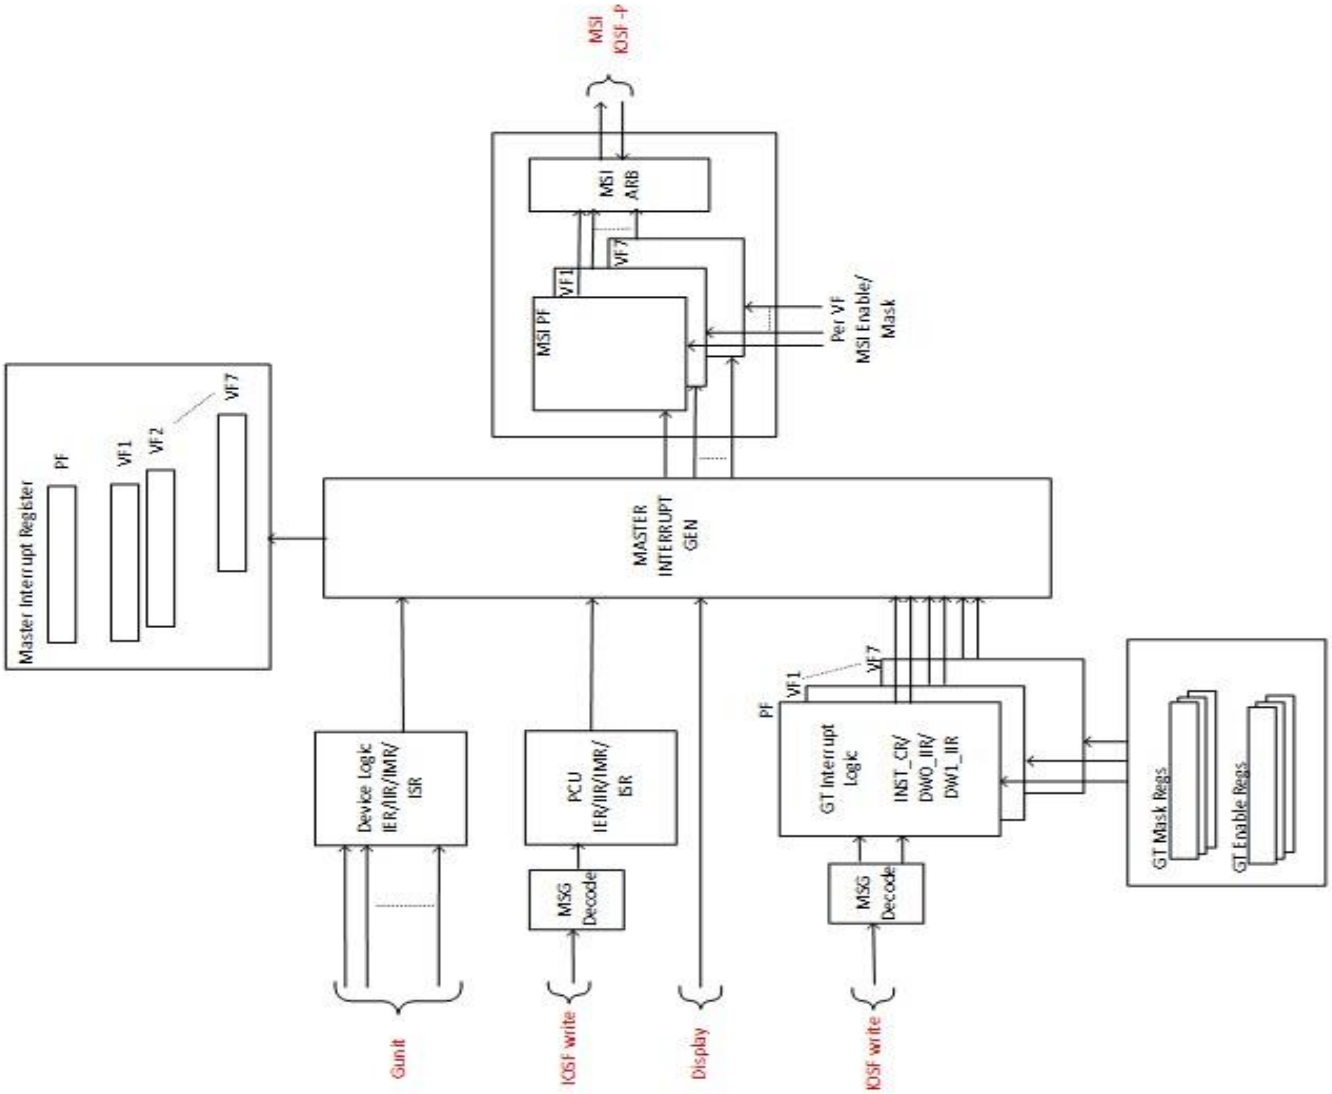
[19]	Reserved
[18:16]	Engine Class ID
[15:0]	Interrupt data

Hardware Scheduler/MinIA SW Interface

Graphics interrupts to scheduling firmware are delivered as two unique vector values. Each vector accounts for 32 graphics engines. Firmware processes each of two groups of graphics engines independently.

Service routines are independent for the two interrupt vectors presented to the MinIA firmware.

Host SW Interface



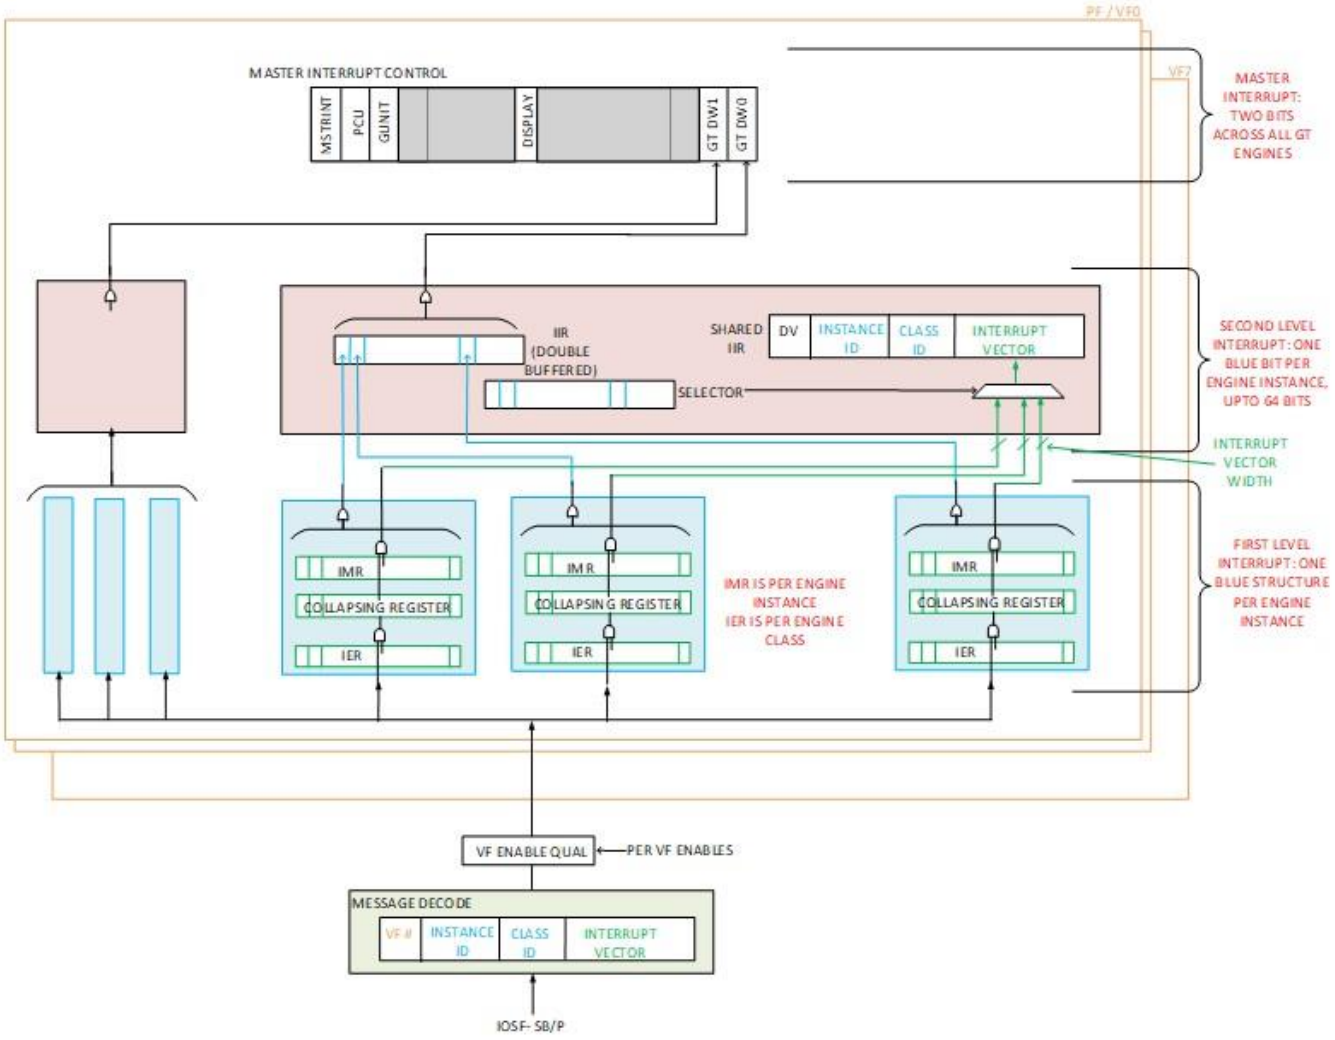
Interrupts to Host are delivered via a Primary Interrupt Control Register. Graphics interrupts use 2 bits in the Primary Interrupt Control Register. In addition, interrupt events from Display are also represented in the Primary Interrupt Control Register. Multiple copies of Primary Interrupt Control Register exist, one for every virtual machine in the system.

Interrupt bits in the Primary Interrupt Control Register are Read-Only bits, and are level indications that a second level interrupt is present (As seen earlier, second level interrupts per client are OR-ed together. When the second level IIR is cleared, the bit represented will be 0.). An interrupt is sent to driver whenever bits are set in the Primary Interrupt Control Register and the Enable bit is also set.

As a result of this interrupt, SW first resets the Primary Control Enable bit. SW then reads the Primary Interrupt Control register into a local variable, and works off this local variable to service interrupts. Once all lower level interrupts have been serviced, SW writes the Primary Interrupt Control register to set the Primary Control Enable bit.

Interrupt Aggregating Logic

A hierarchical interrupt status infrastructure is provided to efficiently determine the source of the interrupt. The first level of interrupts is generated by GT Engines. Interrupt handling logic accumulates these interrupts from the various engines, and organizes it as a single bit per engine in a second level. 32 bits of second level interrupts are OR-ed together to generate a DW-level interrupt event for up to 32 engines. Two such events are used to provide support for up to 64 GT engines. When communicating with the MinIA, these events are mapped to two unique interrupt vectors in the MinIA LAPIC. When communicating with host driver, these events form two bits of the Primary Interrupt Control Register as marked in the picture.



First Level Interrupt Bits:

When an interrupt event comes into the interrupt handling logic, it is AND-ed with a per-Engine Enable register (IER). Only enabled events make forward progress. Disabled events are simply dropped by the interrupt handling logic. [Note that multiple instances of the same engine type (except those in the 'Other' Engine Class) share the same Enable register.]

Enabled interrupts are logged in a per-instance, non-SW readable Collapsing Register. These events are AND-ed with (the inverse of) a per-Instance Mask Register (IMR). Only unmasked events make forward progress. Masked events remain in the per-Instance Collapsing Register until they are unmasked. [Note that every instance (even of the same engine type) has its own Mask Register.]

Unmasked events in the per-Instance Collapsing Register are OR-ed together to produce a single second level interrupt event.

Second Level Interrupt Bits:

Second level interrupt events are stored in a double buffered IIR structure. A snapshot of events is taken when SW reads the IIR. From the time of read to the time of SW completely clearing the second-level

IIR (to indicate end of service), all incoming interrupts are logged in a secondary storage structure. This guarantees that the record of interrupts SW is servicing will not change while under service.

Bits in the second-level IIR are OR-ed together to generate a DW-level event. The IIR is cleared by writing 1s. If events exist in the secondary storage at the time that the IIR is completely cleared, a second DW-level event will be generated.

Shared IIR, Selector:

Shared IIR and Selector registers are used when SW is in the process of handling reported interrupts. As a result of a GT interrupt (DW-level interrupt), SW reads the second-level IIR register. The read provides an indication of engines needing service. SW must then service engines one at a time by writing a one-hot selection into the Selector Register.

When a selection is made by writing the Selector, interrupt handling logic presents all the unmasked interrupt bits (first level interrupt events) for the selected engine in the Shared IIR, and sets the Data-Valid bit (MSB). SW can then read the Shared IIR and take action for the reported events. SW must clear the Shared IIR by writing 1 to the Data-Valid bit to indicate end of service for the selected engine. This clearing of the Shared IIR Data-Valid bit clears both the Shared IIR as well as the Selector. Note that the Selector data must be one-hot. Selector must not have a bit set that is not set in the second-level IIR at the time of SW read.

SW then repeats the above steps for each bit set in the second-level IIR. Multiple rounds of Selector write-Shared IIR clear may be required to service a DW level interrupt a single time.

Second-level IIR bits are cleared only after individual engines are serviced via the Selector write -Shared IIR clear routine. This clearing can be done after each iteration through the Selector write-Shared IIR clear routine (i.e. one second-level bit cleared after each iteration), or all at once after all engines have been serviced. Second-level IIR bits must not be cleared without first servicing that engine's interrupts via the Selector and Shared IIR registers.

Enable and Mask Registers:

Interrupt aggregating logic includes Enable registers(IER) per Engine Class. Different instances of the same engine class use the same Enable register, except for engines in the 'Other' class. Each instance in the 'Other' class has its own Enable register.

Interrupt aggregating logic also includes Mask registers (IMR). Each engine instance, even within the same Engine Class, has a unique Mask Register.

Enables for Engine classes at the two software interfaces are typically complements of each other.

		Gate Enabled or both the engines go Idle. This will lead to ineffective DOP Clock Gate of Media Sampler. This may happen under following circumstances: • SW didn't submit the workload exercising Media Sampler bracketed between PIPELINE_SELECT with Media Sampler DOP Clock Gate Disable and Enable respectively in a single dispatch. OR • Media Sampler Workload got preempted before PIPELINE_SELECT with Media Sampler DOP Clock Gate Enable is executed. SW may avoid the inefficient Media Sampler DOP Clock Gate Enable by avoiding above mentioned scenarios, i.e • Make workloads accessing Media Sampler non-preemptable and ensure they are bracketed between PIPELINE_SELECT with Media Sampler DOP Clock Gate Disable and Enable respectively. Or • Following a context switch status of Active to Idle for a Media Sampler workload from and engine and while other engine is busy, SW must submit a context (dummy no real workload) to the former to reset the Media Sampler DOP Clock Gate to be Enabled.	
hang	Semi pipelined flush not backpressuring when stencil buffer state is enabling thread dispatch resulting in hang	Issue: Semi pipelined flush not backpressuring when stencil buffer state is enabling thread dispatch. Workaround: An additional pipe control with post-sync = store dword operation would be required.(w/a is to have an additional pipe control after the stencil state whenever the surface state bits of this state is changing).	sku: ALL; stepping_impacted: b0; wa_status: driver_permanent_wa

<tr><td></td><td>dupunit not generating line_pop indication for plane with minimum size</td><td>plane horizontal minimum size in PLANE_SIZE register need to be increased according to the following: 8bpp: 18 16bpp: 10 32bpp,yuv212,yuv216: 6 64bpp: 4 NV12: 20 P010,P012,P016: 12</td><td><table><tr><th>sku</th><th>stepping_impacted</th><th>wa_status</th></tr><tr><td>ALL</td><td>a0</td><td>driver_permanent_wa</td></tr></table></td></tr>
<tr><td>data_corruption, performance</td><td>Sampler power context is not saved/restored</td><td>Issue: Sampler Power Context save operation doesn't work correctly. This means that if driver writes to any of the following offsets (E100, E180, E184, E188, E18C, E190, E194) with non-default values will not be persisted across Render power gating/RC6. There are some cases we already know of where driver is expected/required to write non-default values for correct functional operation and best performance: All E18C[0] E18C[15] In addition to these, more cases may be identified later where driver wants/needs to program these registers with non-default values and needs to have that programming be restored after render/RC6 power gating. Workaround: KMD to configure RC6 WA BB for RCS (CTX_WA_PTR) if not already enabled; allocate buffer to contain the commands and ensure it is pinned in GGTT. In the RC6 WA BB, include LRI command that writes to any offsets which require non-default values. More specifically, if KMD programs any of the 7 offsets identified above during driver boot and/or after engine reset, those same offset/value pairs must also include that offset/value in an LRI command in the RC6 WA BB for RCS. Note that all 7 of these offsets are masked registers (upper 16b mask; lower 16b value)- driver only needs to enable the mask bits</td><td><table><tr><th>sku</th><th>stepping_impacted</th><th>wa_status</th></tr><tr><td>ALL</td><td>a0</td><td>driver_permanent_wa</td></tr></table></td></tr>

data_corruption, performance	Sampler power context is not saved/restored	Issue: Sampler Power Context save operation doesn't work correctly. This means that if driver writes to any of the following offsets (E100, E180, E184, E188, E18C, E190, E194) with non-default values will not be persisted across Render power gating/RC6. There are some cases we already know of where driver is expected/required to write non-default values for correct functional operation and best performance: All E18C[0]: E18C[15] In addition to these, more cases may be identified later where driver wants/needs to program these registers with non-default values and needs to have that programming be restored after render/RC6 power gating. Workaround: KMD to configure RC6 WA BB for RCS (CTX_WA_PTR) if not already enabled; allocate buffer to contain the commands and ensure it is pinned in GGTT. In the RC6 WA BB, include LRI command that writes to any offsets which require non-default values. More specifically, if KMD programs any of the 7 offsets identified above during driver boot and/or after engine reset, those same offset/value pairs must also include that offset/value in an LRI command in the RC6 WA BB for RCS. Note that all 7 of these offsets are masked registers (upper 16b mask; lower 16b value)- driver only needs to enable the mask bits for the specific bits it wants to program to non-default value (e.g. for the value for E18C could be 0x1001_1001 (e.g. mask bits 31 & 16 set to allow the values in bit 15 & 0 to take).	<table><tr><th>sku</th><th>Stepping_impacted</th><th>wa_status</th></tr><tr><td>ALL</td><td>a0</td><td>driver_permanent_wa</td></tr></table>

other	PSD RTL bug caught through UVM: disp_reg_addr going to X (PSD_REG_ERR) instead of R67 phase	Corruption can exist in dual-simd8 threads if if R66-R71 is the first phase after R1. This scenario might happen if experimenting with "remove BC" kernel. Enable any phase from R3-R65 to prevent the issue.	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
data_corruption	Corruption may occur with the surface formats B5G5R5X1_UNORM and B5G5R5X1_UNORM_SRGB if Color Blend is enabled	Errata: Corruption may occur with the surface formats B5G5R5X1_UNORM and B5G5R5X1_UNORM_SRGB if Color Blend is enabled.	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
hang	Hull Shader Control and Header Fifo in TRG going out of sync results in hang	Please insert 3D State HS before every 3D primitive that has HS enabled	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa

impact	title	bspec_wa_details	sku_impact
other	Display combo PHY DPLL and thunderbolt PLL fractional divider error	Display DPLL and TBT PLL fractional divider value is shifted when reference is 38.4 MHz, giving slightly incorrect frequencies. Workaround when reference is 38.4 MHz, divide by 2 the value programmed into registers DPLL*_CFGCR0 and TBTPLL_CFGCR0 field DCO Fraction. Example, original DCO Fraction value of 0x7000h must be divided to 0x3800h.	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
hang	With pixel scoreboard disabled, PSS is creating an extra thread with no slotquads loaded when it sees an FC64 8x8 with a different topology have an overlapping X/Y with two already committed partial threads	When SIMD32 is enabled, do not disable pixel scoreboard. In other words, 3DSTATE_PS Bitgroup5[21] = 0 when 3DSTATE_PS Bitgroup5[2] = 1	sku: ALL; Stepping_impacted: b0; wa_status: driver_permanent_wa
hang	Hang can occur on VS UAV write when TE-DOP clk gating is enabled	Set Tessellation DOP Gating Disable via bit [19] in the ThreadMode Register [0x020A0]. eg: 0x020A0[19]=0x1	sku: ALL; Stepping_impacted: b0; wa_status: driver_permanent_wa
other	PSD is indicating the first payload phase as null for PSD_REG_P_BARY_PLANE phase	Ensure that for a PS thread dispatch (3DSTATE_PS_EXTRA[31]), when any one of the bits of 3DSTATE_PS_EXTRA[21:19] is set (requesting Z, W, BARY P/NP planes), we must have at least one of the following bits set - 3DSTATE_WM_BODY BitGroup0 [16:11] (Bary Interpolation Modes) 3DSTATE_PS_EXTRA[24] : Pixel Shader uses source Z 3DSTATE_PS_EXTRA[23]: Pixel Shader uses source W 3DSTATE_PS_EXTRA[18]: Pixel Shader uses Subsample Offsets 3DSTATE_PS_EXTRA[1:0]: Pixel Shader uses Coverage Mask 3DSTATE_PS BitGroup5 [4]: Position X/Y Offset	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
data_corruption	Media compression: Decode output writes sometimes sends data as uncompressed but doesn't properly update tile compression status to match, resulting in corruption when data is consumed later	Compression Control Surface should be cleared for destination buffers at the start of the batch buffer for MFX codecs.	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa

impact	title	bspec_wa_details	sku_impact
hang	CSB data in hw status page may be stale when read out by SW (memory ordering for CS write vs engine interrupt delivery)	Driver initializes CSB data[0...11] with -1 during GPU initialization; - When driver receives the interrupt, it will try to read out the value of every new CSB data, if the value is -1, driver will reread it continuously in 50us until the value is not equal to -1; - After getting the value of every new CSB data, driver will write -1 back into current CSB data offset position; - If the valid value could not be read out in 50us, one warning will be given;	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
performance	dp panel will flicker when system idle at desktop with specific background picture	WA: The driver needs to program the FBC_STRIDE (0x43228) and enable the override stride once. The override stride should be programmed with : Compressed buffer seg stride (in CLs) = ceiling[(at least plane width in pixels * 4 * 4) / (64 * compression limit factor)] + 1 If the CFB size computed by: CFB size (in bytes) = Compressed buffer seg stride * Ceiling(MIN(FBC compressed vertical limit/4, plane vertical source size/4)) * 64, will not fit into the memory allocated to FBC, then driver will need to use a more aggressive compression limit factor.	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
security	MI_FORCE_WAKEUP and engine reset happen at almost same time, then hang can occur	Prior to doing a reset, SW/FW must ensure command streamer is stopped. Setting both the ring stop and preparser enable bit in the below registers will cause the command streamer to halt. Note preparser is only enabled for RCS and CCS command streamers but bit exists in all CS's. MI_MODE set bit 8 GFX_MODE set bit 10	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
data_corruption	3DMark - Firestrike - corruption in OOTB run	WA: Program maximum of 1536 handles for GS.	sku: ALL; Stepping_impacted: a0; wa_status: driver_permanent_wa
hang	Panel Flicker after press F11 or Alt+Tab switch tasks under system.	Corruption seen when FBC is first enabled. After setting the FBC enable, wait for the next start of vblank, then write the plane 1A surface address register.	sku: ALL; Stepping_impacted: b0; wa_status: driver_permanent_wa

impact	title	bspec_wa_details	sku_impact
data_corruption	Page Fault when small number of pixels using Sampler Feedback are rendered	Any kernel that contains AMFS evaluate (WriteSamplerFeedback) operations must issue two sampler cache flush messages after all evaluate operations are sent and before the kernel EOT message. The first sampler cache flush message must have a zero-length return. This is used to signal EOT to the AMFS unit. The second sampler cache flush message must have a non-zero-length return. This is used to block the kernel EOT until all AMFS operations are flushed out of the sampler. Failure to do both sampler cache flush messages can result in HW hangs and/or spurious page faults.	<table><tr><th>sku</th><th>Stepping_impacted</th><th>wa_status</th></tr><tr><td>ALL</td><td>b0</td><td>driver_permanent_wa</td></tr></table>

Intel® Iris® Xe and UHD Graphics Open Source

Programmer's Reference Manual

For the 2020-2021 11th Generation Intel Xeon®, Core™, Celeron®, Pentium® Gold Processors based on the "Tiger Lake" Platform

Volume 2a: Command Reference: Instructions

October 2023, Revision 2.0

Notices and Disclaimers

Intel technologies may require enabled hardware, software or service activation.

No product or component can be absolutely secure.

Code names are used by Intel to identify products, technologies, or services that are in development and not publicly available. These are not "commercial" names and not intended to function as trademarks

Customer is responsible for safety of the overall system, including compliance with applicable safety-related requirements or standards.

No license (express or implied, by estoppel or otherwise) to any intellectual property rights is granted by this document, with the sole exceptions that a) you may publish an unmodified copy and b) code included in this document is licensed subject to Zero-Clause BSD open source license (0BSD). You may create software implementations based on this document and in compliance with the foregoing that are intended to execute on the Intel product(s) referenced in this document. No rights are granted to create modifications or derivatives of this document.

The products described may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

You may not use or facilitate the use of this document in connection with any infringement or other legal analysis concerning Intel products described herein. You agree to grant Intel a non-exclusive, royalty-free license to any patent claim thereafter drafted which includes subject matter disclosed herein.

Intel disclaims all express and implied warranties, including without limitation, the implied warranties of merchantability, fitness for a particular purpose, and non-infringement, as well as any warranty arising from course of performance, course of dealing, or usage in trade.

Intel may make changes to specifications and product descriptions at any time, without notice. Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined". Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them. The information here is subject to change without notice. Do not finalize a design with this information.

3DPRIMITIVE

3DPRIMITIVE

Source: RenderCS

Length Bias: 2

The 3DPRIMITIVE command is used to submit 3D primitives to be processed by the 3D pipeline. Typically the processing results in rendering pixel data into the render targets, but this is not required.
The parameters passed in this command are forwarded to the Vertex Fetch function. The Vertex Fetch function will use this information to generate vertex data structures and store them in the URB. These vertices are then passed down the 3D pipeline.

Programming Notes

If the threads spawned by this command are required to observe memory writes performed by threads spawned from a previous command, software must precede this command with a command that performs a (preferably pipelined) memory flush (e.g., 3D_PIPECONTROL).

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode
	28:27	**Command SubType** Default Value: 3h GFXPIPE_3D Format: OpCode
	26:24	**3D Command Opcode** Default Value: 3h 3DPRIMITIVE Format: OpCode
	23:16	**3D Command Sub Opcode** Default Value: 0h 3DPRIMITIVE Format: OpCode
	15	**Reserved**
	14	**Reserved** Access: RO Format: MBZ
	13	**Reserved** Access: RO Format: MBZ
	12	**POSH Enable** POSH functionality is enabled for this 3DPRIMITIVE command when this bit is set. When executed from the POCS command stream, the 3DPRIMITIVE command is processed and visibility information is recorded. When subsequently executed from the RCS command stream, the previously-recorded visibility information is used to optimize the

processing for this 3DPRIMITIVE command.
Setting this bit will also (temporarily -- for the 3DPRIMITIVE command) inhibit modification of the following statistics counters when the 3DPRIMITIVE command is executed from the RCS command stream, even if these statistics counters are enabled via VF/VS state. This is done to prevent RCS from double-counting statistics that have already been counted by POCS.

- IA_VERTICES_COUNT
- IA_PRIMITIVES_COUNT
- VS_INVOCATION_COUNT

When this bit is clear, this 3DPRIMITIVE command is ignored by the POCS command stream, and when executed in the RCS command stream the command is processed without use of visibility information (as none will have been recorded by the POCS command stream) and with statistics counted as specified by VF/VS state.

Programming Notes

This bit must be clear (POSH disabled) when any one of the following conditions are met:

- A topology type other than: 3DPRIM_TRILIST, 3DPRIM_TRISTRIP, 3DPRIM_TRISTRIP_REVERSE
- UAV Coherency Required and/or Accesses UAV set in 3DSTATE_VS
- Tessellation enabled
- Geometry Shader enabled
- StreamOut enabled

For each 3DPRIMITIVE command that SW submits to the POCS command stream with POSH enabled, SW shall also submit an identical 3DPRIMITIVE command with POSH enabled to the RCS command stream, in the same sequence as submitted to the POCS command stream. In addition to the parameters passed in the 3DPRIMITIVE command fields, the following states shall also match:

- 3DSTATE_VF: States controlling cut index processing must match
- For RANDOM indexing, the Index Buffer states must match

11 **Extended Parameters Present**

Format:	Boolean

If true, three additional DWords containing XP0, XP1 and XP2 parameters are included in this command. Depending on the setting of Indirect Parameter Enable, XP0-2 parameters (sourced either from the inline XP0-2 DWords or indirectly from the 3DPRIM_XP0-2 registers) are passed to the VF stage as possible sources for VF SGV insertion.
If false, XP0-2 DWords are not included in this command and instead XP0-2 values default to zero if enabled as sources in VF SGV insertion.

10 **Indirect Parameter Enable**

Format:	Enable

If set, the values in DW 2-5 are ignored and replaced by the current values of the corresponding 3DPRIM_xxx MMIO registers:

- 3DPRIM_VERTEX_COUNT (instead of DW2: VertexCountPerInstance)
- 3DPRIM_START_VERTEX (instead of DW3: StartVertexLocation)
- 3DPRIM_INSTANCE_COUNT (instead of DW4: InstanceCount)
- 3DPRIM_START_INSTANCE (instead of DW5: StartInstanceLocation)
- 3DPRIM_BASE_VERTEX (instead of DW6: BaseVertexLocation)

Indirect Parameter Enable and End Offset Enable shall not be ENABLED at the same time, or behavior is UNDEFINED.

If set and Extended Parameters Present is true, the current contents of the 3DPRIM_XP0-2 MMIO registers are passed to the VF stage as possible sources for VF SGV insertion and the Extended Parameter 0-2 values included in this command are ignored.

9 **UAV Coherency Required**

Format:	U1

SW will be required to set this bit if there is the possibility of sharing a UAV from a previous 3DPRIMITVE command. If set, this command may cause a flush due to UAV coherency requirements. If none of the shaders have UAV access enabled, then this bit is ignored.

8 **Predicate Enable**

Format:	Enable

If set, this command is executed (or not) depending on the current value of the MI Predicate internal state bit. This command is ignored only if PredicateEnable is set and the Predicate state bit is 0.

7:0 **DWord Length**

Format:	=n

Value	Name	Programming Notes	Exists If
5h	5		[Extended Parameter Enable] == 'false'
8h	8 **[Default]**	When Extended Parameter Enable is true, three Dwords containing Extended Parameter 0-2 shall be included in this command and the DWord Length field set to account for these additional DWords.	[Extended Parameter Enable] == 'true'

1 31:10 **Reserved**

Access:	RO

		Format: MBZ
	9	**End Offset Enable** Format: Enable If set, the Vertex Count Per Instance field is IGNORED, and the 3DPRIM_END_OFFSET register is used to indirectly specify the vertex count by defining the amount of valid data in VB0. The following restrictions apply: • VB0 must be enabled for use • VertexAccessType = SEQUENTIAL • Start Vertex Location = 0 • Start Instance Location = 0 • Base Vertex Location = 0 Vertices are output until EndOffset is reached or exceeded in VB0. If EndOffset is reached or exceeded within the data associated with a vertex, that vertex is considered incomplete and will not be output. Partial objects will be discarded (as is normally done). If clear, End Offset is ignored. Indirect Parameter Enable and End Offset Enable must not be ENABLED at the same time, or behavior is UNDEFINED.
	8	**Vertex Access Type** This field specifies how data held in vertex buffers marked as VERTEXDATA is accessed by Vertex Fetch. Value / Name / Description: 0h / SEQUENTIAL / VERTEXDATA buffers are accessed sequentially Required if End Offset Enable is ENABLED. 1h / RANDOM / VERTEXDATA buffers are accessed randomly via an index obtained from the Index Buffer.
	7:6	**Reserved** Access: RO Format: MBZ
	5:0	**Primitive Topology Type** Format: 3D_Prim_Topo_Type This field specifies the topology type of 3D primitive generated by this command. Note that a single primitive topology (list/strip/fan/etc.) can contain a number of basic objects (lines, triangles, etc.). This field is ignored. The topology type is specified via the 3DSTATE_VF_TOPOLOGY command.
2	31:0	**Vertex Count Per Instance** Format: U32

3DPRIMITIVE

		This field specifies how many vertices are to be generated for each instance of the primitive topology. If End Offset Enable is clear: Format = U32 count of vertices Range = [0, 2^32-1] (upper limit probably constrained by VB size)Ignored if End Offset Enable or Indirect Parameter Enable is ENABLED. **Programming Notes** • This per-instance value should specify a valid number of vertices for the primitive topology type. E.g., for 3DPRIM_TRILIST_ADJ, this field should specify a multiple of 6 vertices. However, in cases where too few or too many vertices are provided, the unused vertices will be silently discarded by the pipeline. • A 0 value is this field effectively makes the command a 'no-operation'.
3	31:0	**Start Vertex Location** Format: U32 This field specifies the "starting vertex" for each instance. This allows skipping over part of the vertices in a buffer if, for example, a previous 3DPRIMITIVE command had already drawn the primitives associated with the earlier entries. For SEQUENTIAL access, this field specifies, for each instance, a starting structure index into the vertex buffers For RANDOM access, this field specifies, for each instance, a starting index into the Index Buffer. **Programming Notes** • Access of any data outside of the valid extent of a vertex or index buffer will return the value 0 (i.e., appears as if the data stored at the invalid location was 0). • Must be set to 0 if End Offset Enable is ENABLED. • Ignored if Indirect Parameter Enable is ENABLED
4	31:0	**Instance Count** Format: U32 This field specifies the number of instances by which the primitive topology is to be regenerated. A value of 0 indicates "no instances" (no-op operation). A value of 1 effectively specifies "non-instanced" operation, though vertex buffers will still be used to provide instance data, if so programmed. Ignored if Indirect Parameter Enable is ENABLED. **Value** | **Name** [0, FFFFFFFFh] |
5	31:0	**Start Instance Location** Format: U32 This field specifies the "starting instance" for the command as an initial structure index into Vertex Buffers for vertex elements with InstancingEnable set. Subsequent instances will access sequential instance data structures, as controlled by the Instance Data Step Rate.

		Programming Notes • Access of any data outside of the valid extent of a vertex or index buffer will return the value 0 (i.e., appears as if the data stored at the invalid location was 0). • Must be set to 0 if End Offset Enable is ENABLED. • Ignored if Indirect Parameter Enable is ENABLED.
6	31:0	**Base Vertex Location** Format: S31 This field specifies a signed bias to be added to values read from the index buffer. This allows the same index buffer values to access different vertex data for different commands. This field applies only to RANDOM access mode. This field is ignored for SEQUENTIAL access mode, where there Start Vertex Location can be used to specify different regions in the vertex buffers. **Programming Notes** • Access of any data outside of the valid extent of a vertex or index buffer will return the value 0 (i.e., appears as if the data stored at the invalid location was 0). • Must be set to 0 if End Offset Enable is ENABLED. • Ignored if Indirect Parameter Enable is ENABLED.
7 **Exists if:** [Extended Parameters Present] == TRUE	31:0	**Extended Parameter 0** Format: U32 If Indirect Parameter Enable is not set, this field specifies a U32 XP0 parameter value to be passed to the VF stage as a possible source for SGV insertion. If Indirect Parameter Enable is set, this field is ignored.
8 **Exists if:** [Extended Parameters Present] == TRUE	31:0	**Extended Parameter 1** Format: U32 If Indirect Parameter Enable is not set, this field specifies a U32 XP1 parameter value to be passed to the VF stage as a possible source for SGV insertion. If Indirect Parameter Enable is set, this field is ignored.
9 **Exists if:** [Extended Parameters Present] == TRUE	31:0	**Extended Parameter 2** Format: U32 If Indirect Parameter Enable is not set, this field specifies a U32 XP2 parameter value to be passed to the VF stage as a possible source for SGV insertion. If Indirect Parameter Enable is set, this field is ignored.

3DSTATE_3D_MODE

3DSTATE_3D_MODE

Source: RenderCS

Length Bias: 2

This command is general 3D programming state that can be shared from the top to bottom of the pipeline.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode
	28:27	**Command SubType** Default Value: 3h GFXPIPE_3D Format: OpCode
	26:24	**3D Command Opcode** Default Value: 1h GFXPIPE_NONPIPELINED Format: OpCode
	23:16	**3D Command Sub Opcode** Default Value: 1Eh 3DSTATE_3D_MODE Format: OpCode
	15:8	**Reserved** Access: RO Format: MBZ
	7:0	**DWord Length** Default Value: 1h Excludes DWord (0,1) Format: =n
1	31:16	**Mask Bits 1** Format: Enable[16] This field is the mask bits for the state bits below. This is a bit wise mask where the bit number-16 is the value of the corresponding bit being masked in the same data word. For example, if you want to update state for bits 3:2 then bits 19:18 must be set.
	15:11	**Reserved** Access: RO Format: MBZ
	10	**Reserved** Access: RO Format: MBZ

3DSTATE_3D_MODE

9 Float Blend Optimization Disable

Value	Name	Description
0h	**[Default]**	Enables blend optimization for floating point RTs.
1h		Disables blend optimization for floating point RTs.

8 Reserved

Access:	RO
Format:	MBZ

7 Reserved

Access:	RO
Format:	MBZ

6 Slice Hashing Table Enable

Format:	Enable

This field enables the use of indirect state **SLICE_HASH_TABLE** programmed via **3DSTATE_SLICE_HASH_STATE_POINTER**.

Value	Name	Description
0h	Disable **[Default]**	Slice Hashing is based on default lookup tables with the following function (X+Y) % total_enabled_subslices % enabled_slices
1h	Enable	Slice Hashing is via SLICE_HASH_TABLE from 3DSTATE_SLICE_HASH_STATE_POINTER[total_enabled_subslices-4]

5 Subslice Hashing Table Enable

Format:	Enable

This field enables the use of the Subslice Hashing Mode table programmed via **3DSTATE_SUBSLICE_HASH_TABLE**.

Value	Name	Description
0h	Disable **[Default]**	Subslice Hashing is computed
1h	Enable	Subslice Hashing is via 3DSTATE_SUBSLICE_HASH_TABLE

4 3D Scoreboard Hashing Mode

Value	Name	Description
0	Scoreboard address calculation optimized for Subslice Hashing Mode **[Default]**	Before scoreboard address calculations one address bit will be removed to increase the efficiency of the scoreboard.
1	Scoreboard address calculation not optimized	All address bits used when calculating scoreboard address.

Programming Notes
When **Subslice Hashing Table Enable** and table entries do not contain a checkerboard pattern for each subslice, then optimizing for **Subslice Hashing Mode** may result in reduced performance due to increased false dependencies.

3DSTATE_3D_MODE

3:2 Subslice Hashing Mode

This field is not used by the hardware. Hardware performs 16x16 hashing only.

1:0 Cross Slice Hashing Mode

Format:	U2

Value	Name	Description	Programming Notes
0h	Normal Mode **[Default]**	num_slices > 1 : 16x16 Hashing enabled num_slices == 1: No cross slice hashing	
1h	Cross Slice Hashing Disable	Disables the cross slice hashing	
2h	Reserved	Reserved	
3h	32X32 hashing	32X32 pixel hashing across slices	This setting must be used when sub-slice hashing mode is 16x16 and num_slices > 1

Programming Notes

Cross slice hashing disable must be used when num_slices > 1, normal mode of operation when num_slices > 1 will be to use either 16x16 Hashing or 32x32 Hashing.
A stalling flush is required before changing the value of this field. This is to make sure the entire pipeline is drained.

2 31:16 Mask Bits 2

Format:	Enable[16]

This field is the mask bits for the state bits below. This is a bit wise mask where the bit number-16 is the value of the corresponding bit being masked in the same data word. For example, if you want to update state for bits 6:0 then bits 22:16 must be set.

15:10 Reserved

Access:	RO
Format:	MBZ

9:7 Reserved

Access:	RO
Format:	MBZ

6:0 AMFS MOCS

Format:	MEMORY_OBJECT_CONTROL_STATE

Programming Notes

SW must explicitly program AMFS_FLUSH using PIPE_CONTROL command prior to changing this field. SW must also explicitly flush DC cache flush if the setting of this field is changing from cacheable to non-cacheable in L3.

3DSTATE_AA_LINE_PARAMETERS

3DSTATE_AA_LINE_PARAMETERS

Source: RenderCS

Length Bias: 2

The 3DSTATE_AA_LINE_PARAMS command is used to specify the slope and bias terms used in the improved alpha coverage computation (specifically for DX WHQL compliance). Note that in these devices the coverage values passed to PS threads are full U0.8 values, versus where U0.4 values are passed.

Workaround

Workaround : This command must be followed by a PIPE_CONTROL with CS Stall bit set.,

DWord	Bit	Description

3DSTATE_CHROMA_KEY

3DSTATE_CHROMA_KEY

Source: RenderCS, ComputeCS

Length Bias: 2

The 3DSTATE_CHROMA_KEY instruction is used to program texture color/chroma-key key values. A table containing four set of values is supported. The ChromaKey Index sampler state variable is used to select which table entry is associated with the map. Texture chromakey functions are enabled and controlled via use of the ChromaKey Enable texture sampler state variable. Texture Color Key (keying on a paletted texture index) is not supported.

DWord	Bit	Description

	29:0	**Reserved** Access: RO Format: MBZ

3DSTATE_CHROMA_KEY

2	31:0	**ChromaKey Low Value** This field specifies the "low" (minimum) value of the chroma key range. Texel samples are considered "matching the key" if each component of the texel falls within the (inclusive) chroma range. See ChromaKey High Value for further format, programming info.
3	31:0	**ChromaKey High Value** This field specifies the "high" (maximum) value of the chroma key range. Texel samples are considered "matching the key" if each component of the texel falls within the (inclusive) chroma range.

Programming Notes

ChromaKey values are specified using 8-bit channels. When using surface formats with less than 8 bits per channel, the device will expand channels by replicating the required number of MSBs into the LSBs of each channel. Software must account for this conversion when it programs Chromakey Low/High Values (e.g., by performing the same replication).

For channels that do not exist in the actual surface (e.g., Alpha channel for non-ARGB maps), software must explicitly program full range high/low values (High=FFh, Low=0h for formats using unsigned chroma key values, High=7Fh, Low=FFh for formats using sign magnitude chroma key values) in order to effectively remove the comparison of that field from the ChromaKey function.

For channels in SNORM format in the surface format, the value in the high/low value for that channel is interpreted in sign magnitude format. Negative zero value is not supported (use positive zero instead). For channels with mixed UNORM/SNORM formats (i.e. R5G5_SNORM_B6_UNORM), the ChromaKey is programmed as if all channels are SNORM.

YUV ChromaKey will use an interpolated chrominance value from the map for comparison to the chroma key values for those texels without chrominance due to downsampling. The chrominance value used is the average of values to the left and right of the texel in question.

It is UNDEFINED to program any component of the ChromaKey High Value to be less than the corresponding component of ChromaKey Low Value.

Format = interpreted according to associated texel format "class":

Only the surface formats listed as supported for chroma key in the surface formats table can be used with this feature. Use of any other surface format with chroma key enabled is UNDEFINED.

Surface Format	31:24	23:15	16:8	7:0
ARGB and BC (DXT) formats	A	R	G	B
YCrCb formats	A	Cr	Y	Cb

3DSTATE_CLEAR_PARAMS

3DSTATE_CLEAR_PARAMS

Source: RenderCS

Length Bias: 2

This command defines the depth clear value delivered as a pipelined state command. However, the state change pipelining isn't completely transparent (see restriction below).

HW will internally manage the draining pipe and flushing of the caches when this command is issued. The PIPE_CONTROL restrictions are removed.

3DSTATE_CONSTANT_ALL

3DSTATE_CONSTANT_ALL

Source: RenderCS, PositionCS

Length Bias: 2

This instruction species pointers and sizes of data to be fetched from memory and loaded as part of the shaders thread payload.

Programming Notes

The programming of enabled buffers is in ascending order where if buffer zero is programmed it will be the first pointer programmed and parsed. Any buffers being omitted must not be programmed.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode
	28:27	**Command SubType** Default Value: 3h GFXPIPE_3D Format: OpCode
	26:24	**3D Command Opcode** Default Value: 0h 3DSTATE_PIPELINED Format: OpCode
	23:16	**3D Command Sub Opcode** Default Value: 6Dh 3DSTATE_CONSTANT_ALL Format: OpCode
	15	**POSH-Enabled Render State Optimization Enable** This bit allows a state command to participate in the POSH-Enabled Render State Optimization function. That function skips over selected commands deemed unnecessary due to the subsequent POSH-Enabled 3DPRIMITIVE command being completely culled by the POSH pipeline. Software shall ensure that the following conditions are met as a prerequisite to setting this bit: 1. The state command is only executed by the Render pipeline. (The bit must be cleared if the state command is executed by the POSH pipeline.) 2. The very next 3DPRIMITIVE command has POSH-Enabled specified. 3. The state programmed is only used by the very next 3DPRIMITIVE command. I.e., following the very next 3DPRIMITIVE command, the relevant state is reprogrammed prior to a subsequent 3DPRIMITIVE command. For improved performance, Software should set this bit if these conditions are met, however Software is not required to do so.

3DSTATE_CONSTANT_ALL

	14:13	**Reserved** Access: RO Format: MBZ
	12:8	**Shader Mask** This bit specifies if the updated pointers are valid for specific shaders. Value / Name: xxxx1b – Vertex Shader Update Enable xxx1xb – Hull Shader Update Enable xx1xxb – Domain Shader Update Enable x1xxxb – Geometry Shader Update Enable 1xxxxb – Pixel Shader Update Enable
	7:0	**DWord Length** Format: =n n = 2b (where b = # of pointers included) Value / Name: 8 – DWORD_COUNT_n **[Default]** [0,8] – 0-4 Pointers
1	31	**Update Mode** If set, pointers that are not valid will retain their value. If clear, then all pointers not valid will be cleared with zero address and zero size. If pointer is valid, then the value of this field is a don't care and the value programmed is always loaded. Value / Name: 0 – Clear pointer and size of non-valid pointers 1 – Retain value of non-valid pointers

3DSTATE_CONSTANT_PS

3DSTATE_CONSTANT_PS

Source: RenderCS

Length Bias: 2

This command sets pointers to the push constants for the PS unit. The constant data pointed to by this command is loaded into the PS unit's push constant buffer (PCB).

Programming Notes

A 3DSTATE_GATHER_PS command must be dispatched along with any 3DSTATE_CONSTANT_PS command when the Gather Pool is enabled within a batch buffer.

The 3DSTATE_CONSTANT_* command is not committed to the shader unit until the corresponding (same shader) 3DSTATE_BINDING_TABLE_POINTER_* command is parsed. For example, the 3DSTATE_CONSTANT_VS command will not fetch the constant buffers from memory and make available to the shader until the 3DSTATE_BINDING_TABLE_POINTERS_VS is parsed by the render command streamer. In case of multiple 3DSTATE_CONSTANT_VS programmed prior to 3DSTATE_BINDING_TABLE_POINTER_VS, only the most recently programmed 3DSTATE_CONSTANT_VS will be committed.
SW must ensure any uncommitted 3DSTATE_CONSTANT_* commands programmed get explicitly committed prior to enabling or disabling the legacy mode.
On usage model of enabling legacy mode is when Resource Streamer is not enabled.

Workaround

The driver must ensure the following case does not occur without a flush to the 3D engine: 3DSTATE_CONSTANT_* with buffer 3 read length equal to zero committed followed by a 3DSTATE_CONSTANT_* with buffer 0 read length not equal to zero committed. Possible ways to avoid this condition include:

- always force buffer 3 to have a non-zero read length
- always force buffer 0 to a zero read length

3DSTATE_DEPTH_BUFFER

3DSTATE_DEPTH_BUFFER

Source: RenderCS

Length Bias: 2

The depth buffer surface state is delivered as a pipelined state packet. However, the state change pipelining isn't completely transparent (see restriction below).

WM HW will internally manage the draining pipe and flushing of the caches when this command is issued. The PIPE_CONTROL restrictions are removed.

Programming Notes

Note for validation teams. If the depth surface is backdoor initialized or written to directly by the CPU, the values placed in the Depth Surface must be within the numeric range of [0.0 ... 1.0] for DirectX and may in the future include +/- max floating-point values; but not +/-Inf, DNORMs or any NaN code.
If the Depth surface is not present, SW must set the Surface Type field to SURFTYPE_NULL

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode
	28:27	**Command SubType** Default Value: 3h GFXPIPE_3D Format: OpCode
	26:24	**3D Command Opcode** Default Value: 0h 3DSTATE_PIPELINED Format: OpCode
	23:16	**3D Command Sub Opcode** Default Value: 5h 3DSTATE_DEPTH_BUFFER Format: OpCode
	15:8	**Reserved** Access: RO Format: MBZ
	7:0	**DWord Length** Format: =n Excludes DWord(0,1) Value: 6h — Name: Excludes Dword (0,1) **[Default]**
1	31:29	**Surface Type** Value: 0h — Name: Reserved — Description: Reserved

1h	SURFTYPE_2D	Defines a 2-dimensional map or array of maps
2h	Reserved	Reserved
3h	SURFTYPE_CUBE	Defines a cube map
4h-6h	Reserved	
7h	SURFTYPE_NULL	Defines a null surface

Programming Notes
The Surface Type of the depth buffer must be the same as the Surface Type of the 1. Render target(s) (defined in SURFACE_STATE), unless either the depth buffer or render targets are SURFTYPE_NULL 2. Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless either the depth buffer or Stencil buffer surf_type are SURFTYPE_NULL. If depth is enabled with 1D render target, depth surface type needs to be set to 2D surface type and height set to 1. For this case only, the Surface Type of the depth buffer can be 2D while the Surface Type of the render target(s) are 1D, representing an exception to a programming note above.

28 **Depth Write Enable**

Format:	Enable

This field enables depth writes to the depth buffer surface. Both this field and the Depth Buffer Write Enable field in DEPTH_STENCIL_STATE must be enabled in order for depth writes to occur.

27 **Null Page Coherency Enable**

Format:	Enable

This field is used for enabling NULL coherency as defined under Tiled Resources.

Value	Name
1	Enable
0	Disable **[Default]**

Programming Notes
SW must enable this bit only if Tiled Resource is enabled

26:24 **Surface Format**

Specifies the format of the depth buffer.

Value	Name
0h	Reserved
1h	D32_FLOAT
2h	Reserved
3h	D24_UNORM_X8_UINT
4h	Reserved
5h	D16_UNORM
6h-7h	Reserved

3DSTATE_DEPTH_BUFFER

23 **Corner Texel Mode**

Format:	Enable

This field, when ENABLED, indicates when a surface is using corner texel-mode for depth surface. This bit changes how the size of each MIP when calculating the offset within a surface.

Value	Name	Description
0h	Disable **[Default]**	Corner Texel mode is not enabled.
1h	Enable	Corner Texel Mode is enabled.

Programming Notes
Corner texel for the depth buffer must be the same as the Surface Type of the 1. Render target(s) (defined in SURFACE_STATE), unless either the depth buffer or render targets are SURFTYPE_NULL 2. Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless either the depth buffer or Stencil buffer surf_type are SURFTYPE_NULL

22 **Hierarchical Depth Buffer Enable**

Format:	Enable

If enabled, indicates that a hierarchical depth buffer is defined.

Programming Notes
If this field is enabled, the Software Tiled Rendering Mode must be NORMAL. This field must be disabled if Early Depth Test Enable is disabled OR if depth buffer surface type is NULL. This field must be disabled if surface type field is SURFTYPE_1D

21 **Depth Buffer Compression Enable**

Format:	Enable

if enabled, indicates that Depth Buffer Compression is Enabled
When thisfield is enabled, Depth Buffer must be initialized via Depth Clear (HZ_OP) when HiZ is enabled. If HiZ is disabled, Depth Buffer must be initialized via full screen primitive with Depth Write enabled and Depth Test Disabled.

Programming Notes
SW must set this bit if the Depth Control surface enable is also set. The depth surface control enable is in Bit[19] of this DWORD.

20 **Reserved**

Access:	RO
Format:	MBZ

19 **Control Surface Enable**

If set to 1, it indicates if the common control surface is present. The read and write transaction opcodes sent by RCZto the fabric are different depending on the control surface. If the control surface is not present, the reads and writes are in legacy mode. If the control surface is present, the reads and write opcodes will be either UNCOMPRESSED_TYP for uncompressible transactions (resolves) or COMPRESSED_TYP for compressible transactions.

Programming Notes
SW must set this bit to "1", if the common control surface is present in the system.

3DSTATE_DEPTH_BUFFER

	18	**Reserved** Access: RO Format: MBZ
	17:0	**Surface Pitch** Format: U18-1 For TileYF and TileYS surfaces, the range is dependent on the Cu parameter (refer to *Memory Data Formats* section for the definition of the Cu parameter depending on the case). The range in bytes is [2^{Cu}-1,262143] -> [(2^{Cu})B,256KB] = [1 tile, 256KB/(2^{Cu}) tiles]
2..3	63:0	**Surface Base Address** Format: VIRTUAL_ADDR[63:0]
4	31	**Reserved** Access: RO Format: MBZ
	30:17	**Height** Format: U14-1 This field specifies the height of the surface. If the surface is MIP-mapped, this field contains the height of the base MIP level.

Value	Name	Description
[7Fh,3FFFFh]		corresponding to [128B, 256KB] also restricted to a multiple of 128B

Programming Notes

The minimum pitch should be calculated based on Cu, Cv, W_L.
The Cu, Cv are the tile constants and $W_L$is the aligned width adjusted for MSAA.
Refer to **2D Surfaces** *to get the Cu, Cv, $W_L$values and Calculations.*
Then use this for pitch formula :
Minimum_pitch =(ceiling((W_0 pixel_size) / (1 « Cu)) *(1 « Cu)) 1 ; //$W_0$is the aligned width for the largest LOD (i.e LOD 0)*
(1 « Cu) = tile width in bytes
(1 « Cv) = tile height in lines

Programming Notes

This field specifies address of the buffer in mapped Graphics Memory. The Depth Buffer can only be mapped to Main Memory (uncached). If the surface is tiled, the base address must conform to the Per-Surface Tiling Alignment. If the buffer is linear, the surface must be 64-byte aligned.
If the buffer is linear, the surface must be 64-byte aligned.

Value	Name	Description	Exists If
[0,16383]	Legal Range	Height of surface - 1 (y/v dimension)	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_2D')
[0,16383]	Legal Range	y/v dimension	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_CUBE')

3DSTATE_DEPTH_BUFFER

Programming Notes

The Height of the depth buffer must be the same as the Height of the
1. render target(s) (defined in SURFACE_STATE), unless Surface Type is SURFTYPE_2D with Depth = 0 (non-array) and LOD = 0 (non-mip mapped) or if SURFACE_STATE_SURFTYPE is NULL.
2.Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless Stencil buffer surf_type is SURFTYPE_NULL

16 **Reserved**

Access:	RO
Format:	MBZ

15 **Reserved**

Access:	RO
Format:	MBZ

14:1 **Width**

Format:	U14-1

This field specifies the width of the surface. If the surface is MIP-mapped, this field specifies the width of the base MIP level. The width is specified in units of pixels.

Value	Name	Description	Exists If
[0,16383]	Legal Range	Width of surface - 1 (x/u dimension)	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_2D')
[0,16383]	Legal Range	Width of surface - 1 (x/u dimension)	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_CUBE')

Programming Notes

The Width specified by this field must be less than or equal to the surface pitch (specified in bytes via the Surface Pitch field). For cube maps, Width must be set equal to Height.
The Width of the depth buffer must be the same as the
1. Width of the render target(s) (defined in SURFACE_STATE), unless Surface Type is SURFTYPE_1D or SURFTYPE_2D with Depth = 0 (non-array) and LOD = 0 (non-mip mapped) or if SURFACE_STATE_SURFTYPE is NULL.
2.Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless Stencil buffer surf_type is SURFTYPE_NULL

0 **Reserved**

Access:	RO
Format:	MBZ

5 31 **Reserved**

Access:	RO
Format:	MBZ

3DSTATE_DEPTH_BUFFER

30:20 **Depth**

Format:	U11-1

This field specifies the total number of levels for a volume texture or the number of array elements allowed to be accessed starting at the Minimum Array Element for arrayed surfaces. If the volume texture is MIP-mapped, this field specifies the depth of the base MIP level.

Value	Name	Description	Exists If
[0,2047]	Legal Range	Number of array elements - 1	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_2D')
[0,0]	Legal Range	Must be zero	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_CUBE')

Programming Notes

The Depth of the depth buffer must be the same as
1. The Depth of the render target(s) (defined in SURFACE_STATE).
2.Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless Stencil buffer surf_type is SURFTYPE_NULL

19 **Reserved**

Access:	RO
Format:	MBZ

18:8 **Minimum Array Element**

Format:	U11

For 2D Surfaces: This field indicates the minimum array element that can be accessed as part of this surface. The delivered array index is added to this field before being used to address the surface. For Other Surfaces This field is ignored

Value	Name	Exists If
[0,2047]	SURFTYPE_2D	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_1D'|Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_2D')

Programming Notes

Minimum array element of the depth buffer must be the same as the Surface Type of the
1. Render target(s) (defined in SURFACE_STATE), unless either the depth buffer or render targets are SURFTYPE_NULL
2. Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless either the depth buffer or Stencil buffer surf_type are SURFTYPE_NULL

7 **Reserved**

Access:	RO
Format:	MBZ

6:0 **Depth Buffer Object Control State**

Format:	MEMORY_OBJECT_CONTROL_STATE

Specifies the memory object control state for the depth buffer.

3DSTATE_DEPTH_BUFFER

6 — 31:30 — Tiled Mode

For Depth Buffer Surfaces: This field specifies the tiled mode. For other surfaces: This field is ignored.

Value	Name	Description
0h	NONE	No tiled modes (TileYf, TileYs). Use Standard TileY
1h	TILEYF	4KB tiled mode
2h	TILEYS	64KB tiled mode
3h	Reserved	

Programming Notes
If **Tile Mode** is not set to TILEMODE_YMAJOR, this field must be set to TRMODE_NONE.

29:26 — Mip Tail Start LOD

Format:	U4

For Sampling Engine, Render Target, and Typed Surfaces: This field indicates which LOD is the first one in the MIP tail if **Tiled Mode** is not TRMODE_NONE. The MIP tail has a different layout than the rest of the surface. Refer to the *Memory Data Formats* section for more details.
For other surfaces: This field is ignored.

Programming Notes
This field must be zero if the **Surface Format** is MONO8. This field is ignored if **Tiled Mode** is TRMODE_NONE unless **Surface Type** is SURFTYPE_1D.
If Tiled Mode is not TRMODE_NONE, this field must be set to ensure that mips within the mip tail do not overlap given the storage algorithms given in the Memory Data Formats section. The following table indicates the maximum size of the mip that is set to be the Mip Tail Start LOD for various cases:

Tiling Mode	Slot Size in Bytes	8-bit Size	16-bit Size	32-bit Size
2D TIleYs 1x	32KB	(128, 256)	(128, 128)	(64, 128)
2D TileYf 1x	2KB	(32, 64)	(32, 32)	(16, 32)

25:6 — Reserved

Access:	RO
Format:	MBZ

5:0 — Reserved

Access:	RO
Format:	MBZ

7 — 31:21 — Render Target View Extent

Format:	U11-1

Value	Name	Description	Exists If
[0,2047]	Legal	Number of array	(Structure[RENDER_SURFACE_STATE][Surface

	Range	elements- 1	Type]=='SURFTYPE_2D')
[0,0]	Legal Range	Must be zero	(Structure[RENDER_SURFACE_STATE][Surface Type]=='SURFTYPE_CUBE')

Programming Notes
Render target View Extent of the depth buffer must be the same as the Surface Type of the 1. Render target(s) (defined in SURFACE_STATE), unless either the depth buffer or render targets are SURFTYPE_NULL 2. Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless either the depth buffer or Stencil buffer surf_type are SURFTYPE_NULL

20 **Reserved**

Access:	RO
Format:	MBZ

19:16 **Surf LOD**

Value	Name
[0-14]	

Programming Notes
Surf LOD of the depth buffer must be the same as the Surface Type of the 1. Render target(s) (defined in SURFACE_STATE), unless either the depth buffer or render targets are SURFTYPE_NULL 2. Stencil buffer (defined in 3DSTATE_STENCIL_BUFFER) unless either the depth buffer or Stencil buffer surf_type are SURFTYPE_NULL

15 **Reserved**

Access:	RO
Format:	MBZ

14:0 **Surface QPitch**

Format:	U17[16:2]

Format: QPitch[16:2]
The interpretation of this field is dependent on **Surface Type** as follows:

- SURFTYPE_2D/CUBE: distance in *rows* between array slices.

Other surface types: field is ignored

Value	Name	Description
[1h,7FFFh]		in multiples of 4 (low 2 bits missing)

Programming Notes
For 2D Surfaces: This field must be set to the same value as the Depth field. For Other Surfaces,

3DSTATE_DEPTH_BUFFER		
		This field is ignored . Refer to Alignment Unit Size for alignment sizes based on MSAA and Depth-format. Software must ensure that this field is set to a value sufficiently large that array slices in the surface do not overlap. Refer to the Memory Data Formats section for information on how surfaces are stored. TYS/TYF QPitch is valid only for 2D array surfaces and represents the tile-padded total number of texels(lines) in a single array slice. Height of each LOD: HL = AlignToTileHeight(MSAA_height_factor * (**height**»L) > 0?**height**»L : 1), where AlignToTileHeight(x) is (ceiling((x) / (1 « Cv)) *(1 « Cv)) Height of all LODs is a sum: H = H0+H1+..Hn, N is number of mip levels. If surface has MIP tail, equation stops at Hn where n=MipTailStartLOD. MipTail is single tile. QPitch is multiple of tile height (1 « Cv) and should be equal or greater H computed above.

3DSTATE_DRAWING_RECTANGLE

3DSTATE_DRAWING_RECTANGLE

Source: RenderCS

Length Bias: 2

The 3DSTATE_DRAWING_RECTANGLE command is used to set the 3D drawing rectangle and related state.

Restriction
When executed in POCS command stream, this programs the drawing rectangle for the SFR stage of the POCS pipeline.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode
	28:27	**Command SubType** Default Value: 3h GFXPIPE_3D Format: OpCode

3DSTATE_DRAWING_RECTANGLE

1 — 31:16 — Clipped Drawing Rectangle Y Min

Format:	U16

Specifies Ymin value of (inclusive) intersection of Drawing rectangle with the Color (Destination) Buffer, used for clipping. Pixels with Y coordinates less than Ymin will be clipped out.

Value	Name
[0,16383]	Device ignores bits 31:30

Programming Notes
This value can be larger than Clipped Drawing Rectangle Y Max. If Ymin>Ymax, the clipped drawing rectangle is null, all polygons are discarded. If Ymin==Ymax, the clipped drawing rectangle is 1 pixel wide in the Y direction.

1 — 15:0 — Clipped Drawing Rectangle X Min

Format:	U16

Specifies Xmin value of (inclusive) intersection of Drawing rectangle with the Color (Destination) Buffer, used for clipping. Pixels with X coordinates less than Xmin will be clipped out.

Value	Name
[0,16383]	Device ignores bits 15:14

Programming Notes
This value can be larger than Clipped Drawing Rectangle X Max. If Xmin>Xmax, the clipped drawing rectangle is null, all polygons are discarded. If Xmin==Xmax, the clipped drawing rectangle is 1 pixel wide in the X direction.

2 — 31:16 — Clipped Drawing Rectangle Y Max

Format:	U16

Specifies Ymax value of (inclusive) intersection of Drawing rectangle with the Color (Destination) Buffer, used for clipping. Pixels with coordinates greater than Ymax will be clipped out.

Value	Name
[0,16383]	Device ignores bits 31:30

Programming Notes
This value can be less than Clipped Drawing Rectangle Y Min. If Ymax<Ymin, the clipped drawing rectangle is null, all polygons are discarded. If Ymin==Ymax, the clipped drawing rectangle is 1 pixel wide in the Y direction.

2 — 15:0 — Clipped Drawing Rectangle X Max

Format:	U16

Specifies Xmax value of (inclusive) intersection of Drawing rectangle with the Color (Destination) Buffer, used for clipping. Pixels with coordinates greater than Xmax will be clipped out.

Value	Name
[0,16383]	Device ignores bits 15:14

3DSTATE_DRAWING_RECTANGLE		
		Programming Notes This value can be less than Clipped Drawing Rectangle X Min. If Xmax<Xmin, the clipped drawing rectangle is null, all polygons are discarded. If Xmin==Xmax, the clipped drawing rectangle is 1 pixel wide in the X direction.
3	31:16	**Drawing Rectangle Origin Y** Format: S15 Range: [-16384,16383] (Bit 31 should be a sign extension) Specifies Y origin of Drawing Rectangle (in whole pixels) relative to origin of the Color Buffer, used to map incoming (Draw Rectangle-relative) vertex positions to the Color Buffer space.
	15:0	**Drawing Rectangle Origin X** Format: S15 Range: [-16384,16383] (Bit 15 should be a sign extension) Specifies X origin of Drawing Rectangle (in whole pixels) relative to origin of the Color Buffer, used to map incoming (Draw Rectangle-relative) vertex positions to the Color Buffer space.

3DSTATE_DS

3DSTATE_DS		
Source:	RenderCS	
Length Bias:	2	
The state used by DS is defined with this inline state packet

1..8	255:0	**HS State Body** Format: 3DSTATE_HS_BODY

3DSTATE_INDEX_BUFFER

3DSTATE_INDEX_BUFFER

Source: RenderCS

Length Bias: 2

This command is used to specify the current IB state used by the VF function. At most one IB is defined and active at any given time. NOTES: The IB must be specified before any RANDOM 3D_PRIMITIVE commands are issued It is possible to have vertex elements source completely from generated ID values and therefore not require any Index Buffer accesses. In this case, VF function will simply ignore the Index Buffer state.

Programming Notes

When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode

3DSTATE_PTBR_FREE_LIST_BASE_ADDRESS

3DSTATE_PTBR_FREE_LIST_BASE_ADDRESS

Source: PositionCS

Length Bias: 2

The 3DSTATE_PTBR_FREE_LIST_BASE_ADDRESS command programmed specifies a 4KB aligned base address to 128KB (2^{16}* 2B) of contiguous memory surface called Free-List memory. This command must be programmed only for POSH pipe and must not be programmed for render pipe. This command is context specific and must be programmed for each of the POSH enabled context. This command gets context save/restored as part of the POSH context.

POSH pipe uses Free-List memory to track the free pages (page offsets from PTBR Page Pool Base Address are stored) available for recording visibility data. Pages get consumed form the Free-List as and when the visibility data is recorded by POSH pipe and pages get added to the Free-List when freed up by the render engine on rendering.

Programming Notes

The Free List Base Address must be set to a valid page if any batch buffer is enabled for the POSH pipe.

3DSTATE_PTBR_PAGE_POOL_BASE_ADDRESS

3DSTATE_PTBR_PAGE_POOL_BASE_ADDRESS

Source: PositionCS

Length Bias: 2

The 3DSTATE_PTBR_PAGE_POOL_BASE_ADDRESS command specifies base address of the PTBR page pool allocated to HW for recording visibility data in POSH Tile Based Rendering Mode (PTBR). The size of the PTBR Page Pool Size is programmed through the MMIO register PTBR_PAGE_POOL_SIZE_REGISTER following this command. SW must always set Page Pool Restart to enabled when programming this command.
This command must be programmed only for POSH pipe and must not be programmed for render pipe. This command is context specific and must be programmed for each of the POSH enabled context. This command gets context save/restored as part of the POSH context. HW context save/restores 3DSTATE_PTBR_PAGE_POOL_BASE_ADDRESS command with Page Pool Restart set to disabled.

Programming Notes

The Page Pool Base Address must be set to a valid page if any batch buffer is enabled for the POSH pipe.

	15:0	**Reserved** Access: RO Format: MBZ

3DSTATE_PTBR_RENDER_LIST_BASE_ADDRESS

3DSTATE_PTBR_RENDER_LIST_BASE_ADDRESS

Source: PositionCS

Length Bias: 2

The 3DSTATE_PTBR_RENDER_LIST_BASE_ADDRESS command specifies a 4KB aligned base address for storing Render-Lists in PTBR mode. Render-List is an array consisting of starting page offset's corresponding to each of the tiles visibility data. Starting page offsets stored are offsets relative to Page Pool Base Address. The number of entries (array size) in a Render-List is equivalent to the number of tiles in a Tile Pass. Each Tile Pass has a corresponding Render-List populated by POSH pipe and each entry from the Render-List is read by Render Pipe when the corresponding tile is rendered.

Programming Notes

Both POSH pipe and Render pipe use the Render List Base Address programmed in POSH pipe, SW must ensure both POSH and Render pipe are flushed and synchronized prior to programing this command.
This command must be programmed only for POSH pipe and must not be programmed for render pipe. This command is context specific and must be programmed for each of the POSH enabled context. This command gets context save/restored as part of the POSH context.

The Render List Base Address must be set to a valid page if any batch buffer is enabled for the POSH pipe.

	7:0	**DWord Length** Format: =n Value / Name 02h: End Of Tile Pass Marker Not Set **[Default]** 0h: End Of Tile Pass Marker Set **Programming Notes** On setting the End Of;Tile Pass Marker, SW must not program the Dword2 and Dword3 of the

command and must accordingly program the Dword count in the header.

1 | 31 **End of Tile Pass**

Format:	Enable

Marker for indicating End of Tile Pass in a command sequence. This bit is always save/restored as 0 in HW CONTEXT.

Value	Name	Description
0	**[Default]**	Not an indicator of End of Tile Pass in a command sequence.
1		Indicates Start of Tile Pass in a command sequence.

Programming Notes

- A Tile Pass must begin with a Start of Tile Pass marker and end with End of Tile Pass marker.
- Start of Tile Pass marker and End of Tile Pass marker must not be set in the same command
- On setting the End of Tile Pass Marker, SW must not program the Dword2 and Dword3 of the command and must accordingly program the Dword count in the header.

30 **Start of Tile Pass**

Format:	Enable

Marker for indicating Start of Tile Pass in a command sequence.

Value	Name	Description
0	**[Default]**	Not an indicator of Start of Tile Pass in a command sequence.
1		Indicates Start of Tile Pass in a command sequence.

Programming Notes

- A Tile Pass must begin with a Start of Tile Pass marker and end with End of Tile Pass marker.
- Start of Tile Pass marker and End of Tile Pass marker must not be set in the same command

29 **Tile Pass Flag Status**

Format:	Enable

This bit is used by hardware to context save/restore the Tile Pass Flag status.

- When set indicates context got switched out is in middle of a Tile Pass,
- when reset indicates context got switched out outside the Tile Pass.

Value	Name	Description
0	**[Default]**	Context got switched out outside the Tile Pass.
1		Context got switched out in middle of a Tile Pass.

3DSTATE_PTBR_TILE_PASS_INFO

		Programming Notes SW must never set this bit.
	28:10	**Reserved** Access: RO Format: MBZ
	9:0	**Tile Count** Format: U10-1 **Description** Tile Count indicates the number of tiles the render region is divided in to, a maximum of 128 tiles is supported by POSH pipe and a maximum of 1024 tiles by Render pipe. A tile count of zero is a special indication stating the whole render region is considered as one single tile of the dimensions of the drawing rectangle. A tile count of 1 indicates the whole render region is divided in to two tiles and tile count of 127 indicates the render region is divided in to 128 tiles. For a Tile Count greater then '0', Tile Rect Array Pointer provides the details for each of the tiles dimensions. **Value / Name / Description** 0h — Default **[Default]** — The whole render region is considered as one single tile of the dimensions of the drawing rectangle. 7Fh — POSH Max Value — The render region is divided in to 128 tiles. 3FFh — Render Max Value — The render region is divided in to 1024 tiles. **Programming Notes** "Tile Count" value programmed must be same in the 3DSTATE_PTBR_TILE_PASS_INFO command programmed for "Start of Tile Pass" and for "End of Tile Pass".
2	31:6	**Tile Rect Array Pointer** Format: DynamicStateOffset[31:6]TILE_RECT Specifies the 64-byte aligned offset pointing to the element zero of an array, each element is a TILE_RECT state. This offset is relative to the Dynamic State Base Address. Each TILE_RECT state is two dwords in size comprising {Y Max, X Max, Y Min, X Min} of the tile. Number of TILE_RECT states in the array is equivalent to the tile count. Example: For a Tile count of 63, 64 TILE_RECT states are programmed in consecutive memory locations constituting the array, i.e 64 consecutive qwords (qword-64bits) of data in the memory, with starting qword corresponding to the TILE_RECT state of tile0 and the last qword corresponding to tile-63.
	5:0	**Reserved** Access: RO Format: MBZ

3DSTATE_PTBR_TILE_PASS_INFO

3	31:6	**Render List Pointer** Format: RenderListOffset[31:6] Specifies the 64byte offset pointing to Render-List of the current Tile Pass. This offset is relative to PTBR_RENDER_LIST_BASE_ADDRESS. Render-List is an array consisting of starting page offset's corresponding to each of the tiles visibility data. Starting page offsets stored are 16bit offsets relative to PTBR_PAGE_POOL_BASE_ADDRESS. The number of entries (array size) in a Render-List is equivalent to the tile count of the current Tile Pass.
	5:2	**Reserved** Access: RO Format: MBZ
	1	**Reserved** Access: RO Format: MBZ

	0	**Initialize Render List**
		Format: Enable
		On parsing this command with Initialize Render List set, POSH pipe allocates a page for each of the tile from the Free-List to which respective visibility data will be outputted. The page offsets corresponding to these pages are written to the Render-List. POSH pipe doesn't parse the next command in sequence until the Render-List is populated. Each entry from the Render-List is read by Render Pipe when the corresponding tile is rendered. Example: For a Tile count of 63, POSH pipe will write to 64 consecutive Words (2bytes) to the Render-List, where in word-0 belongs to Tile-0, word1 belongs to Tile-1 word-63 belongs to Tile-63.
		This bit is ignored by RenderCS on executing 3DSTATE_PTBR_TILE_PASS_INFO command.
		Programming Notes
		SW must ensure Render-List is populated by POSH pipe before it gets read by the Render pipe. This can be achieved by using semaphores in render pipe command sequence to wait for POSH pipe to complete Render-List update.
		• SW must always set this bit to '1'.
		• SW must Initialize Render List only once in a Tile Pass.
		• SW must ensure to program the below listed commands prior to programming 3DSTATE_PTBR_TILE_PASS_INFO with "Initialize Render List bit set.
		  • 3DSTATE_PTBR_PAGE_POOL_BASE_ADDRESS
		  • 3DSTATE_PTBR_FREE_LIST
		  • 3DSTATE_PTBR_RENDER_LIST
		This bit is always save/restored as 0 in HW CONTEXT.

3DSTATE_PTBR_TILE_SELECT

3DSTATE_PTBR_TILE_SELECT

Source: RenderCS

Length Bias: 2

The 3DSTATE_PTBR_TILE_SELECT command is programmed in render engine to define the required parameters for a tile to be rendered in POSH Tile Base Rendering mode (PTBR).
This command must be programmed only for render pipe and must not be programmed for POSH pipe. This command is context specific and must be programmed for each of the POSH enabled context. This command gets context save/restored by render engine as part of the render context.

Programming Notes

SW must ensure Render-List is populated by POSH pipe before it gets read by the Render pipe.
This can be achieved by using semaphores in render pipe command sequence to wait for POSH pipe to complete Render-List update prior to programming of 3DSTATE_PTBR_TILE_SELECT command.

3DSTATE_PUSH_CONSTANT_ALLOC_DS

3DSTATE_PUSH_CONSTANT_ALLOC_DS

Source: RenderCS

Length Bias: 2

This command sets up the URB configuration for DS Push Constant Buffer.

Programming Notes

Programming Restriction:

- The sum of the Constant Buffer Offset and the Constant Buffer Size may not exceed the maximum value of the Constant Buffer Size.
- The sum of the constant length of the push constants must be equal or smaller than the size of the allocated space in the URB including the buffering for half cachelines. See **Push Constant URB Allocation section for more details**.
- The Domain Shader Push Constants state must be programmed prior to any state is committed into the pipeline or any preemptible command(i.e. prior to PIPE_CONTROL, 3DPRIMITIVE, 3DMESH or COMPUTE_WALKER)after programming the 3DSTATE_PUSH_CONSTANT_ALLOC_DS.

When gather at set shader is disabled, Push Constant command is committed when 3DPRIMITIVE command is parsed.
When gather at set shader is enabled, commit point on the Push Constant command is a 3DSTATE_BINDING_TABLE_POINTER command.

The 3DSTATE_BINDING_TABLE_POINTER must be reprogrammed after 3DSTATE_PUSH_CONST_ALLOC command and the reprogramming of the push constants prior to the next 3DPRIMITIVE if gather at set shader is enabled to ensure the new programming is committed.

DWord	Bit	Description

	5:0	**Constant Buffer Size** Format: U6 Specifies the size of the PS constant buffer. This value will determine the amount of data the command stream can pre-fetch before the buffer is full. Value of zero is only valid when constants are not enabled for PS. **Value** [0,32] — **Name** (0KB - 32KB) Increments of 2KB

3DSTATE_PUSH_CONSTANT_ALLOC_VS

3DSTATE_PUSH_CONSTANT_ALLOC_VS

Source: RenderCS

Length Bias: 2

This command sets up the URB configuration for VS Push Constant Buffer.

Programming Notes

Programming Restriction:

- The sum of the Constant Buffer Offset and the Constant Buffer Size may not exceed the maximum value of the Constant Buffer Size.
- The sum of the constant length of the push constants must be equal or smaller than the size of the allocated space in the URB including the buffering for half cachelines. See **Push Constant URB Allocation section for more details**.
- The VertexShader Push Constants state must be programmed prior to any state is committed into the pipeline or any preemptible command(i.e. prior to PIPE_CONTROL, 3DPRIMITIVE, 3DMESH or COMPUTE_WALKER)after programming the 3DSTATE_PUSH_CONSTANT_ALLOC_VS.

When executed in the POCS command stream, this command programs state for the VSR stage of the POCS pipeline. The offset & size of the VSR allocation is relative to the 32KB of URB reserved for POCS pipe Push Constant Buffers, vs. the 32KB used by the RCS pipe.

When gather at set shader is disabled, programmed constants are committed when 3DPRIMITIVE command is parsed.
When gather at set shader is enabled, commit point of the constants programmed area 3DSTATE_BINDING_TABLE_POINTER command.

The 3DSTATE_BINDING_TABLE_POINTER must be reprogrammed after 3DSTATE_PUSH_CONST_ALLOC command and the reprogramming of the push constants prior to the next 3DPRIMITIVE if gather at set shader is enabled to ensure the new programming is committed.

DWord	Bit	Description

1	31:0	**Sample Mask State Body** Format: 3DSTATE_SAMPLE_MASK_BODY

3DSTATE_SAMPLE_PATTERN

3DSTATE_SAMPLE_PATTERN

Source: RenderCS

Length Bias: 2

The 3DSTATE_SAMPLE_PATTERN command is used to specify the sample offsets for all multisample sample modes. The set of offset used will be selected based on the multisample mode. This is non-pipelined state.

Programming Notes

When programming the sample offsets (for NUMSAMPLES_4 or _8 and MSRASTMODE_xxx_PATTERN), the order of the samples 0 to 3 (or 7 for 8X, or 15 for 16X) must have monotonically increasing distance from the pixel center. This is required to get the correct centroid computation in the device.

Restriction : When executed in the POCS command stream, this command programs the multisample pattern state for the CLR and SFR stage of the POCS pipeline

DWord	Bit	Description

3DSTATE_SO_BUFFER

3DSTATE_SO_BUFFER

Source: RenderCS

Length Bias: 2

Programming Notes

Foreach SO Buffer, the 3DSTATE_SO_BUFFER must only be sent once prior to each 3DPRIMITIVE command.

Workaround

Workaround : This command must be followed by a PIPE_CONTROL with CS Stall bit set.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode
	28:27	**Command SubType** Default Value: 3h GFXPIPE_3D Format: OpCode
	26:24	**3D Command Opcode** Default Value: 1h 3DSTATE_NONPIPELINED Format: OpCode
	23:16	**3D Command Sub Opcode** Default Value: 18h 3DSTATE_SO_BUFFER Format: OpCode
	15:8	**Reserved** Access: RO Format: MBZ
	7:0	**DWord Length** Default Value: 6h Excludes DWord (0,1) Format: =n Total Length - 2
1	31	**SO Buffer Enable** Format: Enable If set, stream output to SO Buffer is enabled, , if 3DSTATE_STREAMOUT::SO Function ENABLE is also enabled..If clear, the SO Buffer is considered "not bound" and effectively treated as a zero-length buffer for the purposes of SO output and overflow detection. If an enabled stream's Stream to Buffer Selects includes this buffer it is by definition an overflow condition. That stream will cause no writes to occur, and only SO_PRIM_STORAGE_NEEDED[<stream>] will increment.

3DSTATE_SO_BUFFER

	30:29	**SO Buffer Index** Format: U2 Specifies which of the four SO Buffers is being defined.
	28:22	**SO Buffer Object Control State** Format: MEMORY_OBJECT_CONTROL_STATE Specifies the memory object control state for the SO buffer.
	21	**Stream Offset Write Enable** Format: Enable When set, this field allows the hardware to write SO_WRITE_OFFSET[Buffer#] as specified in the Stream Offset field. **Programming Notes** The field is operates irrespective of whether SO Buffer Enable is set or clear.
	20	**Stream Output Buffer Offset Address Enable** Format: Enable When set, this field allows the hardware to read/write the stream output buffer offset as specified in the "Stream Output Buffer Offset Address" field. **Programming Notes** The field is operates irrespective of whether SO Buffer Enable is set or clear.
	19:0	**Reserved** Access: RO Format: MBZ
2..3	63:2	**Surface Base Address** Format: VIRTUAL_ADDR[63:2] This field specifies the starting address of the buffer in Graphics Memory.
	1:0	**Reserved** Access: RO Format: MBZ
4	31:30	**Reserved** Access: RO Format: MBZ
	29:0	**Surface Size** Format: U30-1 This field specifies the size of buffer in number DWords minus 1 of the buffer in Graphics Memory.

<table>
<tr><th colspan="3">3DSTATE_SO_BUFFER</th></tr>
<tr><td>5..6</td><td>63:2</td><td>Stream Output Buffer Offset Address
<table><tr><td>Format:</td><td>VIRTUAL_ADDR[63:2]</td></tr></table>This field specifies the starting address of the buffer in Graphics Memory where the Stream Output Buffer Offset is stored when all the data has been written. It is also used to fetch the stream Output buffer Offset when needed.</td></tr>
<tr><td></td><td>1:0</td><td>Reserved
<table><tr><td>Access:</td><td>RO</td></tr><tr><td>Format:</td><td>MBZ</td></tr></table></td></tr>
<tr><td>7</td><td>31:0</td><td>Stream Offset
This field specifies the Offset in stream output buffer to start at, or whether to append to the end of an existing buffer. The Offset must be DWORD aligned. If Stream Offset is equal to 0xFFFFFFFF then load the value at the Stream Output Buffer Offset address into SO_WRITE_OFFSET[Buffer#]. Otherwise, SO_WRITE_OFFSET[Buffer#] = Stream Offset.</td></tr>
</table>

3DSTATE_SO_DECL_LIST

3DSTATE_SO_DECL_LIST

Source: RenderCS

Length Bias: 2

Workaround
Workaround : This command must be followed by a PIPE_CONTROL with CS Stall bit set.,

1	31:16	**Reserved** Access: RO Format: MBZ
	15:12	**Stream to Buffer Selects [3]** Format: U4 Identifies to which SO Buffers stream 3 outputs. See Stream To Buffer Selects [0] field description. Value | Name 1xxxb | SO Buffer 3 x1xxb | SO Buffer 2

	xx1xb	SO Buffer 1
	xxx1b	SO Buffer 0

11:8 Stream to Buffer Selects [2]

Format:	U4

Identifies to which SO Buffers stream 2 outputs. See Stream To Buffer Selects [0] field description.

Value	Name
1xxxb	SO Buffer 3
x1xxb	SO Buffer 2
xx1xb	SO Buffer 1
xxx1b	SO Buffer 0

7:4 Stream to Buffer Selects [1]

Format:	U4

Identifies to which SO Buffers stream 1 outputs. See Stream To Buffer Selects [0] field description.

Value	Name
1xxxb	SO Buffer 3
x1xxb	SO Buffer 2
xx1xb	SO Buffer 1
xxx1b	SO Buffer 0

3:0 Stream to Buffer Selects [0]

Format:	U4

Identifies to which SO Buffers stream 0 outputs (irrespective of whether those buffers are enabled via 3DSTATE_STREAMOUT). Software is required to scan the SO_DECL list in order to provide this summary information.Note: For "inactive" streams, software must program this field to all zero (no buffers written to) and the corresponding Num Entries field to zero (no valid SO_DECLs).

Value	Name
1xxxb	SO Buffer 3
x1xxb	SO Buffer 2
xx1xb	SO Buffer 1
xxx1b	SO Buffer 0

2 31:24 Num Entries [3]

Format:	U8

Specifies the number of valid SO_DECL entries for Stream 3. (See notes in Num Entries [0] field description).

Value	Name
[0,128]	entries

3DSTATE_SO_DECL_LIST

	23:16	**Num Entries [2]** Format: U8 Specifies the number of valid SO_DECL entries for Stream 2. (See notes in Num Entries [0] field description). **Value** / **Name** [0,128] entries
	15:8	**Num Entries [1]** Format: U8 Specifies the number of valid SO_DECL entries for Stream 1. (See notes in Num Entries [0] field description). **Value** / **Name** [0,128] entries
	7:0	**Num Entries [0]** Format: U8 Specifies the number of valid SO_DECL entries for Stream 0.Note that the SO_DECLs are programmed in groups of four (one SO_DECL for each of the four streams). Therefore the number of 2-DWord groups of SO_DECLs supplied in this command is derived from the stream(s) with the most valid SO_DECLs. The NumEntries value specific to each stream will indicate how many SO_DECLS are valid for that particular stream. Any trailing invalid SO_DECLs supplied for streams with fewer valid SO_DECLs will be ignored. It is legal to specify Num Entries = 0 for all four streams simultaneously. In this case there will be no SO_DECLs included in the command (only DW 0-2). Note that all Stream to Buffer Selects bits must be zero in this case (as no streams produce output). **Value** / **Name** [0,128] entries
3..n	63:0	**Entry** Format: SO_DECL_ENTRY

3DSTATE_STENCIL_BUFFER

3DSTATE_STENCIL_BUFFER

Source: RenderCS

Length Bias: 2

The stencil buffer surface state is delivered as a pipelined state packet. However, the state change pipelining isn't completely transparent (see restriction below).

WM HW will internally manage the draining pipe and flushing of the caches when this command is issued. The PIPE_CONTROL restrictions are removed.

Programming Notes

If the Stencil surface is not present, SW must set the Surface Type fieldto SURFTYPE_NULL.

DWord	Bit	Description

3DSTATE_URB_ALLOC_DS

3DSTATE_URB_ALLOC_DS

Source: RenderCS

Length Bias: 2

When executed from the RCS command stream, this command provides the state variables associated with the URB region used by the DS pipeline stage.

Separate state variables are provided to define the URB region for Slice0 as well as additional URB space for additional slices (if any are enabled). Hardware will use those values to automatically compute the URB allocation within the total URB space based on the number of enabled slices. Software shall ensure that the values programmed do not exceed the URB capacity of a slice. Refer to the L3 allocation and programming guide for valid URB configurations.

Programming Notes

SW shall ensure that the ordering of URB allocations is consistent between the Slice0 and SliceN state settings across all FF stage URB allocations.

SW shall issue allocation state for all FF stages, i.e., 3DSTATE_URB_ALLOC_VS, 3DSTATE_URB_ALLOC_HS, 3DSTATE_URB_ALLOC_DS, and 3DSTATE_URB_ALLOC_GS commands.

If Domain Shader Thread Dispatch is Enabled then the minimum number of handles that must be allocated is 50 URB entries.

SW shall ensure that the URB region specified by this command does not overlap with the push constant allocation in the URB, as defined by the 3DSTATE_PUSH_CONSTANT_ALLOC_VS, 3DSTATE_PUSH_CONSTANT_ALLOC_DS, 3DSTATE_PUSH_CONSTANT_ALLOC_HS, and 3DSTATE_PUSH_CONSTANT_ALLOC_GS commands.

3DSTATE_URB_ALLOC_VS

3DSTATE_URB_ALLOC_VS

Source: RenderCS, PositionCS

Length Bias: 2

When executed from the RCS command stream, this command provides the state variables associated with the URB region used by the VF and VS pipeline stages.

When executed from the POCS command stream, this command provides the state variables associated with the URB region used by the VFR and VSR pipeline stages. The POCS command stream will only execute 3DSTATE_URB_ALLOC_VS command with respect to URB programming for the POCS 3D pipeline. 3DSTATE_URB_ALLOC_HS, 3DSTATE_URB_ALLOC_DS and 3DSTATE_URB_ALLOC_GS commands are ignored by the POCS command stream.

Separate state variables are provided to define the URB region for Slice0 as well as additional URB space for additional slices (if any are enabled). Hardware will use those values to automatically compute the URB allocation within the total URB space based on the number of enabled slices. Software shall ensure that the values programmed do not exceed the URB capacity of a slice. Refer to the L3 allocation and programming guide for valid URB configurations.

Programming Notes

SW shall ensure that the ordering of URB allocations is consistent between the Slice0 and SliceN state settings across all FF stage URB allocations.

The VSR URB region shall never overlap any other URB region. As POCS and RCS command streams are not implicitly synchronized, if POCS is used SW shall reserve a region of the URB for use by VSR. Both pipelines must be flushed and synchronized before expanding the VSR URB region such that the new VSR URB region overlaps URB space previously used by the render pipeline, or the URB space to be used by the render pipeline overlaps the previous VSR URB region.

When specifying URB allocation state for the RCS 3D pipe, SW shall issue allocation state for all FF stages, i.e., 3DSTATE_URB_ALLOC_VS, 3DSTATE_URB_ALLOC_HS, 3DSTATE_URB_ALLOC_DS, and 3DSTATE_URB_ALLOC_GS commands.

SW shall ensure that the URB region specified by this command does not overlap with the push constant allocation in the URB, as defined by the 3DSTATE_PUSH_CONSTANT_ALLOC_VS, 3DSTATE_PUSH_CONSTANT_ALLOC_DS, 3DSTATE_PUSH_CONSTANT_ALLOC_HS, and 3DSTATE_PUSH_CONSTANT_ALLOC_GS commands.

3DSTATE_URB_DS

3DSTATE_URB_DS

Source: RenderCS

Length Bias: 2

This command may not overlap with the push constants in the URB defined by the 3DSTATE_PUSH_CONSTANT_ALLOC_VS, 3DSTATE_PUSH_CONSTANT_ALLOC_DS, 3DSTATE_PUSH_CONSTANT_ALLOC_HS, and 3DSTATE_PUSH_CONSTANT_ALLOC_GS commands.

The URB Starting Address and Number of URB Entries fields shall be programmed as if there is only one slice enabled. When more than one slice is enabled, hardware will (a) recompute the actual URB Starting Address based on the number of enabled slices and (b) multiply the Number of URB Entries by the number of enabled slices. Software shall ensure that the values programmed do not exceed the URB capacity of a single slice. Refer to the L3 allocation and programming guide for valid URB configurations.

Programming Notes

When programming DS URB state for the RCS 3D pipe, 3DSTATE_URB_VS, 3DSTATE_URB_HS, and 3DSTATE_URB_GS must also be programmed in order for the programming of this state to be valid.

Please see **3DSTATE_URB_ALLOC_DS** for any new programming notes related to URB programming.

3DSTATE_URB_VS

3DSTATE_URB_VS

Source: RenderCS, PositionCS

Length Bias: 2

Description
VS URB Entry Allocation Size equal to 4(5 512-bit URB rows) may cause performance to decrease due to banking in the URB. Element sizes of 16 to 20 should be programmed with six 512-bit URB rows.
This command may not overlap with the push constants in the URB defined by the 3DSTATE_PUSH_CONSTANT_ALLOC_VS, 3DSTATE_PUSH_CONSTANT_ALLOC_DS, 3DSTATE_PUSH_CONSTANT_ALLOC_HS, and 3DSTATE_PUSH_CONSTANT_ALLOC_GS commands.
The offset and size should be programmed as if there is only one slice enabled. Hardware will grow the size based on the slice configuration. Software shall ensure that the values programmed do not exceed the URB capacity of one slice. Refer to the L3 allocation and programming guide for valid URB configurations.
When executed from the POCS command stream, state for the VSR stage is set. The VSR URB region shall never overlap any other URB region. As POCS and RCS command streams are not implicitly synchronized, if POCS is used SW shall reserve a region of the URB for use by VSR. Both pipelines must be flushed and synchronized before expanding the VSR URB region such that the new VSR URB region overlaps URB space previously used by the render pipeline, or the URB space to be used by the render pipeline overlaps the previous VSR URB region. The POCS command stream will only execute 3DSTATE_URB_VS command with respect to URB programming for the POCS 3D pipeline. 3DSTATE_URB_HS, 3DSTATE_URB_DS and 3DSTATE_URB_GS commands are ignored by the POCS command stream.

Programming Notes
When programming VS URB state for the RCS 3D pipe, 3DSTATE_URB_HS, 3DSTATE_URB_DS, and 3DSTATE_URB_GS must also be programmed in order for the programming of this state to be valid.
Please see **3DSTATE_URB_ALLOC_VS** for any new programming notes related to URB programming.

3DSTATE_VERTEX_BUFFERS

3DSTATE_VERTEX_BUFFERS

Source: RenderCS

Length Bias: 2

This command is used to specify VB state used by the VF function.

Can specify from 1 to 33 VBs.

The VertexBufferID field within a VERTEX_BUFFER_STATE structure indicates the specific VB. If a VB definition is not included in this command, its associated state is left unchanged and is available for use if previously defined.

Programming Notes

It is possible to have individual vertex elements sourced completely from generated ID values and therefore not require any vertex buffer accesses for that vertex element. In this case, VF function will simply ignore the VB state associated with that vertex element. If all enabled vertex elements have this characteristic, no VBs are required to process 3DPRIMITIVE commands. For example, this might arise when the user wants to perform all data lookups in the first shader, so only generated index values need to be passed down to it. In this extreme case, SW would not need to program any VB state, and therefore not need to issue any 3DSTATE_VERTEX_BUFFERS commands.

For any 3DSTATE_VERTEX_BUFFERS command, at least one VERTEX_BUFFER_STATE structure must be included.

VERTEX_BUFFER_STATE structures are 4 DWords for both VERTEXDATA buffers and INSTANCEDATA buffers.

Inclusion of partial VERTEX_BUFFER_STATE structures is UNDEFINED.

The order in which VBs are defined within this command can be arbitrary, though a vertex buffer must be defined only once in any given command (otherwise operation is UNDEFINED).

When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline.

DWord	Bit	Description

3DSTATE_VERTEX_ELEMENTS

3DSTATE_VERTEX_ELEMENTS

Source: RenderCS

Length Bias: 2

This is a variable-length command used to specify the active vertex elements. Each VERTEX_ELEMENT_STATE structure contains a Valid bit which determines which elements are used. Any elements not programmed by this command are disabled.

Up to 34 elements.

Programming Notes

- At least one VERTEX_ELEMENT_STATE structure must be included.
- Inclusion of partial VERTEX_ELEMENT_STATE structures is UNDEFINED.
- SW must ensure that at least one vertex element is defined prior to issuing a 3DPRIMTIVE command, or operation is UNDEFINED.
- There are no 'holes' allowed in the destination vertex: NOSTORE components must be overwritten by subsequent components unless they are the trailing DWords of the vertex. Software must explicitly chose some value (probably 0) to be written into DWords that would otherwise be 'holes'.
- Within a VERTEX_ELEMENT_STATE structure, if a Component Control field is set to something other than VFCOMP_STORE_SRC, no higher-numbered Component Control fields may be set to VFCOMP_STORE_SRC. In other words, only trailing components can be set to something other than VFCOMP_STORE_SRC.
- See additional restrictions listed in the command fields and VERTEX_ELEMENT_STATE description.
- Element[0] must be valid.
- All elements must be valid from Element[0] to the last valid element. (E.g.. if Element[2] is valid then Element[1] and Element[0] must also be valid).
- The pitch between elements packed in the URB will always be 128 bits.
- When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline.

3DSTATE_VF_COMPONENT_PACKING

3DSTATE_VF_COMPONENT_PACKING

Source: RenderCS

Length Bias: 2

This command is used to specify, separately for Vertex Elements [0-31], which post-conversion, 32-bit components are "enabled" to be stored in the URB , and which are "disabled" (not stored). 128 per-component enable bits are provided. Disabling all four components for a given Vertex Element will result in no data stored for that element. Note that any insertion of SGVs (3DSTATE_VF_SGVS) is performed before the packing operation. The **Component Packing Enable** bit (3DSTATE_VF) controls the overall packing process. If that bit is set, the packing process is enabled and the bit mask provided in this command is used to control which components are stored. If that bit is clear, the packing process is disabled - all four components of "valid" Vertex Elements will be stored.

Programming Notes

Programming Restrictions:

- The Vertex Elements referenced in this command correspond to the first 32 VERTEX_ELEMENT structures passed in 3DSTATE_VERTEX_ELEMENTS. A Vertex Element must be marked as "Valid" via 3DSTATE_VERTEX_ELEMENTS or be an SGV or an element between the last valid element and the last SGV in order for the corresponding Component Enable bits of this command to be utilized.
- No enable bits are provided for Vertex Elements [32-33], and therefore no packing is performed on these elements (if Valid, all 4 components are stored).
- If a Vertex Element has Edge Flag Enable set no packing is performed for that element and the corresponding packing state is ignored.
- Component packing is probably only useful for SIMD8 VS thread execution.

At least one component of one "valid" Vertex Element must be enabled.

When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline.

Software shall enable all components (XYZW) for any and all VERTEX_ELEMENTs associated with a 256-bit SURFACE_FORMAT. It is INVALID to disable any components in these cases.

		Format:	3DSTATE_VF_BODY

3DSTATE_VF_SGVS_2

3DSTATE_VF_SGVS_2

Source: RenderCS

Length Bias: 2

This command is used to control the insertion of the Extended Parameter (XP0-2) System-Generated Values (SGVs) into an input Vertex URB Entry (VUE) (available as input to a VS thread). The insertions are individually controlled. The insertion locations are specified as 128-bit element locations (starting at the beginning of the VUE) and 32-bit component within those specified elements. The SGV values can be inserted either (a) within a valid vertex element (in which case the value overwrites the value specified via 3DSTATE_VERTEX_ELEMENTS) or (b) beyond the last valid vertex element written to the URB. This permits some orthogonality between the programming of vertex elements (which typically is known at draw time) and programming of SGV insertion (which is associated with the shader). There are some restrictions however (see below). If an SGV is inserted beyond the last valid vertex element, zeroes are first inserted in the VUE after the last valid vertex element up to and including the vertex element receiving an SGV. If both of the SGVs are enabled for insertion, the zeroes will extend to the last vertex element receiving and SGV. Then the SGV(s) are inserted.
The sources for these SGV values are derived from 3DPRIMITIVE command parameters. Controls in the 3DPRIMITIVE command determine whether (a) the parameters are directly defined via in-line command DWords, (b) the parameters are indirectly specified by command stream registers, or (c) the parameters are not included in the 3DPRIMITIVE command and therefore default to 0. Refer to the 3DPRIMITIVE command description for details on these different cases.
The states included in this command are used to (a) enable/disable specific XP* SGV insertions and (b) for XP0 and XP1, specify which 3DPRIMITIVE parameters are used to source the inserted SGV value.

The insertion of SGV values occurs before any component packing (3DSTATE_VF_COMPONENT_PACKING). Therefore, the Element Offsets and Component Numbers specified in this command refer to the pre-packed data, following 3DSTATE_VERTEX_ELEMENT processing.

Programming Notes

Programming Restrictions:

- It is INVALID to specify that more than one SGV is to be stored in the same element/component location within the VUE.
- The states programmed by this command overwrite the state programmed by any previous commands. I.e., a specific SGV (if enabled) can only be inserted in one component of a vertex.
- It is INVALID to insert an SGV value past the end of the VUE entry (as determined by VS URB Entry Allocation Size) or past the 33rd vertex element. Therefore, the programming of VS URB Entry Allocation Size needs to comprehend any SGV insertion requirements.
- It is INVALID to use this command to overwrite any portion of a 64-bit vertex element component.

When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline.

3DSTATE_VF_SGVS

3DSTATE_VF_SGVS

Source: RenderCS

Length Bias: 2

This command is used to control the insertion of the VertexID and InstanceID System-Generated Values (SGVs) into an input Vertex URB Entry (VUE) (available as input to a VS thread). VertexID and InstanceID insertion can be individually controlled. The insertion locations are specified as 128-bit element locations (starting at the beginning of the VUE) and the 32-bit component within those specified elements. The SGV values can be inserted either (a) within a valid vertex element (in which case the value overwrites the value specified via 3DSTATE_VERTEX_ELEMENTS) or (b) beyond the last valid vertex element written to the URB. This permits some orthogonality between the programming of vertex elements (which typically is known at draw time) and programming of SGV insertion (which is associated with the shader). There are some restrictions however (see below). If an SGV is inserted beyond the last valid vertex element, zeroes are first inserted in the VUE after the last valid vertex element up to and including the vertex element receiving an SGV. If both of the SGVs are enabled for insertion, the zeroes will extend to the last (largest index) vertex element receiving an SGV. Then the SGV(s) are inserted.

The insertion of SGV values occurs before any component packing (3DSTATE_VF_COMPONENT_PACKING). Therefore, the Element Offsets and Component Numbers specified in this command refer to the pre-packed data, following 3DSTATE_VERTEX_ELEMENT processing.

Programming Notes

Programming Restrictions:

- It is INVALID to store both the VertexID and InstanceID in the same element/component location within the VUE.
- The states programmed by this command overwrite the state programmed by any previous commands. I.e., VertexID and InstanceID (if enabled) can only be inserted in one component of a vertex.
- It is INVALID to insert an SGV value past the end of the VUE entry (as determined by VS URB Entry Allocation Size) or past the 33rd vertex element. Therefore, the programming of VS URB Entry Allocation Size needs to comprehend any SGV insertion requirements.
- It is INVALID to use this command to overwrite any portion of a 64-bit vertex element component.
- It is INVALID to use this command to overwrite a EdgeFlag vertex element component or any vertex element beyond it.

When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode
	28:27	**Command SubType** Default Value: 3h GFXPIPE_3D

3DSTATE_VF_SGVS

		Format: OpCode

1	31:0	**VF SGVS State Body** Format: 3DSTATE_VF_SGVS_BODY

3DSTATE_VF_STATISTICS

3DSTATE_VF_STATISTICS

Source: RenderCS

Length Bias: 1

The VF stage tracks two pipeline statistics, the number of vertices fetched and the number of objects generated. VF will increment the appropriate counter for each when statistics gathering is enabled by issuing the 3DSTATE_VF_STATISTICS command with the [Statistics Enable] bit set.

Programming Notes

When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: Opcode
	28:27	**Command SubType** Default Value: 1h GFXPIPE_SINGLE_DW Format: Opcode
	26:24	**3D Command Opcode** Default Value: 0h 3DSTATE_PIPELINED Format: Opcode GFXPIPE[28:27 = 1h, 26:24 = 0h, 23:16 = 0Bh] (Pipelined, Single DWord)
	23:16	**3D Command Sub Opcode** Default Value: 0Bh 3DSTATE_VF_STATISTICS Format: Opcode GFXPIPE[28:27 = 1h, 26:24 = 0h, 23:16 = 0Bh] (Pipelined, Single DWord)
	15:1	**Reserved** Access: RO Format: MBZ
	0	**Statistics Enable** Format: Enable If ENABLED, VF will increment the pipeline statistics counters IA_VERTICES_COUNT and IA_PRIMITIVES_COUNT for each vertex fetched and each object output, respectively, for 3DPRIMITIVE commands issued subsequently.If DISABLED, these counters will not be incremented for subsequent 3DPRIMITIVE commands. **Programming Notes** When a 3DPRIMITIVE command with POSH Enable set is executed from the RCS command stream, VF statistics gathering is inhibited for that command.

3DSTATE_VF_TOPOLOGY

3DSTATE_VF_TOPOLOGY

Source: RenderCS

Length Bias: 2

This command specifies the VF stage's Topology state which can be used to override the Primitive Topology Type in subsequent 3DPRIMITIVE commands.

Programming Notes

When executed in the POCS command stream, this command programs state for the VFR stage of the POCS pipeline, and only the following topologies are valid: 3DPRIM_TRILIST, 3DPRIM_TRISTRIP, 3DPRIM_TRISTRIP_REV.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h GFXPIPE Format: OpCode

3DSTATE_VS

3DSTATE_VS

Source: RenderCS, PositionCS

Length Bias: 2

This command specifies most of the state used by the Vertex Shader (VS) stage.

Programming Notes

When executed in the POCS command stream, this command programs state for the VSR stage of the POCS pipeline. When executed in the RCS command stream, this command programs state for the VS stage of the RCS pipeline.

1..3	95:0	**WM Depth Stencil State Body** Format: 3DSTATE_WM_DEPTH_STENCIL_BODY

3DSTATE_WM_HZ_OP

3DSTATE_WM_HZ_OP

Source: RenderCS

Length Bias: 2

This command provides for clearing Z and/or stencil or resolving either HZ buffer or Z buffer.

Programming Notes

As this command generates an implicit rectangle, SW must make sure any MMIO register writes following WM_HZ_OP must be preceded by **PIPE_CONTROL** with **Command Streamer Stall Enable** bit set.

3DSTATE_DRAWING_RECTANGLE must be programmed such that it does not clip the HZ_OP command's rectangle. See programming notes for X/Y Min and X/Y Max below.
3DSTATE_DRAWING_RECTANGLE command must come before 3DSTATE_WM_HZ_OP in the command buffer
Caution: There is a difference in how X/Y coordinates are interpreted by 3DSTATE_DRAWING_RECTANGLE vs. 3DSTATE_WM_HZ_OP.
HZ_OP rectangle parameters are exclusive on max side, for example to have 8x4 rectangle we would program X Min = 0, Y Min = 0, X Max = 8, Y Max = 4.
Draw Rectangle parameters are inclusive on max side, meaning, for 8x4 rectangle the values would be X Min = 0, Y Min = 0, X Max = 7, Y Max = 3.

3DSTATE_MULTISAMPLE packet must be used prior to this packet to change the Number of Multisamples. This packet must not be used to change Number of Multisamples in a rendering sequence.
3DSTATE_RASTER if used must be programmed prior to using this packet.

SW should flush the Depth Cache AFTER the following WM_HZ_OP commands
1. Depth Clear
2. HIZ Resolve

Addition

add - Addition

Source:	EuIsa
Length Bias:	4
Predication:	true
Conditional Modifier:	true
Saturation:	true
Source Modifier:	true

The add instruction performs component-wise addition of src0 and src1 and stores the results in dst. Addition of two floating-point numbers follows rules in add (IEEE mode) or add (ALT mode).

Format:

```
[(pred)] add[.cmod] (exec_size) dst src0 src1
```

Programming Notes

Use a source modifier with add to implement subtraction.

Syntax

[(pred)] add[.cmod] (exec_size) reg reg reg
[(pred)] add[.cmod] (exec_size) reg reg imm32

Pseudocode

```
Evaluate(WrEn);

 for ( n = 0; n < exec_size; n++ ) {
   if ( WrEn.chan[n] ) {
     dst.chan[n] = src0.chan[n] + src1.chan[n];
   }
 }
```

add - Addition

	39:36	**Dst.DataType** Format: **RegDataType**
	35	**Dst.AddrMode** Format: **AddrMode**
	34	**Saturate** Format: **Saturate**
	33	**AccWrCtrl** Format: **AccWrCtrl**
	32	**AtomicCtrl** Format: **AtomicCtrl**
	31	**MaskCtrl** Mask Control (formerly Write Enable Control). This field determines if the per channel write enables are used to generate the final write enable. This field should be normally "0". **Value** / **Name** / **Description** 0 / Normal **[Default]** / Normal. Per channel write enable used for final write enable generation. 1 / NoMask / NoMask.Skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.
	30	**Reserved**
	29	**CmptCtrl** Format: MBZ Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information. **Value** / **Name** / **Description** 0 / NoCompaction **[Default]** / No compaction. 128-bit native instruction supporting all instruction options. 1 / Compacted / Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.
	28	**PredInv** This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields **Value** / **Name** / **Description**

		0 | Positive **[Default]** | Positive polarity of predication. Use the predication mask produced by PredCtrl. 1 | Negative | Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.
	27:24	**PredCtrl** Format: **PredCtrl** This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register.
	23	**FlagRegNum[0]** This field specifies bit[0] of the register number for a flag register operand.
	22	**FlagSubRegNum** This field specifies the sub-register number for a flag register operand. There are two sub-registers in the flag register. Each sub-register contains 16 flag bits. The selected flag sub-register is the source for predication if predication is enabled for the instruction. It is the destination to store conditional flag bits if conditional modifier is enabled for the instruction. The same flag sub-register can be both the predication source and conditional destination, if both predication and conditional modifier are enabled.
	21:19	**ChanOff** Format: **ChanOff** This field provides offset information for ARF selection. The can be thought of as a starting channel offset for the execution mask and other ARF registers implicitly accessed.
	18:16	**ExecSize** Format: **ExecSize** This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.
	15:0	**Header** Format: **Header**

Addition with Carry

addc - Addition with Carry

Source:	Eulsa
Length Bias:	4
Predication:	true
Conditional Modifier:	true
Saturation:	false
Source Modifier:	false

The addc instruction performs component-wise addition of src0 and src1 and stores the results in dst; it also stores the carry into acc. If the operation produces a carry out, 0x00000001 is stored in acc, else 0x00000000 is stored in acc.

Format:

```
[(pred)] addc[.cmod] (exec_size) dst src0 src1
```

Restriction

AccWrEn is required.

The accumulator is an implicit destination and thus cannot be an explicit destination operand.

Syntax

```
[(pred)] addc[.cmod] (exec_size) reg reg reg
 [(pred)] addc[.cmod] (exec_size) reg reg imm32
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.chan[n] ) {
         dst.chan[n] = src0.chan[n] + src1.chan[n];
         acc.chan[n] = carry(src0.chan[n] + src1.chan[n]);
     }
 }
```

		Format: RegDataType
	35	**Dst.AddrMode** Format: AddrMode
	34	**Saturate** Format: Saturate
	33	**AccWrCtrl** Format: AccWrCtrl
	32	**AtomicCtrl** Format: AtomicCtrl
	31	**MaskCtrl** Mask Control (formerly Write Enable Control). This field determines if the per channel write enables are used to generate the final write enable. This field should be normally "0".

Value	Name	Description
0	Normal **[Default]**	Normal. Per channel write enable used for final write enable generation.
1	NoMask	NoMask.Skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.

	30	**Reserved**
	29	**CmptCtrl** Format: MBZ Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction **[Default]**	No compaction. 128-bit native instruction supporting all instruction options.
1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

	28	**PredInv** This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl.

		1 | Negative | Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.
	27:24	**PredCtrl** Format: **PredCtrl** This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register.
	23	**FlagRegNum[0]** This field specifies bit[0] of the register number for a flag register operand.
	22	**FlagSubRegNum** This field specifies the sub-register number for a flag register operand. There are two sub-registers in the flag register. Each sub-register contains 16 flag bits. The selected flag sub-register is the source for predication if predication is enabled for the instruction. It is the destination to store conditional flag bits if conditional modifier is enabled for the instruction. The same flag sub-register can be both the predication source and conditional destination, if both predication and conditional modifier are enabled.
	21:19	**ChanOff** Format: **ChanOff** This field provides offset information for ARF selection. The can be thought of as a starting channel offset for the execution mask and other ARF registers implicitly accessed.
	18:16	**ExecSize** Format: **ExecSize** This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.
	15:0	**Header** Format: **Header**

Arithmetic Shift Right

asr - Arithmetic Shift Right

Source:	Eulsa
Length Bias:	4
Predication:	true
Conditional Modifier:	true
Saturation:	true
Source Modifier:	true

Perform component-wise arithmetic right shift of the bits in src0 by the shift count indicated in src1, storing the results in dst. If src0 has a signed type, insert copies of src0's sign bit in the number of MSBs indicated by the shift count. Otherwise insert 0 bits. When src0 is accumulator and/or source modifier is used with src0 the sign bit is inserted in MSBs which come from the additional precision. **Note**: For Word and DWord operands, the accumulators have 33 bits.
In QWord mode, the shift count is taken from the low six bits of src1 regardless of the src1 type and treated as an unsigned integer in the range 0 to 63. Otherwise the shift count is taken from the low five bits of src1 regardless of the src1 type and treated as an unsigned integer in the range 0 to 31. The operation uses QWord mode if src0 or dst has the Q or UQ type but not if src1 is the only operand with the Q or UQ type. For positive values, this operation is src0 / 2shiftCount and for negative values, this operation is src0 / 2shiftCount - 1.

Format:

```
[(pred)] asr[.cmod] (exec_size) dst src0 src1
```

Programming Notes

If src0 is -1, the result is -1 regardless of the shift count.

For unsigned src0 types, asr and shr produce the same result.

Syntax

```
[(pred)] asr[.cmod] (exec_size) reg reg reg
 [(pred)] asr[.cmod] (exec_size) reg reg imm32
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.channel[n] ) {

         shiftCnt = src0 or dst has Q or UQ type ? src1.chan[n] & 0x3F : src1.chan[n] &
0x1F
         if (src0.chan[n] >= 0) {
             dst.chan[n] = src0.chan[n] » shiftCnt;
         } else {
             int maskLSB = pow(2, shiftCnt) - 1;
             if ( maskLSB & src0.chan[n] == 0 ) {
                 dst.chan[n] = sign(src0.chan[n]) * ((abs)src0.chan[n] » shiftCnt);
             } else {
                 dst.chan[n] = sign(src0.chan[n]) * ((abs)src0.chan[n] » shiftCnt) - 1;
             }
         }
```

asr - Arithmetic Shift Right

```
        }
    }
```

AVP_BSD_OBJECT

AVP_BSD_OBJECT

Source: VideoCS

Length Bias: 2

The AVP Pipeline is selected with the **Media Instruction Opcode "8h"** for all AVP Commands. Each AVP command has assigned a media instruction command as defined in DWord 0, BitField 22:16.

The AVP_BSD_OBJECT command sends to HW a tile at a time from an AV1 bitstream, starting with the first coded byte of the tile, not including the prefixed tile byte size. The bit stream of a tile, tile group, and of a frame may end with trailing bits and extra padding zero bytes. The prefixed tile byte size includes all the trailing bits and padding zero bytes at the end of a tile.
Each tile's coded/compressed bitstream is started and ended at a byte boundary.
HW is not required to parse the trailing bits and padding zero bytes. HW can stop processing right after it has completed the decoding of the last block in the tile. Potentially, error checking can be implemented to detect the trailing bits and padding zeros, but is not implemented in this generation of AVP Pipeline.
here can be multiple tiles in an AV1 frame and thus this command can be issued multiple times per frame. A coded frame minimum has at least 1 tile definition, i.e., a tile can cover the entire frame, unless the frame size exceeds the max allowed tile size limits in pixels, then the frame must contain more than 1 tile. There is no compressed header in AV1, hence AVP_BSD_OBJECT command is only used to process the bitstream of each individual tile of a frame.
The AVP_BSD_OBJECT command must be the last command issued in the sequence of batch commands before the AVP Pipeline starts decoding. Prior to issuing this command, it is assumed that all configuration parameters needed by the AVP Pipeline have been loaded in a specific order, including workload configuration registers and configuration tables. When this command is issued, the AVP Pipeline is waiting for bitstream data to be presented to its bitstream input shift register.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h PARALLEL_VIDEO_PIPE Format: OpCode
	28:27	**Pipeline Type** Default Value: 2h Format: OpCode
	26:23	**Media Instruction Opcode** Default Value: 3h Codec/Engine Name Format: OpCode Codec/Engine Name = AV1 = 3h
	22:16	**Media Instruction Command** Default Value: 20h AVP_BSD_OBJECT_STATE Format: OpCode
	15:12	**Reserved** Access: RO

AVP_BSD_OBJECT

		Format: MBZ
	11:0	**Dword Length** Format: =n (Excludes Dwords 0, 1). **Value** / **Name** 1h
1	31:0	**Tile Indirect BSD Data Length** Format: U32 It specifies the compressed bitstream byte size of a tile. Each tile is started and ended at a byte boundary. It has the same value as the prefixed tile byte size read from the bitstream at the beginning of a tile. The Data Length does not include this prefixed tile byte size, but does include any zero padding bytes at the end of a tile. Error Checking : 1) only when tile bitstream has run out when the last block of the current tile has not been decoded. Set the error bit in MMIO, and perform error concealment to fill in the missing decoded block(s). 2) there is no checking when there are bytes remaining after the last block of the current tile has been decoded. Note : HW AVP decoding pipeline is not required to parse the trailing bits and padding zeros at the end of a tile, tile group, and of a frame.

Value	Name	Description
[1,4294967295]	Tile_Bitstream_Data_Length	It has a valid range of 1 to 4294967295 (2^32-1) bytes. Zero byte length is not allowed. 2^31 should be sufficient to handle a 16Kx16K,12-bit,4:4:4 frame size with a compression ratio of 1. Note : different bitstream LEVELs are having different requirement on the minimum compression ratio.

2	31:0	**Tile Indirect Data Start Address** Format: U32 Specifies the byte-aligned graphics memory starting address of a tile in the bitstream of a frame relative to the **BSD Indirect Object Base Address**. Each tile's coded bitstream is started and ended at a byte boundary. A frame with multiple tiles is coded as one bitstream. Indirect Data Start Address for each tile is equivalent to an address offseted from the starting address of the frame bitstream.

AVP_IND_OBJ_BASE_ADDR_STATE

AVP_IND_OBJ_BASE_ADDR_STATE

Source: VideoCS

Length Bias: 2

The AVP Pipeline is selected with the **Media Instruction Opcode "8h"** for all AVP Commands. Each AVP command has assigned a media instruction command as defined in DWord 0, BitField 22:16.

The AVP_IND_OBJ_BASE_ADDR_STATE command is used to define the indirect object base address of the AV1 compressed bitstream in graphics memory. This is a frame level command issued in both encoding and decoding processes.
Although a frame is coded as separate tiles, all tiles' compressed bitstream are still required to line up sequentially as one AV1 bitstream. Hence, there is only one Indirect Object Base Address for the entire AV1 coded frame. If the frame contains more than 1 tiles, the BSD Object Command will be issued multiple times, once for each tile and with its own tile bitstream starting memory address.

DWord	Bit	Description
0	31:29	**Command Type** Default Value: 3h PARALLEL_VIDEO_PIPE Format: OpCode

AVP_INLOOP_FILTER_STATE

AVP_INLOOP_FILTER_STATE

Source: VideoCS

Length Bias: 2

The AVP_INLOOP_FILTER_STATE command provides all the frame level syntax elements and derived parameters that are needed for the processing of all the post in-loop filters present in the AV1 codec, except the Luma and Chroma x0_qn which are tile based derived parameters. This includes the Deblocker, the CDEF (Constrained Directional Enhancement Filter), the HSRF (Horizontal-only Super-Resolution Filter), and the LRF (Loop Restoration Filter). These syntax elements can be changed in the bitstream from frame to frame.

All Post In-Loop Filters are inherently frame-based filtering, but when implemented in a HW pipeline, the filtering process is performed in tile based and in a block by block fashion. In the addition to these frame and tile level states, there are additional syntax elements and derived parameters that are generated at SuperBlock level, and are not described here.

Each of these 4 Post In-Loop Filters can be controlled independently and each can be enabled or disabled independently. Except the HSRF, all the other 3 filters have separate controls for each color plane as well. To disable a Post In-Loop Filter, its control parameter(s) are set to 0 - the default state.

This command should be issued once per tile, even if no post in-loop filter is enabled for decoding the current frame. When in frame lossless mode or when IntraBC is enabled, all the Post In-Loop Filters are disabled for all color planes, this command will provide the default values for all parameters. All syntax elements are then assumed a value of 0, except otherwise specified in each field of this State Command.

When it is in monochrome video, no filter parameter for the two chroma planes is present in the bitstream.

AVP_INLOOP_FILTER_STATE

	11:0	**Dword Length** Format: =n (Excludes Dwords 0, 1). Value: Dh; Name:
1	31	**Deblocker Filter Delta LF Present Flag** Format: U1 set to 1, specifies that additional loop filter delta values are present at the superblock level in the bitstream. set to 0, specifies that no additional loop filter delta values are present at the superblock level in the bitstream. It is the frame level syntax element delta_if_present flag. It is present in the bitstream, only if delta_q_present is set to 1. If delta_q_present is set to 0, delta_lf_present flag is not present, and is defaulted to 0.
	30	**Deblocker Filter Delta LF Multi Flag** Format: U1 set to 1, specifies that at the Superblock level, separate loop filter deltas (mulitple deltas)are sent for 1) horizontal Luma Y edges, 2) vertical Luma edges, 3) both horizontal and vertical Chroma U edges, and 4) for both horizontal and vertical Chroma V edges. set to 0, specifies that at the Superblock level, the same loop filter delta is used for all edges of all color planes (Y, U and V). It is the frame level syntax delta_lf_multi. It is present in the bitstream, when delta_lf_present flag is set to 1. If delta_lf_present flag is set to 0,delta_lf_multi flag is not present, and is defaulted to 0.
	29:28	**Deblocker Delta LF Resolution** Format: U2 It specifies the number of left shift which should be applied to decoded loop filter delta values. It is in the range of [0..3]. (no shft, and therefore no scaling). It is theframe level syntax element delta_lf_res. It is present in the bitstream, when delta_lf_present flag is set to 1. If delta_lf_present flag is set to 0,delta_lf_resis not present, and is defaulted to 0. Note : it is used to derive one part of the final filter levels: lvl +=read_delta_lflevel() * (1 « delta_lf_res). Note :But in the reference C model, the same name is used for the derived parameter: delta_lf_res = 1 « (delta_lf_res), which can take a 4-bit of value[1, 2, 4 or 8] instead.
	27	**Deblocker Filter Mode Ref Delta Enable Flag** Format: U1

		set to 1, means that the filter levels depends on the mode and reference frame used to predict a block. set to 0, means that the filter level does not depend on the mode and reference frame. Default is 0. It is the frame level syntax elementloop_filter_delta_enabled, or named asmode_ref_delta_enabled.
	26:24	**Deblocker Filter Sharpness Level** Format: U3 It specifies the sharpness level of the deblocker. It is used to compute the deblocker filter limits (lim and mblim) for each of the 64 possible values of a filter level.The deblocker filter levels and the deblock filter sharpness together determine when a block edge is filtered, and by how much the filtering can change the sample values. It is the frame level syntax elementloop_filter_sharpness, or named as sharpness_level. It is in the range of [0..7]. Default is 0.
	23:18	**Chroma V Deblocker Filter Level** Format: U6 It specifies the deblocker filter strength for both the horizontal (using vertical filters) and the vertical (using horizontal filters) edges of the Chroma Vplane. It is the frame level syntax element loop_filter_level[3], or named as filter_level_v.It is present, [only if filter_level[0] and filter_level[1] are not both set to 0 AND only if the current frame is not a monochrome]. If not present, it is default to 0. It is in the range of [0..63]. Default is 0.
	17:12	**Chroma U Deblocker Filter Level** Format: U6 It specifies the deblocker filter strength for both the horizontal (using vertical filters) and the vertical (using horizontal filters) edges of the Chroma U plane. It is the frame level syntax element loop_filter_level[2], or named as filter_level_u. It is present, [only if filter_level[0] and filter_level[1] are not both set to 0 AND only if the current frame is not a monochrome].If not present, it is default to 0. It is in the range of [0..63]. Default is 0.
	11:6	**Luma Y Deblocker Filter Level Horizontal** Format: U6 It specifies the deblocker filter strength for the horizontal edges (using vertical filters) of the Luma plane. It is the frame syntax element loop_filter_level[1]. It is in the range of [0..63]. Default is 0. Settingloop_filter_level[0] =loop_filter_level[1] = 0, disables the deblocker filter.

AVP_INLOOP_FILTER_STATE

	5:0	**Luma Y Deblocker Filter Level Vertical** Format: U6 It specifies the deblocker filter strength for the vertical edges (using horizontal filters) of the Luma plane. It is the frame syntax element loop_filter_level[0]. It is in the range of [0..63]. Default is 0. Settingloop_filter_level[0] =loop_filter_level[1] = 0, disables the deblocker filter.
2	31	**Reserved** Access: RO Format: MBZ
	30:24	**Deblocker Filter Ref Deltas[3]** Format: S6 It is in 7-bits 2's complement within the range of [-64to +63]. Initialize to 0 bysetup_past_independence(). If this syntax element is not present in the bitstream (i.e. update_ref_delta=0), Deblocker Filter Ref Deltas[Ref=0 to 7] maintains its value from previous frame. 	5:0	**CDEF UV Strength[4]** Format: U6 Refer to the full description in CDEF UVStrength[0].
9	31:21	**Reserved** Access: RO Format: MBZ
	20:16	**Super-Res Denom** Format: U5 It specifies an integer denominator of a fixed point fractional number (scaling factor) which is used to scale down the current frame width (in pixels) for the subsequent block level decoding process of its bitstream. Super-resolution is only applied to the horizontal direction, so this scaling factor is applied to the frame width only. The numerator of this down-scaling factor is always set to 8. The reduced (scaled down) frame width in pixels = (upscaled frame width in pixels * 8 + (super-res denom»1)) / super-res denom. This divsion is done by Driver. It is derived from the 3-bits frame level syntax element, coded_denom. Super-res denom = coded_denom + 9, which is always > 8 (i.e. downscaling factor is always < 1.0). That is, the super-resolution down-scaling factor can go from [8/9 to 8/16], and the corresponding up-scaling factor can go from [9/8 to 16/8]. If super-resolution is not enabled, super-res denom is not present in the bitstream,its valueis defaulted to 8 (i.e no scaling). Hence, Super-Rest Denom is in the range of [8.. 16]. Value 0 to 7 are not allowed. Different frames in a video sequence can have different super-res denom. Adjacent frames can all have different super-res denoms. Super-res denom is used in multiple functions of the Super-resolution and the Loop Restoration processes, but no fixed-point division is needed.

		Note : if not monochrome video, the same scaling factor and super-resolution process are applied to the two chroma planes as well; otherwise, only the Luma plane is being processed. Following restrictions apply in Encoder Mode if Wiener Filter enabled: In Single pipe: Only valid values are 10, 12, 14 and 16 In Multi pipe: Only valid value is 16 otherwise all values are valid..
	15:0	**Super-Res Upscaled Frame Width Minus1** Format: U16 It specifies the super-resolution upscaled frame width in pixels, without padding on the right and bottom of the frame. Since, super-resolution is only applied to the horizontal frame width, there is no scaling to the vertical frame height. The input and output of the Loop Restoration Filter and all reference frames in the Display Buffer (DPB) are in Super-Res Upscaled Frame Width. When super-resolution is enabled, the bitstream is coded with the reduced frame width. Hence, the current frame width programmed in the AVP_PIC_STATE is the derived reduced frame width without padding on the right and bottom border of the frame. The scaled downframe width (AVP_PIC_STATE frame width minus1 + 1)= (upscaled frame width * 8 + (super-res denom»1)) / super-res denom. Upscaled frame width is derived as follows: A) In KEY FRAME or INTRA-ONLY NON-KEY FRAME: 1) when frame_size_override_flag is set to 1, it is the frame level syntax element frame_width_minus1. 2) when frame_size_override_flag is set to 1, it is the sequence level syntax element max_frame_width_minus1. B) In INTER FRAME: 1) if the current frame size can be inferred from one of the 7 possible reference frames, it is the derived frame width minus1. Otherwise, 2) when frame_size_override_flag is set to 1, it is the frame level syntax element frame_width_minus1. 3) when frame_size_override_flag is set to 1, it is the sequence level syntax element max_frame_width_minus1. Max frame size is 64K, but intel only support up to 16K. Hence, bit 14 and 15 are not used. Default is 7, for minimum frame width is 8 pixels. Note : if upscaling factor > 1.0, AVP_PIC_STATE Frame Width must < 16K. Note : both the upscaled frame width and the downscaled frame width are provided to the AVP HW pipeline, so that HW does not need to perform the division in the scaling process.
10	31:11	**Reserved** Access: RO Format: MBZ
	10	**Use Same Loop Restoration Unit Size for Chromas UV Flag** Format: U1 It specifies how the Chroma UV Loop Restoration Unit size should be derived from that of the

		Luma. Chroma U and Chroma V are having the same LRU Size. Set to 1, if Chroma LRU size is the same as that of the Luma. Set to 0, if Chroma LRU size is subsampled that of the Luma in 4:2:0 by half in each dimension. Default is 0. It is the frame level syntax element, lr_uv_shift, which is present only if current video is a 4:2:0 and not both Chroma plane having filter type set to RESTORE_NONE. For 4:2:2 and 4:4:4, LRU size for Chromas UV is always the same as that of Luma. For monochrome, this field is ignored. Intel Encoder PAK only support LRU size = SuperBlock size = 64x64 pixels, this field must also be set to 0.
	9:8	**Loop Restoration Unit Size for Luma Y** Format: U2 It specifies the Loop Restoration Unit size in pixels for Luma Y. Loop Restoration Unit is a squaregrid inthe current frame for each color plane. Each Loop Restoration Unit of a color plane has its own set ofLoop Restoration Filter parameters. It is derived from at most 2 1-bit syntax element (lr_unit_shift) in the frame header which are present only if not all 3 color planes having filter type set to RESTORE_NONE. If all 3 color planes having filter type set to RESTORE_NONE, then Loop Restoration Unit Size for Luma plane is defaulted to 256x256. It is also named as LoopRestorationSize[i=0], or restoration_unit_size for Luma plane. But intel has mapped them to the following code: 0, for 0 size (Default, when LR is not enabled) 1, for 64x64 pixels LRU nominal size. 2, for 128x128 pixels LRU nominal size. 3, for 256x256 pixels LRU nominal size. Intel Encoder PAK only supportLRU size = SuperBlock size = 64x64 pixels. Note : LRU Luma Size cannot < Superblock Size. If Superblock Size is 128x128, LRU Luma Size cannot be 64x64.
	7:6	**Reserved** Access: RO Format: MBZ
	5:4	**Frame Loop Restoration Filter Type for Chroma V** Format: U2 It specifies the Frame Level Loop Restoration Filter Type for the Chroma Vplane. It is derived from 2 bits syntax element (lr_type) in the frame header, if not in a monochrome video. It is also named as framerestorationtype[i=2], orframe_restoration_type for Chroma V plane. It is in the range of [0..3]. For a monochrome video, it is defaulted to 0. 0, for RESTORE_NONE. 1, for RESTORE_WIENER. 2, for RESTORE_SGRPROJ (Dual Self-Guided Projection Filter).

		3, for RESTORE_SWITCHABLE (LRU level choice of NONE, WIENER or SGRPROJ). Each color plane can have its ownFrame Level Loop Restoration Filter Type specification. Note : to disable Loop Restoration Filtering in the current frame, the Frame Restoration Filter Type for all color planes must be set to RESTORE_NONE. Note : that the syntax element lr_type uses a different enum order for the four LR filter types (0 for RESTORE_NONE, 1 for SWITCHABLE, 2 for WIENER, and 3 for SGRPROJ). In Encoder Mode, Loop Restoration Filter is not supported, this field can only be set to RESTORE_NONE.
	3:2	**Frame Loop Restoration Filter Type for Chroma U** Format: U2 It specifies the Frame Level Loop Restoration Filter Type for the Chroma U plane. It is derived from 2 bits syntax element (lr_type) in the frame header, if not in a monochrome video. It is also named as framerestorationtype[i=1], orframe_restoration_type for Chroma U plane. It is in the range of [0..3]. For a monochrome video, it is defaulted to 0. 0, for RESTORE_NONE. 1, for RESTORE_WIENER. 2, for RESTORE_SGRPROJ (Dual Self-Guided Projection Filter). 3, for RESTORE_SWITCHABLE (LRU level choice of NONE, WIENER or SGRPROJ). Each color plane can have its ownFrame Level Loop Restoration Filter Type specification. Note : to disable Loop Restoration Filtering in the current frame, the Frame Restoration Filter Type for all color planes must be set to RESTORE_NONE. Note : that the syntax element lr_type uses a different enum order for the four LR filter types (0 for RESTORE_NONE, 1 for SWITCHABLE, 2 for WIENER, and 3 for SGRPROJ). In Encoder Mode, Loop Restoration Filter is not supported, this field can only be set to RESTORE_NONE.
	1:0	**Frame Loop Restoration Filter Type for Luma Y** Format: U2 It specifies the Frame Level Loop Restoration Filter Type for the Luma plane. It is derived from 2 bits syntax element (lr_type) in the frame header. It is also named as framerestorationtype[i=0], or frame_restoration_type for Luma plane. It is in the range of [0..3]. Default is 0. 0, for RESTORE_NONE. 1, for RESTORE_WIENER. 2, for RESTORE_SGRPROJ (Dual Self-Guided Projection Filter). 3, for RESTORE_SWITCHABLE (LRU level choice of NONE, WIENER or SGRPROJ). Each color plane can have its ownFrame Level Loop Restoration Filter Type specification. Note : to disable Loop Restoration Filtering in the current frame, the Frame Restoration Filter Type for all color planes must be set to RESTORE_NONE. Note : that the syntax element lr_type uses a different enum order for the four LR filter types (0 for RESTORE_NONE, 1 for SWITCHABLE, 2 for WIENER, and 3 for SGRPROJ). In Encoder Mode, Loop Restoration Filter is not supported, this field can only be set to

AVP_INLOOP_FILTER_STATE

		RESTORE_NONE.
11	31:16	**Reserved (for higher precision of x_step_qn)** Format: MBZ
	15:0	**Luma Plane x_step_qn** Format: U16 Derived parameter, specifies the increment of the super-res luma upscaling step in pixel position for the current frame.
12	31:0	**Luma Plane x0_qn** Format: S31 Derived parameters, specifies the starting offset (in 2's complement signed integer) of the super-res upscaling process for each tile in the original frame for Luma.
13	31:16	**Reserved** Access: RO Format: MBZ
	15:0	**Chroma Plane x_step_qn** Format: U16 Derived parameter, specifies the increment of the super-res chroma upscaling step in pixel position for the current frame.
14	31:0	**Chroma Plane x0_qn** Format: S31 Derived parameters, specifies the starting offset (in 2's complement signed integer) of the super-res upscaling process for each tile in the original frame for chroma.

Length Bias: 2

The AVP Pipeline is selected with the **Media Instruction Opcode "8h"** for all AVP Commands. Each AVP command has assigned a media instruction command as defined in DWord 0, BitField 22:16.
AVP supports a 8-reference frames display buffer. But at any given frame being decoded, only up to 7reference frames out of the 8 can be active. There are also further constraints on which of these 7frames can be used for forward and backward reference in the compound mode.
To simplify the decoder command sequence programming, this command is issued once for each inter-coded tile as well as for each intra-coded tile (such as in a KEY_FRAME, a DELAY_KEY_FRAME, an INTRA_ONLY_FRAME).

AVP_PIC_STATE

AVP_PIC_STATE

Source: VideoCS

Length Bias: 2

All AVP_PIC_STATE should stay the same for the whole frame even if AVP_PIC_STATE is re-programmed for every tiles.
The bitfields of AVP_PIC_STATE are defined either from
1) syntax elements of the uncompressed sequence header (received from sequence_header_obu) and of the uncompressed frame header (received from frame_header_obu),
2) or, parameters derived from 1).
Note : Bitstreams may contain several copies of the frame header (there can only be one frame_header_obu, but multiple redundant_frame_header_obu)interspersed with tile_group_obu to allow for greater error resilience. However, the copies must contain identical contents to the original frame_header_obu.
Note : there should be only one sequence_header_obu per video sequence.
Note : AVP pipeline is invoked to decode a frame from the bitstream, only if that frame has show_existing_frame flag (syntax element in the frame header) set to 0. For the case thatshow_existing_frame flag is set to 1, application and driver process the frame instead, no block level decoding is needed.
Note : Unlike VP9, AV1 does not have a compressed header. All the syntax elements defined in the AV1 sequence and frame level headers are not arithmetic coded, hence application and driver can directly read them off from the bitstream.
Note : the values of the sequence header/level syntax elements and their derived parameters are to last throughout all frames in the video sequence, until the next Sequence Header OBU is received that may change them. But some sequence header/level syntax elements or their derived parameters may further qualified by frame header/level syntax elements and their derived parameters, then these type of syntax elements and their derived parameters can be changed frame to frame.
Note : the values of the frame header/level syntax elements and their derived parameters can be changed from frame to frame.
Note : there are some syntax elements and their derived parameters can be changed only at KEY FRAME. Hence, the values of these type of syntax elements and their derived parameters can last for the entire GOP, i.e. until the next KEY FRAME that may change them.
Note : there is no separate profile for Still Picture. Still Picture is coded and decoded as a KEY FRAME, with all coding tools supported (tiling, all post in-loop filters, film grain injection, monochrome, intraBC, palette prediction mode, etc.). There is no restriction in coding Still Picture as a KEY FRAME.

	11:0	**Dword Length** Format: =n (Excludes Dwords 0, 1). Value / Name / Programming Notes: 31h – Decoder DW Length – Only Up to DW12 should be programmed for decoder 48h – Encoder DW Length – All DWs should be programmed for encoder
1	31:16	**Frame Height In Pixel Minus 1** Format: U16 Specifies the height of the frame to be decoded in unit of pixel. It is the same as the frame height in luma samples. AV1 supports up to 64Kx64K frame size. Intel supports up to 16Kx16K frame size. Valid range [15, 16383]. Min frame height is 16pixels. Hence, Luma is 16and Chroma is 8(in 4:2:0). It is a frame-level derived parameters, after taking into account of the syntax elementmax_frame_height in the sequence header and frame_size_override_flag in the frame header. For SWITCH Frame,frame_size_override_flag is always set to 1; for all other frame types (KEY Frame, INTRA-ONLY Frame and INTER Frame),frame_size_override_flag is read from the bitstream (and can be 0 or 1).For inter-frame, it also takes into account of the possibility of using frame size inferred from a reference frame. Note : this field is not affected by Horizontal Super-Resolution coding. Note : this frame height may be odd or even number, and may not be divisible by 4, 8 , superblock size, tile size, or LRU size. Note : if frame height is an odd number, the corresponding height of the Chroma planes in 4:2:0 is rounded up. For example, if Luma height is 13 pixels, Chroma height is 7 pixels. Note : internally the frame height is rounded up to be divisible by 8 in both the HW encoder and decoder. The padding in the encoder side is not normative, but will be coded into the bitstream. When decoder reconstructs the decoded frame from the bitstream, the padding is being reconstructed as well. The padding at the right and bottom borders of the decoded frame can be cropped away before display. But they are not cropped away when the decoded frame is added into the DPB as a reference frame. Note : this is NOT the Render Frame Height, which is used to crop the decoded frame size for display.

AVP_PIC_STATE

	15:0	**Frame Width In Pixel Minus 1** Format: U16 Specifies the width of the decoded frame in unit of pixel. It is the same as the frame width in uma samples. AV1 supports up to 64Kx64K frame size. Intel supports up to 16Kx16K frame size. Valid range [15, 16383]. Min frame width is 16pixels. Hence, Luma is 16and Chroma is 8(in 4:2:0). It is a frame-level derived parameters, after taking into account of the syntax elementmax_frame_width in the sequence header and frame_size_override_flag in the frame header. For inter-frame and s-frame, it also takes into account of the possibility of using frame size inferred from a reference frame. When the Horizontal Super-Resolution is active, this frame width is the downscaled frame width. Note : if Horizontal-Only Super-Resolution is ON, this field specifies the reduced width of the downscaled frame size. The number of Superblocks to be processed per row in this case is derived from this reduced frame width. The tile configuration is also specified in this reduced frame width. But after deblocker and CDEFfiltering (if either or both are active), this reduced frame width is scaled back up to the original frame width for the subsequent Loop Restoration filtering (if active), which then is outputted for display or become a reference frame. Hence, all reference frames in the DPB are always stored in full frame resolution, and dynamic on-the-fly frame resizing is always invoked during Motion Comp at block level, which is coded with the reduced frame width. Note that the upscaled frame width cannot exist 16K range. upscaling frame width = reduced frame width * upscaling factor. The upscaled frame width is provided in the AVP_INLOOP_FILTER_STATE Command. Note that this frame width may be odd or even number, and may not be divisible by 4, 8 , superblock size, tile size, or LRU size. Note : if frame width is an odd number, the corresponding width of the Chroma planes in 4:2:0 is rounded up. For example, if Luma width is 13 pixels, Chroma width is 7 pixels. Note : internally the frame width is rounded up to be divisible by 8 in both the HW encoder and decoder. The padding in the encoder side is not normative, but will be coded into the bitstream. When decoder reconstructs the decoded frame from the bitstream, the padding is being reconstructed as well. The padding at the right and bottom borders of the decoded frame can be cropped away before display. But they are not cropped away when the decoded frame is added into the DPB as a reference frame. Note : this is NOT the Render Frame Width, which is used to crop the decoded frame size for display.

AVP_PIC_STATE

21 **Sequence Enable Joint Compound Flag**

Format:	U1

It specifies whether the Joint Compound coding tool is enabled for the video sequence, or not.
It is the sequence level syntax element, enable_jnt_comp, which is only present in the bitstream when the sequence level syntax element enable_order_hint is set to 1. It is defaulted to0, whenenable_order_hint is set to 0.

Value	Name	Description
0h	**[Default]**	Indicates that the distance weights process is NOT used for inter prediction.
1h		Indicate that the distance weights process may be used for inter prediction.

20 **Sequence Enable Masked Compound Flag**

Format:	U1

It specifies whether the Masked Compound coding tool is enabled for the video sequence, or not.
It is the sequence level syntax element, enable_masked_compound.
Valid only in Decoder Mode

Value	Name	Description
0h	**[Default]**	Indicates that the mode info for inter blocks do NOT contain the block level syntax element compound_type and others.
1h		Indicates the block level syntax elements: compound_type and others, are present in the bitstream.

19 **Sequence Enable Inter-Intra Compound Flag**

Format:	U1

It specifies whether the Inter-Intra Compound coding tool is enabled for the video sequence, or not.
It is the sequence level syntax element, enable_interintra_compound.
Valid in Decoder Mode only

Value	Name	Description
0h	**[Default]**	Indicates that the mode info for inter blocks do NOT contain the block level syntax element interintra and others.
1h		Indicates that the block level syntax elements: interintra and others, are present in the bitstream.

18 **Sequence Enable Dual_Filter Flag**

Format:	U1

It specifies whether the Motion Comp horizontal and vertical interpolation filters are specified independently in the bitstream at the block level (inter-coded block)or not, for the video sequence.
Set to 0 ; indicate only ONE MC filter type is specified in the bitstream, which is then used in both directions . (Default)
Set to 1 ; indicate the MC filter type may be specified independently in the horizontal and vertical directions.
It is the sequence level syntax element, enable_dual_filter.
Note : MC filter type can be [EIGHTTAP, EIGHTTAP_SMOOTH, EIGHTTAP_SHARP, BILINEAR, and

		SWITCHABLE]. Must be set to 0 in encoder mode
	17	**Sequence Enable Intra Edge Filter Flag** Format: U1 It specifies whether the Intra Edge Filtering process is enabled for the video sequence or not. Set to 0 ; indicate that the Intra Edge Filter tool is DISabled. (Default) Set to 1 ; indicate that the Intra Edge Filter tool is ENabled. It is the sequence level syntax element, enable_intra_edge_filter.
	16	**Sequence Enable Filter_Intra Flag** Format: U1 It specifies if the Filter_Intra coding tool is enabled for the video sequence. Set to 0 ; indicate the block level syntax element: use_filter_intra, is NOT present in the bitstream. (Default) Set to 1 ; indicate the block level syntax element: use_filter_intra, is present in the bitstream. It is the sequence level syntax element, enable_filter_intra. Note : if both enable_filter_intra and use_filter_intra are set to 1, the corresponding block is coded with filter_intra Must be set to 0 in encoder mode
	15:13	**Reserved (for the expansion of Sequence Order Hint Bits Minus1)** Format: MBZ
	12:10	**Sequence Order Hint Bits Minus1** Format: U3 It specifies the number of bits to be read from the bitstream for the frame header syntax elements: order_hint and ref_order_hint[i=0 to 6]. It is in the range of [0..7] . It is the sequence level syntax element, order_hint_bits_minus1, which is only present in the bitstream if the sequence level syntax element enable_order_hint_flag is set to 1. It is defaulted to 0, if not present. It can be used to generate the bitmask in computing the relative distance between two order hints. Note: it is also used for other purposes, as detail in the bitfield Sequence Enable Order Hint Flag.
	9	**Sequence Enable Order Hint Flag** Format: U1 Set to 1 ;enables the use of Order Hint in the decoding process of all INTER frames in the video sequence. Set to 0 ; disables the use of Order Hint. (Default) It is the sequence level syntax element, enable_order_hint. It controls 1) the bitstream reading of the syntax elements: enable_jnt_comp, enable_ref_frame_mvs, and

		order_hint_bits_minus1 in the sequence header. 2) the bitstream reading of the syntax elements: ref_order_hint[i=0 to 6] and frame_refs_short_signaling in the frame header. 3) the setting of reference frames in the frame header for the decoding of the current frame. Note : these 2 sequence level syntax elements: enable_order_hint flag and the 3-bits order_hint_bits_minus1 are used in : 1) skip_mode derivation, 2) compound prediction temporal weighing factor derivation, 3) motion field estimation process and MV projection, 4) motion_field MV storage setting, 5) reference frame bias derivation, 6) forward, second_forward, and backward reference frame selection, 7) and forward, second_forward and backward reference frame order hint setting.
	8:7	**Sequence Superblock Size Used** Format: U2 It specifies one of the two possible Superblock sizes that is used to code the video sequence. Set to 0, if the SuperBlock size is 64x64 pixels. (Default) Set to 1, if the SuperBlock size is 128x128 pixels. Value 2-3 are reserved. It is the sequence level syntax element, use_128x128_superblock; and is also named as sb_size. Supports SB size 64x64 only in encoder mode
	6	**Reserved** Access: RO Format: MBZ
	5	**Reserved (for expansion of Sequence Pixel Bit-Depth Idc)** Format: MBZ
	4:3	**Sequence Pixel Bit-Depth Idc** Format: U2 It specifies the pixel bit depth for all frames in the video sequence being decoded. [4:3] = 00 ; specifies 8-bit per pixel (bpp). (Default) [4:3] = 01 ; specifies 10-bit per pixel. [4:3] = 10 ; specifies 12-bit per pixel It is a sequence-level parameter derived from the sequence header syntax elements:seq_profile,high_bitdepth and twelve_bit. Note : Only Bit-Depth = 8 and 10 are allowed for this generation of AVP. Note : refer to the description under Sequence Chroma Sampling Format for detail on allowed bit depth for each profile.
	2	**Reserved (for expansion of Chroma SubSampling Format)** Format: MBZ

AVP_PIC_STATE

	1:0	**Sequence Chroma SubSampling Format** Format: U2 It specifies the chroma subsampling format for all frames in the video sequence being decoded. [1:0] = 00 ; stands for Monochrome 4:0:0, no Chroma planes at all, but [subsampling_x and subsampling_y] is defaulted to [1, 1], as only Profile 0 can support monochrome video coding. [1:0] = 01 ; stands for 4:2:0, with[subsampling_x and subsampling_y] defining as[1, 1]. It is supported in all profiles (seq_profile=0, 1, 2 - syntax element in the sequence header) [1:0] = 10 ; stands for 4:2:2, with[subsampling_x and subsampling_y] defining as[1, 0]. It is supported only in seq_profile=2. [1:0] = 11 ; stands for 4:4:4 with[subsampling_x and subsampling_y] defining as[0, 0]. It is supported in both seq_profile=1 and 2. It is a sequence-level parameter derived from the sequence header syntax elements: seq_profile, subsampling_x, subsampling_y, monochome, high_bitdepth and twelve_bit. Default is 1, i.e. 4:2:0.. Note : AV1 supports 3 profiles: seq_profile Bit_depth Chroma Subsampling 0 (Main Profile) 8 / 10 YUV 4:2:0 and 4:0:0 1 (High Profile) 8 / 10 YUV 4:4:4 (4:0:0 is not allowed) 2 (Pro Profile) 8 / 10 /12 YUV 4:2:2 AND 12 YUV 4:2:0/4:4:4/4:0:0 Note : for AV1 decoder: • A profile 0 compliant decoder must be able to decode all bitstreams labeled profile 0 • A profile 1 compliant decoder must be able to decode all bitstreams labeled profile 0 or 1 • A profile 2 compliant decoder must be able to decode all bitstreams labeled profile 0, 1, or 2 "01" -- Chroma Sampling 4:2:0 is supported. **Value** / **Name** / **Description** 1h / 4:2:0 / Chroma Sampling 4:2:0
3	31	**Reserved (for future expansion of Primary Reference Frame Idx)** Format: MBZ
	30:28	**Primary Reference Frame Idx** Format: U3 It specifies which one of the 7 possible reference frames [reference frame ID0 to 6]contains the frame context(CDF table set for all syntax elements) and other state that should be loaded at the start of the frame. The normal range of values for Primary Reference Frame is [0 to 6]. The value of 7 (defined as PRIMARY_REF_NONE) is used to signal when there is no primary reference frame. It is the frame level syntax element, primary_ref_frame, which is present in the bitstream when (! FrameIsIntra && ! error_resilient_mode). If it is not present in the bitstream, it is defaulted to PRIMARY_REF_NONE (=7).

		There is no primary reference frame: 1) if (FrameIsIntra || error_resilient_mode). Hence only INTER Frame and SWITCH Frame can have primary reference frame ID specified in the bitstream when not in error resilient mode. 2) Or when it receives a value of 7from the bitstream. Note : load_cdfs(ref_frame_idx[primary_ref_frame])is a function call that indicates that the frame context (CDF table set)is loaded from the frame context attached to one of the 8 possible reference frames in the DPB. Note : load_previous( ) is a function call that indicates that information from a previous frame may be loaded for use in decoding the current frame. Note : if (primary_ref_frame == PRIMARY_REF_NONE), it is required to set segmentation_update_map = 1 , segmentation_temporal_update = 0 , and segmentation_update_data = 1. Note : If primary_ref_frame is set to PRIMARY_REF_NONE, it is a requirement of bitstream conformance that loop_filter_delta_update is equal to 1.
	27:24	**Reserved** Access: RO Format: MBZ
	23	**Allow IntraBC Flag** Format: U1 It specifies whether intra block copy prediction mode is allowed to be used in the current frame or not. Set to 0 to disallow intra block copy prediction mode. (Default) Set to 1 to allow intra block copy prediction mode. It is the frame level syntax element, allow_intrabc. It is present in the bitstream, only if the sequence syntax element allow_screen_content_tools is set to 1 AND there is no super-resolution frame width scaling (but super-resolution can still be enabled). When it is not present in the bitstream, it is defaulted to 0. Note : intra block copy is only allowed in KEY Frame and INTRA-ONLY Non-Key Frame. For all other frame types (INTER Frame and SWITCH Frame), this flag is set to 0. Note : when this flag is set to 1, all post in loop filters (deblocker, CDEF, Super-Resolution and Loop Restoration) are all disabled. Note : when this flag is set to 1, force_integer_mv is set to 1 in KEY Frame and INTRA-ONLY Non-Key Frame. Valid only in Decoder Mode
	22	**Error Resilient Mode Flag** Format: U1 It specifies whether all syntax decoding of the current frame is independent of the previous frames, or not. Set to 0 to disable error resilient mode Set to 1 to enable error resilient mode (for independent syntax decoding) It is the frame-level syntax element, error_resilient_mode. Default is 0. It is read from the bitstream for all frame types (KEY Frame, INTRA-ONLY Frame and INTER

Frame), except when frame_type is set to SWITCH_FRAME, in which it is forced to 1 instead of reading from the bitstream.
When error resilient mode is set to 1 (active), Refresh Frame Context is set to0. When error resilient is set to 0, Refresh Frame Context is read from the bit stream.
Valid only in Decoder Mode

Value	Name
0	Disable
1	Enable

21:20 **Reserved**

Access:	RO
Format:	MBZ

19 **IntraOnly Flag**

Format:	U1

It specifies if the current frame being decoded is a KEY Frame or a INTRA-ONLY Non-Key Frame. It is a derived parameter from the frame level syntax element, frame_type, and is also named as FrameIsIntra.
IntraOnly Flag = (frame_type == INTRA_ONLY_FRAME) || (frame_type == KEY_FRAME).

18 **Reserved (for the expansion of Frame Type)**

Format:	MBZ

17:16 **Frame Type**

Format:	U2

Specifies one of the four possible AV1 frame types.
[17:16] = [00] ; specifies KEY Frame. (Default)
[17:16] = [01] ; specifies INTER Non-Key Frame.
[17:16] = [10] ; specifies INTRA-ONLY Non-Key Frame.
[17:16] = [11] ; specifies SWITCH Non-Key Frame (or called S-Frame, is a different type of INTER Frame).
It is the frame level syntax element, frame_type.
Note: Encoder does not support INTRA-ONLYand S-Frame

15:14 **Reserved**

8:7 **Reserved**

Access:	RO
Format:	MBZ

	6	**Frame Level Loop Restoration Filter Enable Flag** Format: U1 It specifies whether the Post In-Loop Loop Restoration Filter tool is enabled for the current frame, or not. Set to 0 ; indicate that the Loop Restoration Filter is DISabled for the current frame.(Default) Set to 1 ; indicate that the Loop Restoration Filter is ENabled for the current frame. Frame Level Loop Restoration Filter Enable Flag is an intel derived parameter, and is set to 1 whenLuma frame_restoration_type != RESTORE_NONE || Chroma Cb frame_restoration_type != RESTORE_NONE || Chroma Cr frame_restoration_type != RESTORE_NONE; It is derived from 1) the sequence level syntax element, enable_restoration, 2) the frame level derived coding parameters : frame level all_lossless and allow_intrabc, 3) and also the frame level syntax for loop restoration filter type of each color component. Although Use Loop Restoration Filter Flag = ! (AllLossless || allow_intrabc || !enable_restoration) can be used to signal thedisabling ofthe loop restoration filter for the current frame, it is still possible at the frame level to read in the loop restoration filter type syntax elements that indicate the loop restoration filter is not enabled. To simplify hardware, this field is used to give HW the derived final decision if the loop restoration filter is enabled or not. When Large Scale Tile Enable flag is set to 1, this Loop Restoration Filterflag must set to 0, to disable the loop restoration filtering completely. Note : When individual frames in a video sequence are coded in Alllossless or with intraBC enabled, all post in-loop filtering processes (deblocker, CDEF, horizontal super-res, and loop restoration) should be disabled. Note : When Loop Restoration filter is disabled, all its filter types should be programmed to RESTORE_NONE.
	5	**Use Super-Res Flag** Format: U1 It specifies whether the Post In-Loop Horizontal-Only Super-Resolution tool is enabled for the current frame being decoded, or not. Set to 0 ; indicate that the Super-Res Frame Upscaling process is NOT performed. This sequence level setting cannot be overridden. (Default) Set to 1 ; indicate that the Super-Res Frame Upscaling process is to be performed. But this sequence level setting can be overridden when in frame coded lossless or when intraBC is enabled. It is derived from the sequence level syntax element, enable_superres, from the frame level syntax element of the same name: use_superres, and from the frame level derived coding parameters : frame coded_lossless and allow_intrabc. If the frame level syntax element of the same name, use_superres is not present in the bitstream, it is defaulted to 0. When Large Scale Tile Enable flag is set to 1, this Use Super-Res flag must set to 0, to disable super-resolution coding method. Note : it is legal to set the sequence level syntax element: enable_superresequal to 1, even when use_superres is set to 0 (i.e. no superres is performed)on all frames in the coded video sequence. Note : When individual frames in a video sequence are coded in coded_lossless or with intraBC enabled, all post in-loop filtering processes (deblocker, CDEF, horizontal super-res, and loop restoration) should be disabled.

		Note : When Super-res is disabled, the Denom of the scaling factor should be set to 8 (to have the same value as the default NUMERATOR).
	4	**Use CDEF Filter Flag** Format: U1 It specifies whether the Post In-Loop CDEF Filter tool is enabled for the current frame being decoded, or not. Set to 0 ; indicate that the CDEF Filter is DISabled. This sequence level setting cannot be overriden. (Default) Set to 1 ; indicate that the CDEF Filter is ENabled. But this sequence level setting can be overridden when in frame-level coded lossless or when intraBC is enabled. It is derived from the sequence level syntax element of the same name, enable_cdef and the frame level derived coding parameters : coded_lossless and allow_intrabc. Use CDEFFilter Flag = ! (Codedlossless|| allow_intrabc || !enable_cdef). When Large Scale Tile Enable flag is set to 1, this Use CDEF Filter flag must set to 0, to disable CDEF Filtering operation completely. Note : it is legal to set enable_cdef equal to 1 even when cdef filtering is not used on any frame in the coded video sequence. Note : When individualframes in a video sequence are coded in lossless or with intraBC enabled, all post in-loop filtering processes (deblocker, CDEF, horizontal super-res, and loop restoration) should bedisabled. Note : When CDEF filter is disabled, all its filter parameters should be reset to 0.
	3	**Reserved** Access: RO Format: MBZ
	2	**Allow Warped Motion Flag** Format: U1 Set to 0 ; indicates that the block level syntax element: motion_mode is NOT present in the bitstream. Hence, the block cannot signal for LOCALWARP coding. Set to 1 ; indicates that the block level syntax element: motion_mode is present in the bitstream. It is the frame level syntax element, allow_warp_motion, which is present in the bitstream only if thiscondition is met: (! FrameIsIntra && ! error_resilient_mode && enable_warped_motion). If it is not present in the bitstream, it is defaulted to 0. Note : motion_mode can take on a value of [SIMPLE. OBMC, or LOCALWARP]. LOCALWARP not supported in encoder mode
	1	**Force Integer MV Flag** Format: U1 Set to 0 ; indicates that motion vectors used in the Motion Comp can contain fractional bits (sub-pel precision). (Default) Set to 1 ; indicates that motion vectors used in the Motion Comp is always integers (NO sub-pel precision for Luma only). It is derived from thesequence level syntax elements: seq_choose_screen_content_tools

		andseq_force_screen_content_tools, and from the frame level syntax element : allow_screen_content_tools.
		if (allow_screen_content_tools = =1) AND (seq_force_integer_mv = = 2), read the value of force_integer_mv flag from the bitstream (in the frame header).
		If(allow_screen_content_tools = =1) AND (seq_force_integer_mv != 2) , force_integer_mv flag is set to the value of seq_force_integer_mv (which is read from the bitstream in the sequence header).
		if(allow_screen_content_tools = =0) , force_integer_mv is set to0.
		Note : for 4:2:0 and 4:2:2, the chroma subsampling factors (subsampling_x and subsampling_y) are also applied to the Luma MVs. Hence, integer Luma MVs will still give half-pel precision Chroma MVs (i.e. with fractional bit).
		Note : if intraBC is enabled, force_integer_mv is always set to 1 in the intra frames (KEY Frame or Intra-Only Non-Key Frame).
		Note : when force_integer_mv is set to 1, some fractional bits are still read for the translation components. However, these fractional bits will be discarded during the Setup Zero MV process.
		Valid only in decoder Mode

	0	**Allow Screen Content Tools Flag** Format: U1 Set to 0 ; indicates that the two block level screen content coding tools (palette prediction coding and intraBC coding). (Default) Set to 1 ; indicates that the block level syntax element: motion_mode is present in the bitstream. It is derived from thesequence level syntax elements: seq_choose_screen_content_tools andseq_force_screen_content_tools, and from the frame level syntax element of the same name: allow_screen_content_tools. ifseq_choose_screen_content_tools = = 1, read the value of allow_screen_ccontent_tools from the bitstream (in the frame header). Ifseq_choose_screen_content_tools = = 0, allow_screen_content_tools is set to the value of seq_force_screen_content_tools (which is read from the bitstream in the sequence header). Note : at the frame header, allow_screen_content_tools flag controls the setting of intraBC and integer_mv coding tools, but at the block level, it controls the use of the palette prediction coding mode. Valid in Decoder Mode only
4	31	**Reserved** Access: RO Format: MBZ
	30:24	**Y_dc_delta_q** Format: S6 **Programming Notes** 2's complement sign number of range -63 to +63.

AVP_PIC_STATE

	23:16	**Base Qindex** Format: U8 It can take on value range from 0 to 255. This is the same as the Y_ac_q, becasue y_ac_delta_q is always set to 0.
	15:14	**Reserved** Access: RO Format: MBZ

	13	**Segment ID Buffer Stream-Out Enable Flag**
		Format: U1
		It indicates if the processing of the current frame requires to write out the segment IDs at the block level to a segment ID Buffer.
		It is set to 1, if stream-outis going to happen.
		It is set to 0, if stream-outis not going to happen at all.
		It is an intel derived frame level parameters based on only frame level syntax and other derived parameters. Its meaning is defined as follows:
		if(SegmentIdStreamOutFlag)
		{
		HW needs to write out segment ID to Segment ID Write Buffer;
		}
		else
		{
		HW does not need to write out segment ID;
		}
		Driver is responsible to set this Segment ID Buffer Stream-Out Enable Flag based on the following conditions (using Driver variable names) :
		Frame Level derived parameter : (seg->enable = = 1) &&
		Frame Level SE : seg->update_map = = 1
		Valid in Decoder only Mode

	12	**Segment ID Buffer Stream-In Enable Flag**
		Format: U1
		It indicates if the processing of the current frame requires to read in the segment IDs at the block level from a segment ID Buffer.
		It is set to 1, if stream-in is going to happen.
		It is set to 0, if stream-in is not going to happen at all.
		It is an intel derived frame level parameters based on only frame level syntax and other derived parameters. Its meaning is defined as follows:
		Valid in Decoder only Mode
		if (SegmentMapIsZeroFlag)
		{
		Segment ID is all 0s.
		Driver wlill programSegmentIdStreamInFlagto 0. (HW checks on the SegmentMapIsZeroFlag=1, and set all temporal segment ID to 0)

}
else if (SegmentIdStreamInFlag)
{
Segment ID is streamed in from Segment ID read buffer;
}
else
{
No Segment ID stream-in
}
Driver is responsible to set this Segment ID Buffer Stream-InEnable Flag based on the following conditions (using Driver variable names) :
Frame Level derived parameter : (seg->enable = = 1) &&
Frame Level SE : (primary_ref_frame != PRIMARY_REF_NONE) &&
Frame Level derived parameters :
((seg->update_map = = seg->temporal_update = = 1) ||
(seg->update_map = = seg->temporal_update = = 0)) &&
((DPB[current_frame].resolution = = DPB[primary_ref_frame].resolution) &&
(DPB[primary_ref_frame].seg_enable) &&
(DPB[primary_ref_frame].segment_ID_buffer != NULL))

11 **Segment Map Is Zero Flag**

Format:	U1

In a video sequence or within a GOP,some frames can have segmentation disabled. Their corresponding segment map is defaulted to have its content set to all 0. If later, this all zero segment map will be referenced by HW for temporal segment map prediction, it will be a waste of bandwidth to read in zeros.
Segment Map Is Zero flag is an intel added parameter at frame level.
If it is set to 1, ittells HW that the segment map is containing all zero. AVP HW will check this bit together with if segment map streamin is enabled, then HW will not actually read from the segment map buffer, but will internally generate the read of 0 instead, to save bandwidth.
Driver needs to keep track of which reference frame(s) (max 7) have segmentation disabled for decoding the current frame,and set this flag accordingly.
Driver is responsible to set this Segment Map Is Zero Flag based on the following conditions (using Driver variable names) :
Frame Level derived parameter : (seg->enable = = 1) &&
Frame Level SE : (primary_ref_frame != PRIMARY_REF_NONE) &&
Frame Level derived parameters :
((seg->update_map = = seg->temporal_update = = 1) ||
(seg->update_map = = seg->temporal_update = = 0)) &&
! [((DPB[current_frame].resolution = = DPB[primary_ref_frame].resolution) &&
(DPB[primary_ref_frame].seg_enable) &&
(DPB[primary_ref_frame].segment_ID_buffer != NULL))]

10 **Frame Coded Lossless Mode**

Format:	U1

This bitSet to indicate lossless coding mode at frame level.
Frame Coded Lossless Mode is set to 1, if all active segment's segment lossless flag are set to 1.
The equation for deriving coded lossless mode is presented in the AVP_SEGMENT_STATE Command.
AllLossless = CodedLossless && (FrameWidth == UpscaledWidth). The second condition in this equation is equivalent tohaving Super-res NOT enabled.
Only CodedLossless flag is sent to HW. AllLossless flag is not.
CodedLossless directly control the enabling/disabling of deblocker, CDEF in-loop filters.
But AllLossless is used to control the enabling/disabling of Loop Restoration filter. Hence, when super-res is ON, Loop Restoration filter can still be ON/OFF, regardless of CodedLossless.

Value	Name
0	Normal Mode
1	Coded Lossless Mode

9:8 **Delta Q RES**

Format:	U2

if delta_q_present_flag = 1, 2 bits from bitstream are read.
Delta_q_res = 0, 1, 2 and 3.
and the mulitple factor= 1 « (delta_q_res) = [1, 2, 4 or 8].
Here, only the 2 bits are programmed to the HW.

7 **Delta Q Present Flag**

Format:	Enable

if delta_q_present_flag = 1, delta_q_res is present in the bitstream - to specify SB level delta q.
In encoder mode, this flag must be set to 1 for BRC purpose so the QP can be changed at SB level.
However, it can be set to 0 for CQP across frame

6:4 **Last Active Segment ID**

Format:	U3

It specifies the highest numbered segment id that has some enabled feature. This is used when decoding the segment id to only decode choices corresponding to used segments.

3 **Pre-Skip Segment ID Flag**

Format:	U1

Set to 1 indicates that the segment id will be read before the skip syntax element. SegIdPreSkip equal to 0 indicates that the skip syntax element will be read first.

2 **Segmentation Temporal Update Flag**

Format:	U1

Indicates whether segID is decoding from bitstream or predicted from previous frame.
In encoder Mode it should use either from previous frame or streamIn

Value	Name
0h	Decode segID from bitstream
1h	Get segID either from bitstream or from previous frame

Programming Notes
Decoder Only: For KEY_FRAME or INTRA_ONLY frame [OR ERROR_RESILIENCE], this bit should be set to "0". [Temporary add in the condition ERROR_RESILIENCE, to be removed later] Note: Driver should override this flag to "0" in KEY_FRAME or INTRA_ONLY frame even if this bit decoded from bitstream is different. This is for hardware optimization. This override does not affect bitstream decoding other than uncompressed header.

1 **Segmentation Update Map Flag**

Format:	U1

Set to 0 means that the segmentation map from the previous frame is used, and the current frame decode is not changing the segmentation map. (Default)
Set to 1 means that the segmentation map is updated during the decoding of the current frame. Hence SegmentIDs of current frame arestreamout to a write only surface, which will be used as the segmentation map for a future frame(s).
It is theframe level syntax element, segmentation_update_map. It is present in the bitstream only if, the frame level syntax elements: segmentation is enabled AND primary_ref_frame is NOT PRIMARY_REF_NONE. Ifprimary_ref_frame is set to PRIMARY_REF_NONE, segmentation_update_map is always set to 1.
Note : the segmentation map that has streamout (surface buffer) is attached to the current frame, after it has become a reference frame in the Display Buffer (DPB).
Note : HW needs to detect one of these 3 conditions (the current frame is in error resilient mode OR the current frame type is KEY Frame or INTRA-ONLY Frame), and if TRUE, then HW will not read the segment map for decoding the current frame, all segment ID is considered as 0. But during the decoding of the current frame, the segment map can still be modified is segmentation map update flag is ON.

0 **Segmentation Enable Flag**

Format:	U1

Indicate if segmentation is enabled or not

Value	Name
0h	All blocks are implied to belong to segment 0
1h	SegID determination depends on segmentation_update_map setting

5 31 **Reserved**

Access:	RO
Format:	MBZ

30:24 **V_ac_delta_q**

Format:	S6

AVP_PIC_STATE

		Programming Notes 2's complement sign number of range -63 to +63.

	27:24	**Reserved (for future expansion of Frame Order Hint)** Format: MBZ
	23:16	**Current Frame Order Hint** Format: U8 It specifies "OrderHintBits" least significant bits of the expected output order for the current frame being decoded. It is the frame level syntax element, order_hint. Default value is 0. Order_hint is a variable bit length syntax element; its bit length is in the range of

		OrderHintBits=[1..8]. Hence, maximum order_hint can have a value of 255. Note: There is no requirement that OrderHint should reflect the true output order.
	15:8	**Reference Frame Sign Bias [i=0 to 7]** Format: U8 This is a bit array that specifies the Reference Frame Sign Bias for Reference 0 to 7 (only 1 to 7 are valid, OR 0 to 6 ???) Reference Picture 0 is INTRA frame and there is no sign bias for it. Bit 9 : Last Frame (Reference Picture 1) Bit 10: Last2 Frame (Reference Picture 2) Bit 11: Last3 Frame (Reference Picture 3) Bit 12: GoldenFrame (Reference Picture 4) Bit 13: Bwdref Frame (Reference Picture 5) Bit 14: Altref2 Frame (Reference Picture 6) Bit 15: Altref Frame (Reference Picture 7) It is a frame-level derived parameter for each reference frame, RefFrameSignBias[i=0 to 7]. 1-bit per reference frame. It is derived from the frame level parameters order hint and ref order hints. If the sequence syntax element enable_order_hint is set to 0, RefFrameSignBias[i=0 to 7] are all set to 0.
	7	**Use Reference Frame MV Set Flag** Format: U1 Set to 0, specifies that motion vector information from a previous frame (stored inside the temporal MV buffer) CANNOT be used when decoding the current frame. (Default) Set to 1, specifies that motion vector information from a previous frame can be usedwhen decoding the current frame. It is the frame level syntax element, use_ref_frame_mvs, which is present in the bitstream only if the sequence level syntax elements: enable_order_hint and enable_ref_frame_mvs are both set to 1 and the frame level syntax element: error_resilient_mode is set to 0. If it is not present in the bitstream, it is defaulted to 0.
	6	**Motion Mode Switchable Flag** Format: U1 Set to 0, specifies only SIMPLE motion mode can be used. (Default) Set to 1, specifies the motion mode being used is determined at the block level. It is the frame level syntax element, is_motion_mode_switchable. It is present only in INTER Frame or SWITCH Frame. For all other frame types (KEY Frame and INTRA-ONLY Frame), it is defaulted to 0. Note :Motion Mode for motion comp can be SIMPLE, OBMC or LOCALWARP.
	5	**Reserved (for future expansion of Mcomp Filter Type)** Format: MBZ

AVP_PIC_STATE

	4:2	**Mcomp Filter Type** Format: U3 It specifies which Motion Compensation Filter type is to be used for the current frame. It is a frame-level derived parameters. It is derived from the frame level syntax elements (is_filter_switchable flag and the 2-bits interpolation_filter). Default is 0 (i.e. use the eight-tap basic filter). **Value** / **Name** 0h – Eight-tap 1h – Eight-tap-Smooth 2h – Eight-tap-Sharp 3h – Bilinear 4h – Switchable **Programming Notes** In VDENC mode, setting Switchable results in Eight-tap filter across the whole frame.
	1	**Frame Level Reference Mode Select** Format: U1 Set to 0 specifies that all inter blocks in the current frame will use single prediction (SINGLE_REFERENCE). Default is 0, use SINGLE_REFERENCE. Set to 1 specifies that the frame level prediction mode for inter blocks is REFERENCE_MODE_SELECT, which will cause reading the syntax element comp_mode at PartU level to specify whether to use single or compound reference prediction for that partU. It is the frame level syntax element, reference_select. If it is NOT present in the bitstream, it is defaulted to 0.
	0	**Allow High Precision MV** Format: U1 It specifies whether the high precision MV mode is used for the Luma Motion Vector prediction or not. Set to 0, specifies that motion vectors are in quarter-pel precision. (Default, the normal mode) Set to 1, specifies that motion vectors are in eighth-pel precision. It is the frame-level syntax element, allow_high_precision_mv. It is present in the bitstream, only if the frame level parameter force_integer_mv is set to 0. If it is not present in the bitstream, it is default to 0.
7	31:24	**Reference Frame Side [i=0 to 7]** Format: U8 This is a bit array that specifies the Reference Frame Sidefor Reference 0 to 7. Bit 24: Intra Frame (Reference Picture 0) Bit 25: Last Frame (Reference Picture 1) Bit 26: Last2 Frame (Reference Picture 2) Bit 27: Last3 Frame (Reference Picture 3)

		Bit 28: GoldenFrame (Reference Picture 4) Bit 29: Bwdref Frame (Reference Picture 5) Bit 30: Altref2 Frame (Reference Picture 6) Bit 31: Altref Frame (Reference Picture 7) It is a intel frame-level derived parameter for each reference frame, For each reference frame the corresponding bit is set to 0 when the corresponding bit in ref_frame_side is 0, else the bit will be set to 1. Each individual bit (i=0 to 7)of the original reference frame side parameter can take on a value of -1, 0, or 1. But intel version of the same parameter can only take on a value of 0 or 1. Both the original value of -1 and1 is mapped to 1 here, and the original value of 0 remains mapped to 0. Default all 8-bits are set to 0.
	23:13	**Reserved** Access: RO Format: MBZ
	12	**Reserved (for future expansion of Skip Mode Frame[1])** Format: MBZ
	11:9	**Skip Mode Frame [1]** Format: U3 It specifies the reference frames to use for compound prediction when skip_mode is set to 1. It is the frame level derived parameter SkipModeFrame[1]. Skip mode tries to use the closest forward (past) and backward (future) references (as measured by values in the RefOrderHint array). If no backward reference is found, then the second closest forward reference is used. If no forward reference is found, then skip mode is disabled.
	8	**Reserved (for future expansion of Skip Mode Frame[0])** Format: MBZ
	7:5	**Skip Mode Frame [0]** Format: U3 It specifies the reference frames to use for compound prediction when skip_mode is set to 1. It is the frame level derived parameter SkipModeFrame[0]. Skip mode tries to use the closest forward (past) and backward (future) references (as measured by values in the RefOrderHint array). If no backward reference is found, then the second closest forward reference is used. If no forward reference is found, then skip mode is disabled.
	4	**Skip Mode Present Flag** Format: U1 Set to 0 specifies that skip_mode will not be used for this frame. Default is 0, no PartU level skip flag. Set to 1 specifies that the syntax element skip_mode will be coded in the bitstream at the PartU level. It is the frame-level syntax element skip_mode_present. It is present in the bitstream based on an algorithm using RefOrderHint. If it is not present in the bitstream, it is defaulted to 0.

AVP_PIC_STATE

	3	**Reserved** Access: RO Format: MBZ
	2:1	**Frame Transform Mode** Format: U2 It specifies the Luma-only transform size to be used for the entire current frame to be decoded. 1) tx_mode=0 for ONLY_4X4, if the current frameis coded with frame coded lossless and only Hadamard 4x4 transform is being used for the whole frame. This is also applied to Chroma planes as well. 2) tx_mode=1 for TX_MODE_LARGEST, the inverse transform will use the largest transform size that fits inside the block. 3) tx_mode=2 for TX_MODE_SELECT, the choice of transform size is specified explicitly for each block. It is the frame-level derived parameters, TxMode. It is derived from the frame-level syntax element, tx_mode_select and the frame level derived parameter Frame Coded Lossless. Default is TxMode=1. Chroma Tx Mode is no longer derived from that of Luma Tx size. Chroma Tx Mode has no explicit setting in the bitstream,andChroma Tx Mode can be viewed as always equivalent to TX_MODE_LARGEST for the two Chroma planes.
	0	**Reduced Tx Set Used** Format: U1 **Programming Notes** set to 1 to allow the use of a reduced tx set. set to 0 to allow the full tx set to be used for each tx type. It is the frame level syntax element, reduced_tx_set.
8	31:24	**Frame Level Global Motion Invalid Flags** Format: U8 It indicates to the AV1 HW pipeline (at block level processing) that the result of parsing the frame level global motion parameters of each reference frame is invalid or not. Each bitrepresents the invalid flag of a reference frame : it is set to 1, if the global motion parameters for the corresponding reference frame is invalid. Otherwise it is set to 0 for valid (default). Frame Level Global Motion Invalid Flags[31] indicates the validity of reference frame ALTREF. ... Frame Level Global Motion Invalid Flags[25] indicates the validity of reference frame LAST. Frame Level Global Motion Invalid Flags[24] indicates the validity of reference frame INTRA (this bit is reserved and not being used by HW)... This is an intel defined parameter to give HW a hint of frame header parsing result that cansimplify the HW design. It takes on the same value as of theglobal_motion[ALTRF...LAST].invalid flag, which is set insideread_global_motion() function of the reference C model.

	23	**Reserved (for future expansion of Global Motion Type[7]** Format: MBZ
	22:21	**Global Motion Type[7]** Format: U2 It specifies the global motion type associated with each reference [LAST_FRAME ... ALTREF_FRAME] that can be used to decode the current frame. Set to 0, specifies IDENTITY(requires no additional warp projection parameter) Set to 1, specifies TRANSLATION (requires 2 additional warp projection parameters) Set to 2, specifies ROTZOOM (requires 4 additional warp projection parameters) Set to 3, specifies AFFINE (requires 6additional warp projection parameters) It is the frame level derived parameter gmtype[LAST_FRAME ... Length Bias: 2

The AVP Pipeline is selected with the **Media Instruction Opcode "8h"** for all AVP Commands. Each AVP command has assigned a media instruction command as defined in DWord 0, BitField 22:16.

This state command provides the physical memory base addresses for all row store buffers, column store buffers, reconstructed output and reference frame buffers, and auxiliary data buffers (MV, segment map, etc.) that are required by the AV1 decoding and encoding process.
This is a frame level state command and is shared by both encoding and decoding processes.
AVP is a tile based pipeline and is a stateless pipeline, hence all sequence level, frame level, and segment level state commands must be resent to process each tile.
Memory compression may be applicable to some of these buffers for BW saving.
Note : there is no buffer to store the 16 QM table sets, they are implemented directly inside the HW pipeline.

AVP_PIPE_BUF_ADDR_STATE

1..16	511:0	**Reference Frame Buffer Base Address (RefAddr[0-7])** Format: **SplitBaseAddress64ByteAligned[8]** This array specifies the physical memory base addresses of the 8 visible reference frame buffers using for inter-prediction. They all contain previously reconstructed/decoded frames. However, this Reference Frame Buffer array is a remapped version (see below the mapping equations)of the DPB buffer array specified in the AV1 Spec and Reference C Model. Intel implementation has converted the 2 level of reference frame indexing (using RefFrame[0..6] and ref_frame_idx[0..6]) into a single level indexing (using the enumINTRA_FRAME, LAST_FRAME, ..., ALTREF_FRAME, in thisfixed order). In the process, the ref_frame_idx[0..6] array is eliminated by intel. Application and Driver will continue to receive or parse the bitstream header based on the2-level indexing AV1 DPB buffer array definition, which can containmore than 8 frame buffers, but only at most 8 of them are visible to the AVP HW pipeline and is in the formed of single level indexing intel-remapped-DPB array. Typically, these reference frame buffers are read-only, for the purpose of Motion Comp. Memory compression is applied in accessing these buffers. At most only 7 out of the 8 visible reference frames can be used for Motion Comp.in decoding inter-coded blocks of the current frame. The subset of reference frames being used in decoding the current frame is setup by the Application and Driver. But it is recommended to set all Reference Frame Buffer Base Address to valid andknown addresses for error handling. AV1 Reference Frames are defined in the following order: DW 0-1 RefAddr[0] - INTRA Frame (Reference Frame 0) DW 2-3 RefAddr[1] - LAST Frame (Reference Frame 1) In AV1 Spec, it is mapped intoDPB [ref_frame_idx[LAST_FRAME-LAST_FRAME]] DW 4-5 RefAddr[2] - LAST2 Frame (Reference Frame 2) In AV1 Spec, it is mapped intoDPB [ref_frame_idx[LAST2_FRAME-LAST_FRAME]] DW 6-7 RefAddr[3] - LAST3 Frame (Reference Frame 3) In AV1 Spec, it is mapped intoDPB [ref_frame_idx[LAST3_FRAME-LAST_FRAME]] DW 8-9 RefAddr[4] - GOLDEN Frame (Reference Frame 4) In AV1 Spec, it is mapped intoDPB [ref_frame_idx[GOLDEN_FRAME-LAST_FRAME]] DW 10-11RefAddr[5] - BWDREF Frame (Reference Frame 5)In AV1 Spec, it is mapped intoDPB [ref_frame_idx[BWDREF_FRAME-LAST_FRAME]] DW 12-13RefAddr[6] - ALTREF2 Frame (Reference Frame 6)In AV1 Spec, it is mapped intoDPB [ref_frame_idx[ALTREF2_FRAME-LAST_FRAME]] DW 14-15RefAddr[7] - ALTREF Frame (Reference Frame 7) In AV1 Spec, it is mapped intoDPB [ref_frame_idx[ALTREF_FRAME-LAST_FRAME]] Note : for 48 bit address, a pair of Dwords (i.e. 2) are needed to store each base address. Note : This reference frame naming convention is a legacy specification in the reference C model. Although the very first reference frame is labeled as INTRA, it is not reserved only for a previously decoded KEY frame or a decoded INTRA-ONLY NON-KEY frame. Any newly decoded frame can be stored in any one of these 8 reference frame buffers for future reference - it is up to the Application and Driver that handle the DPB management according to the bitstream and normative rules specified in AV1. Note : When IntraBC coding mode is used in the KEY Frame or in the INTRA-ONLY NON-KEY Frame, the intraBC coded block is decoded as a regular inter-coded block, and one of these 8 reference frame buffers will be directly used in a READ/WRITE fashion. ??? Note : the format of the pixels (Y, U and V components)stored inside these reference frame buffers is defined in the AV1_Surface_State Command. For monochrome video, all reference frame buffers can only have Luma Y component. Note :All reference frame buffers' surface addresses must be 4K byte aligned. There is a max. of 8 Reference Picture Buffer Addresses, and all share the same third address DW in specifying 48-

AVP_PIPE_BUF_ADDR_STATE

17	31:0	**Reference Frame Buffer Base Address Attributes** Format: MemoryAddressAttributes All reference frame buffers' surface addresses must be 4K byte aligned. There is a max. of 8 Reference Picture Buffer Addresses, and all share this same third address DW in specifying 48-bit address.
18..19	63:0	**Decoded Output Frame Buffer Address** Format: SplitBaseAddress4KByteAligned It specifies the physical memory base addresses of the frame buffer that stores the final pixel output of the AVP pipeline, just before the Film Grain unit(could be sent for display). Typically, it is a WRITE-only surface with pixel format specified in the AV1_SURFACE_STATE. It can be 4:0:0, 4:2:0, 4:2:2 or 4:4:4. Memory compression is applied to this surface. This buffer holds the result of reconstructing the current frame, including all the Post In-Loop Filtering Processes (Deblocker, CDEF, Super-Resolution, and/or Loop Restoration) that are enabled. There can be a few actions to follow: 1) Application and Driver will then place this newly decoded frame into the Display Buffer (DPB), as one of the 8 reference frames, only if it will be used for the decoding of a later frame(s) (??? a bit in the frame header is set to indicate this ???). 2) At the same time, if this newly decoded frame is to be displayed immediately, it will also be copied and sent to other system for further processing or directly to the Display Controller. 3) If Film Grain Injection is enabled in the sequence header, this newly decoded frame is further processed by the Out of Loop Film Grain Synthesis unit in a block-based pipeline fashion (continued from the block-based pixel reconstruction pipeline of the AV1 decoder). Note: when intraBC is active, it can also be a READ surface for the Motion Comp operation. ??? Note : there is only one write location along the in-loop decoding pipeline, and it is at the output of the Loop Restoration Filter. If any or all of the Post In-Loop Filters (Deblocker, CDEF, Super-Resolution, Loop Restoration)are disabled, the reconstructed pixels still need to pipethrough those disabled filters without change (i.e. simply bypass), until they reach the output of the Loop Restoration Filter. Note : if it is decided to implement some of the Post In-Loop Filters in software (as a separate pass - not being implemented yet), this buffer will hold the final pixel output frame of the HW pipeline. Note : this decoded output buffer if going to be used as a reference frame, then it is added into the Display Buffer (DPB) at the location specified by the frame level syntax element refresh_frame_flags. If the current frame is a KEY Frame or a SWITCH Frame, refresh_frame_flags is set to all 1's, so the entire DPB is initialized (KEY Frame)/re-initialized (SWITCH Frame) to the current frame.

21..23	95:0	**Reserved** Access: RO Format: MBZ

AVP_PIPE_BUF_ADDR_STATE		
24..25	63:0	**IntraBC Decoded Output Frame Buffer Address** Format: **SplitBaseAddress4KByteAligned** When IntraBC (frame level) is ON, the current decoded and reconstructed partial pixel frame is needed for motion compensation. The normal Decoder Output Frame Buffer is typically written out with memory compression ON, as such it is not suitable to be read back for performing motion compensation within the decoding of the same frame. A separate decoded output frame buffer is needed, whose surface buffer does not have memory compression turned ON. That is, when IntraBC is ON (frame level), AVP will write out two decoded output frame with identical content.
26	31:0	**IntraBC Decoded Output Frame Buffer Address Attributes** Format: **MemoryAddressAttributes**
27..28	63:0	**CDF Tables Initialization Buffer Address** Format: **SplitBaseAddress64ByteAligned** Base address for the CDF Tables Initialization Buffer. This Buffer is read-only. It is programmable with the initial CDF table set for the entire frame and for all its tiles at the very beginning before any decoding process. The content of this buffer must be the same for all tiles for the frame
29	31:0	**CDF Tables Initialization Buffer Address Attributes** Format: **MemoryAddressAttributes**
30..31	63:0	**CDF Tables Backward Adaptation Buffer Address** Format: **SplitBaseAddress64ByteAligned** Baseaddress of the CDF Tables Backward Adaptation Buffer. This Buffer stores the updated frame context of the largest tile in the current decoded frame. This is a WRITE-Only buffer.
32	31:0	**CDF Tables Backward Adaptation Buffer Address Attributes** Format: **MemoryAddressAttributes**
33..34	63:0	**AV1 Segment ID Read Buffer Address** Format: **SplitBaseAddress64ByteAligned** Specifies the 64 byte aligned buffer address for AV1 SegmentID buffer. This should contain the writeout SegmentID from previous frame and will be used to predict SegmentID for the current frame. Hardware will write out SegmentID of the current frame in the same address for the next frame. It is used for temporal prediction of segment ID in the current frame. The segment map has a granularity of 4x4 blocks.
35	31:0	**AV1 Segment ID Read Buffer Address Attributes** Format: **MemoryAddressAttributes**

AVP_PIPE_BUF_ADDR_STATE

36..37	63:0	**AV1 Segment ID Write Buffer Address** Format: **SplitBaseAddress64ByteAligned** Specifies the 64 byte aligned buffer address for AV1 SegmentID buffer. This should contain the writeout SegmentID of the current frame and will be used to predict SegmentID for later frame. This segment map buffer is attached to the current decoded frame as its auxiliary data, and are both stored together in the Display Buffer (DPB), if the current frame is to be used as a reference frame to decode later frame(s). The segment map has a granularity of 4x4 blocks.

AVP_PIPE_MODE_SELECT

AVP_PIPE_MODE_SELECT

Source: VideoCS

Length Bias: 2

The AVP Pipeline is selected with the **Media Instruction Opcode "8h"** for all AVP Commands. Each AVP command has assigned a media instruction command as defined in DWord 0, BitField 22:16.

The workload for the AVP pipeline is tile based. Once the bit stream DMA is configured with the AVP_BSD_OBJECT command for a tile in a frame, and the tile's bitstream is presented to the AVP, the tile decoding will begin.
AVP pipeline is stateless, i.e. there is no states saved between the decoding of each tile. Hence all sequence, frame and segment state commands have to be resent before the tile coding command and the BSD object command.
The AVP_PIPE_MODE_SELECT command is responsible for general pipeline level configuration that would normally be set once for a single stream encode or decode and would not be modified on a frame workload basis.
This is a frame level state command and is shared by both encoding and decoding processes.

AVP_SEGMENT_STATE

AVP_SEGMENT_STATE

Source: VideoCS

Length Bias: 2

When segmentation is enabled, this Segment State command is issued once per segment. There can be maximum 8 segments specified to decode a given frame, so this Segment State Command can be issued maximum 8 times. It is assumed that there is no gap in segment IDs. So, when the AVP PIC States specified that the number of active

When segmentation is disabled, driver still sends out this command once for segment id = 0. HW needs to check the segmentation enable flag from AVP_PIC_STATE Command as well to distinguish from the case when segmentation is enabled for segment id = 0.

Each segment can have its own specification of enabling any one of the 8 features defined in AV1 and their corresponding feature data. When a feature is not enabled, its feature data is defaulted to 0. When segmentation is not enabled, all the features are disabled and their corresponding feature data are set to 0.

Segment State Command also provides other segment related parameters.

It is assumed that HW is keeping a copy of the complete AV1 QM Matrix Table for all color components inside its internal memory, and Driver only needs to send the qm_level as index into this Table.

AVP_SEGMENT_STATE

1	31:3	**Reserved** Access: RO Format: MBZ
	2:0	**Segment ID** Format: U3 The Segment ID specifies which one of the 8 possible segments that the current Segment State Command is associated with. Segment ID is in the range of [0 ... 7]. Maximum, there can be 8 segments specified for decoding a given frame. Segment ID=0, even when segmentation is disabled.
2	31:28	**Segment Chroma V QM Level** Format: U4 It specifies one of the 16 QM matrices to be used for the Chroma V component of the current segment. It is in the range of [0..15]. QM Level = 15, is a bypass, with no scaling. Default is 15. If the current segment is coded as lossless or if qm matrix is not enabled (frame level SE : using_qmatrix = = 0), then Segment QM Level is set to 15. Chroma V qmlevel = (segment lossless flag || using_qmatrix == 0) ? 15: qm_v (frame level SE). If separate_uv_delta_q (sequence level SE) is set to 0, Segment Chroma V QM Level is set to the same value as of Segment Chroma UQM Level. If separate_uv_delta_q (sequence level SE) is set to 1, Segment Chroma V QM Level can be set independently to a different value as of Segment Chroma U QM Level. For a given frame, all lossy segments should have the same value for Vqm_level.
	27:24	**Segment Chroma U QM Level** Format: U4 It specifies one of the 16 QMmatrices to be used for the Chroma U component of the current segment. It is in the range of [0..15]. QM Level = 15, is a bypass, with no scaling. Default is 15. If the current segment is coded as lossless or if qm matrix is not enabled ((frame level SE : using_qmatrix = = 0), then Segment QM Level is set to 15. Chroma U qmlevel = (segment lossless flag || using_qmatrix == 0) ? 15: qm_u (frame level SE). For a given frame, all lossy segments should have the same value for Uqm_level.
	23:20	**Segment Luma Y QM Level** Format: U4 It specifies one of the 16 QMmatrices to be used for the Luma Y component of the current segment. It is in the range of [0..15]. QM Level = 15, is a bypass, with no scaling. Default is 15. If the current segment is coded as lossless or if qm matrix is not enabled (frame level SE : using_qmatrix = = 0), then Segment QM Level is set to 15. Luma qmlevel = (segment lossless flag || using_qmatrix == 0) ? 15: qm_y (frame level SE).

		For a given frame, all lossy segments should have the same value forY qm_level.
	19	**Segment Lossless Flag** Format: U1 0 : the current segment is not coded as lossless. Default is 0. 1 : the current segment is coded as lossless. Segment Lossless Flag = (clamp[(base_qindex + optional segment delta qindex), 0, 255] == 0) && (y_dc_delta_q == 0) && (u_dc_delta_q == 0) && (u_ac_delta_q == 0) && (v_dc_delta_q == 0) && (v_ac_delta_q == 0) It is computing using syntax elements all from the bitstream, read in the uncompressed header. In encoder mode, if one of the segments is lossless then all segments must be lossless in the frame.
	18	**Segment Block GlobalMV Flag** Format: U1 It specifies the segment feature data corresponding to the feature id = SEG_LVL_GLOBALMV = 7. Segment Block GlobalMV Flag = 0, specifies nothing. Segment Block GlobalMV Flag = 1, specifies the blocks of the current segment are all coded with Y inter prediction mode set to GLOBALMV. There is no feature data read from the bitstream for setting the Segment Block GlobalMV Flag. It iis derived from it corresponding segment feature mask. Segment Block GlobalMV Flag =seg_feature_mask & (1 « SEG_LVL_GLOBALMV) If Segment Block GlobalMV Flag = 1, The Y inter prediction mode is set to ZeroMV (for using zero MV), and RefFrame[0] (??? elaborate) is set to LAST_FRAME, and RefFrame[1] is set to NONE (-1).
	17	**Segment Block Skip Flag** Format: U1 It specifies the segment feature data corresponding to the feature id = SEG_LVL_SKIP = 6. Segment Block Skip Flag = 0, specifies there is no segment block skip. Segment Block Skip Flag = 1, specifies the blocks of the current segment are all skipped. These blocks are then having all coefficients and MV set to 0 (Y inter prediction mode is set to zeroMV mode), but these blocks can still have coding mode specified in the bitstream. There is no feature data read from the bitstream for setting the Segment Block Skip Flag. It iis derived from it corresponding segment feature mask. Segment Block Skip Flag =seg_feature_mask & (1 « SEG_LVL_SKIP) If Segment Block Skip Flag = 1, no coefficient is present in the bitstream, and are all set to 0. The Y inter prediction mode is set to ZeroMV (for using zero MV), and RefFrame[0] is set to LAST_FRAME , and RefFrame[1] is set to NONE (-1). It is used to derived the skip_mode flag and skip flag.
	16:8	**Segment Delta Qindex** Format: S8 It specifies the segment feature data corresponding to the feature id =SEG_LVL_ALT_Q = 0.

		It is a 9-bit signed 2's complement number, in the range of [-255, +255]. Default is 0. Value -256 is not allowed.
	7:0	**Segment Feature Mask** Format: U8 It is an 8-bit mask specifies which of the 8 segment features are active in the current segment specifications. It is also known as feature enable mask or feature active mask. This mask can indicate 0 or up to 8 features are enabled. Any feature can be active or inactive independent of the other features. seg_feature_mask & (1 « feature_id) = 0, the feature (identified by feature_id) is not enabled/active in the current segment. seg_feature_mask & (1 « feature_id) = 1, the feature (identified by feature_id) is enabled/active in the current segment. Feature_ID (enum)Feature Name 0 SEG_LVL_ALT_Q, // Use alternate Quantizer. 1 SEG_LVL_ALT_LF_Y_V, // Use alternate loop filter value on y plane vertical. 2 SEG_LVL_ALT_LF_Y_H, // Use alternate loop filter value on y plane horizontal. 3 SEG_LVL_ALT_LF_U, // Use alternate loop filter value on u plane. 4 SEG_LVL_ALT_LF_V, // Use alternate loop filter value on v plane. 5 SEG_LVL_REF_FRAME, // Optional Segment reference frame. 6 SEG_LVL_SKIP,// Optional Segment zeroMV (0,0) + skip mode. 7 SEG_LVL_GLOBALMV. // Optional Segment zeroMV (0,0). Each segment has its own seg_feature_mask. When a segment is not being used or when segmentation is disabled, the corresponding seg_feature_mask has all 8-bits set to 0. Default all 8-bits are 0.
3	31	**Reserved** Access: RO Format: MBZ
	30:28	**Segment Reference Frame** Format: U3 It specifies the segment feature data corresponding to the feature id =SEG_LVL_REF_FRAME = 5. It is an alternate specification of one of the 8 possible reference frames for a Motion Compensation. =0 for INTRA_FRAME =1 for LAST_FRAME =2 for LAST2_FRAME =3 for LAST3_FRAME =4 for GOLDEN_FRAME =5 for BWDREF_FRAME =6 for ALTREF2_FRAME =7 for ALTREF_FRAME It is in the range of [0..7]. Default is 0.

AVP_SEGMENT_STATE		
	27:21	**Segment Delta Loop Filter Level Chroma V** Format: S6 It specifies the segment feature data corresponding to the feature id =SEG_LVL_ALT_LF_V= 4. It is associated with filter_level_v read from the uncompressed header. It is a 7-bit signed 2's complement number, in the range of [-63, +63]. Default is 0.
	20:14	**Segment Delta Loop Filter Level Chroma U** Format: S6 It specifies the segment feature data corresponding to the feature id =SEG_LVL_ALT_LF_U= 3. It is associated with filter_level_u read from the uncompressed header. It is a 7-bit signed 2's complement number, in the range of [-63, +63]. Default is 0.
	13:7	**Segment Delta Loop Filter Level Luma Horizontal** Format: S6 It specifies the segment feature data corresponding to the feature id =SEG_LVL_ALT_LF_Y_H= 2. It is associated with filter_level[1] read from the uncompressed header. It is a 7-bit signed 2's complement number, in the range of [-63, +63]. Default is 0.
	6:0	**Segment Delta Loop Filter Level Luma Vertical** Format: S6 It specifies the segment feature data corresponding to the feature id =SEG_LVL_ALT_LF_Y_V = 1. It is associated with filter_level[0] read from the uncompressed header. It is a 7-bit signed 2's complement number, in the range of [-63, +63]. Default is 0.

AVP_SURFACE_STATE

AVP_SURFACE_STATE

Source: VideoCS

Length Bias: 2

The AVP Pipeline is selected with the **Media Instruction Opcode "8h"** for all AVP Commands. Each AVP command has assigned a media instruction command as defined in DWord 0, BitField 22:16.

The AVP_SURFACE_STATE command is responsible for defining the frame buffer pitch and the offset of the chroma component.
This is a picture level state command and is shared by both encoding and decoding processes.
For Decoder, this command is issued once per surface type. There is one reconstructed surface, 8 reference pictures surfaces and one optional IntraBC Decoded Surface (only if IBC is ON).
For Encoder, this command is issued once per surface type. There are4 surface types :source down scaled, source original, reference and reconstructed picture. All reference frames are defined with the same surface command.
Tile-Yf and Tile-Ys are not supported, but HW interface still need to keep these bits as reserved bits.
Note : When NV12 and Tile Y are being used, full pitch and interleaved UV is always in use. U and V Xoffset must be set to 0; U and V Yoffset must be 8-pixel aligned. For 10-bit pixel, P010 surface definition is being used.

Bh	AV1 Bwdref Frame	This is for AV1 Bwdref Frame (Reference Picture 5). Each AV1 Reference Pictures can have different size so a separate ID is needed.	
Ch	AV1 Altref2 Frame	This is for AV1 Altref2 Frame (Reference Picture 6). Each AV1 Reference Pictures can have different size so a separate ID is needed.	
Dh	AV1 Altref Frame	This is for AV1 Altref Frame (Reference Picture 7). Each AV1 Reference Pictures can have different size so a separate ID is needed.	
Eh	IntraBC Decoded Frame	This is for AV1 IntraBC Decoded Frame. It will be used both Read/Write at the same time. This surface requires multiple of 8 pixels on both width and height.	This surface must be programmed as uncompressed

	27:17	**Reserved** Access: RO Format: MBZ
	16:0	**Surface Pitch Minus1** Format: U17-1

This field specifies the surface pitch in (#Bytes - 1).

Programming Notes
For TileYF and TileYS surfaces, the range is dependent on the Cu parameter (refer to Memory Data Formats section for the definition of the Cu parameter depending on the case). The range in bytes is [2^{Cu}-1, 131071] -> [(2^{Cu})B, 128KB] = [1 tile, 128KB/(2^{Cu}) tiles] The field specifies the surface pitch in (#Bytes - 1)
For tiled surfaces, the pitch must be a multiple of the tile width (i.e.128 bytes aligned). If Half Pitch for Chroma is set, this field must be a multiple of two tile widths for tiled surfaces, or a multiple of 2 bytes for linear surfaces. For Y-tiled surfaces: Range = [127, 131071] to [128B,128KB] = [1 tile, 1024 tiles]

2 — 31:27 — Surface Format

Format:	U5

Specifies the format of the surface.
P010V is only applied to the Surface Id=Fh (AV1 CDEF pixels streamout), encoder only. And also the 2 LSBs are removed, so this P010V surface is actually an 8-bit surface.

Value	Name

AVP_TILE_CODING

AVP_TILE_CODING

Source: BSpec

Length Bias: 1

Programming Notes

This command is used only for AV1codec. It is issued for every tile of a frame. If a frame is composed of only 1 tile, it is still being issued. Tiling and Tile Group organization in AV1 cannot be disabled, a frame minimum must have 1 tile. Currently, each batch buffer can contain only 1 tile to be processed, it cannot contain more than 1 tile or the entire tile group of tiles.

When the tile width exceeds 4096 pixels or the tile area exceeds 4096x2304 pixels, tiling must be performed and number of tiles in such frame must be >1. There is no mandatory tiling driven by tile height. The frame height in pixels will limit the allowed tile height in extreme situation. Hence, the AVP_TILE_CODING can be issued multiple times for decoding a frame.

Since AVP HW pipeline is stateless, all sequence, frame and segment level states (coding parameters in all Frame Level State Commands) must be resent before sending each TILE_CODING_STATE command.

Although tile size is specified in SuperBlock unit, the minimum tile size is actually set to be 8x8 pixels (which is the same as the minimum frame size in pixels). It can also happen to the rightmost tile column and bottommost tile row of a frame which is not divisible by the SuperBlock size - this leads to the presence of partial tile and partial SuperBlock handling.

AV1 supports both

1) a uniform-spacing tiling scheme (as in VP9, which is always in the form of 2^N x 2^M number of tiles, for the entire frame), and

2) a non-uniform-spacing tiling scheme. Bitstream syntax elements will specify the width and height of each tile size in the frame.

AVP HW pipeline is a tile-based codec engine, it does not need to distinguish between these two tiling schemes. Driver will take care of the difference and details of these tiling schemes. At the end, Driver will send out one tile at a time with all the related tile information to the HW through this TILE_CODING State Command.

In AV1, a frame is partitioned by tile row and tile column. That is, a tile boundary must go across the full frame width or the full frame height only. There is no tiling within a tile.

For AV1, the max number of tiles per frame is set to 256 in the LEVEL definition for regular video decoding. The ext-tile (Virtual Reality mode, currently not supported) has a different tiling configuration, constraints and definition.

AVP_TILE_CODING

	22:16	**Media Instruction Command** Default Value: 15h AVP_TILE_CODING Format: Opcode
	15:12	**Reserved** Access: RO Format: MBZ
	11:0	**Dword Length** Format: U12 Excludes Dwords 0 & 1 Value: 4h — Name: **[Default]**
1	31:24	**Tile Group ID** Format: U8 It specifies the Tile Group the current tile belongs to. It is intel specific parameter, not present in the AV1 bitstream. Each tile is belonging to a Tile Group, and there can be multiple TGs in a frame. All TGs of a frame are lined up in raster order within the frame. Each TG is received from the bitstream as a separate TG_OBU. So, a frame can receive multiple TG_OBUs. Currently, all TG_OBUs of a frame must be received in the correct sequential order (not arbitrary order is defined yet). A TG can start at any tile position of a frame (e.g. at the beginning of a tile row, in the middle of a tile row, or at the end of a tile row). A TG does not break by the frame width, and can continue to the next row of tiles below. A TG can span multiple tile rows. A TG can end at any tile position of a frame(e.g. at the beginning of a tile row, in the middle of a tile row, or at the end of a tile row). A TG can be viewed as a linear chain of tiles (not necessary a 2-D rectangular/square region of a frame). A TG can maximum contain the whole frame of tiles, or minimum contain only a single tile of the frame. A frame can be entirely coded as a single tile in a single TG. Each TG is assigned an unique ID number, in raster increasing order. This numbering is intel specific, not defined in the spec. There is no jump or gap in TG ID value between two adjacent TG. The top-left most tile of a frame is always has TG ID = 0. The bottom-right most tile of a frame is always has the highest TG ID value. Tile Group ID is in the range [0..255]. The max value 255 is intel specific. Note : the max number of TG per frame is set equal to the max number of tiles allowed in a frame, since each tile can belong to a different TG.
	23:12	**TG Tile Num** Format: U12 Specify the Tile Number inside a Tile Group. This numbering is intel specific, not present in the AV1 bitstream. All tiles of a TG are numbered in sequential raster order, starting from 0. TG Tile Num is reset at each TG boundary. That is, the very first tile of a TG is always assigned a TG Tile Num of 0. The last tile of a TG has the largest Tile Num of that TG. So, the total number of tiles in a frame = (the largest Frame Tile ID + 1) = sum for all TG [largest

		TG Tile Num+ 1]. Max number of tiles in a TG is currently limited to 128 at the highest level 6.3 being defined for regular video. TG Tile Num is in the range [0..255], starting from 0. The upper 5bits are reserved for future expansion.
	11:0	**Frame Tile ID** Format: U12 All the tiles of a frame are labeled with a Frame Tile ID in a sequence raster order, starting from 0. The very first tile of a frame (top-left most corner) has Frame Tile ID = 0, and the last tile of a frame (bottom-right most corner)has the largest Frame Tile ID. So, the total number of tiles in a frame = (the largest Frame Tile ID + 1) = sum for all TG [largest Tile Num in a TG + 1]. Frame Tile ID is numbered from the 2 TG syntax elements TG_START and TG_END, or their default value when no present in the bitstream. Max number of tiles per frame is currently limited to 128 at the highest level 6.3 being defined for regular video. But for VR Large Scale Tile, max number of tiles per tile list is 512.Frame Tile ID is in the range [0..511], starting from 0.The upper 3bits are reserved for future expansion. Frame Tile ID numbering is consistent with the spec definition of tile ordering in a Tile Group and in a frame. Frame Tile ID does not get reset to 0 at Tile Group boundary (as the TG Tile Num does). Frame Tile ID numbering is not affected by dependency setting across tiles.
2	31:26	**Reserved** Access: RO Format: MBZ
	25:16	**Tile Row Position in SB Unit** Format: U10 Specify the row (y-) position of the current tile to be processed in a frame. The position is specified in SuperBlock unit. The SuperBlock unit is specified in the Sequence Header; it can be either 64x64 pixels or 128x128 pixels. For regular video, the decoded tile pixels are placed in the same tile location in the decoded output frame as the coded tile in the bitstream. But for VR Large Scale Tile, the decoded tile pixels can be placed in a different location predefined in the decoded pseudo output frame as the coded tile in the bitstream. This field is used for both regular video and VR Large Scale Tile. For VR Large Scale Tile, this field is programmed to be the coded tile position for MotionCompensation purpose, and the Output Decoded Tile Row Position field is then programmed to be the position in the decoded pseudo output frame for placing the decoded pixels of the tile, A Tile contains a 2D array of SB units. A Tile min. size is 1 SB unit. The Tile position is based on the top-left most corner SB unit of the Tile. The very first tile of a frame (top-left most corner) has the position [Tile Column Position in SB Unit , Tile Row Position in SB Unit] = [0, 0] The frame height is rounded up to an integer multiple of the Superblock unit. A frame height that is less than a SB unit (but must be >=8 pixels), is rounded up to 1 SB unit for

the purpose of defining a tile.
A frame height that is not divisible by tile height, the last tile row of the frame will have a smaller tile height, but still an integer multiple of SB unit. It does not affect the Tile Row Position in SB Unit of these partial Tiles.
Tile Row Position in SB unit is derived from the frame level syntax elements in tiling specifications (tile_info()).
Max Frame Height = 64K, hence the max number of SB unit= 1024, when the SB unit is 64x64 pixels, and the max Tile Row Position in SB unit can be 1023.
Intel supports Tile Row Position in SB unit only in the range of [0..255], for 16K Max Frame Height. starting from 0 at the top-left most corner of a frame.

Value	Name	Description
[0,255]	16K_Below	This allows support up to 16K picture

15:10 **Reserved**

Access:	RO
Format:	MBZ

9:0 **Tile Column Position in SB Unit**

Format:	U10

Specify the column (x-) position of the current tile to be processed in a frame. The position is specified in SuperBlock unit. The SuperBlock unit is specified in the Sequence Header; it can be either 64x64 pixels or 128x128 pixels.
For regular video, the decoded tile pixels are placed in the same tile location in the decoded output frame as the coded tile in the bitstream. But for VR Large Scale Tile, the decoded tile pixels can be placed in a different location predefined in the decoded pseudo output frame as the coded tile in the bitstream. This field is used for both regular video and VR Large Scale Tile.
For VR Large Scale Tile, this field is programmed to be the coded tile position for MotionCompensation purpose, and the Output Decoded Tile Column Position field is then programmed to be the position in the decoded pseudo output frame for placing the decoded pixels of the tile,
A Tile contains a 2D array of SB units. A Tile min. size is 1 SB unit. The Tile position is based on the top-left most corner SB unit of the Tile.
The very first tile of a frame (top-left most corner) has the position [Tile Column Position in SB Unit , Tile Row Position in SB Unit] = [0, 0]
The frame width is rounded up to an integer multiple of the Superblock unit.
A frame width that is less than a SB unit (but must be >= 8 pixels), is rounded up to 1 SB unit for the purpose of defining a tile.
A frame width that is not divisible by tile width, the last tile column of the frame will have a smaller tile width, but still an integer multiple of SB unit. It does not affect the Tile Column Position in SB Unit of these partial Tiles.
Tile Column Position in SB unit is derived from the frame level syntax elements in tiling specifications (tile_info()).
Max Frame Width= 64K, hence the max number of SB unit= 1024, when the SB unit is 64x64 pixels, and the max Column Row Position in SB unit can be 1023.
Intel supports Tile Column Position in SB unit only in the range of [0..255], for 16K Max Frame Width. starting from 0 at the top-left most corner of a frame.

AVP_TILE_CODING

		Value / **Name** / **Description**: [0,255] / 16K_Below / This allows support up to 16K picture.
3	31:26	**Reserved** Access: RO Format: MBZ
	25:16	**Tile Height in SuperBlock Unit Minus1** Format: U10 **Description**: Tile Size is measured in SuperBlock Unit. The SuperBlock unit is specified in the Sequence Header; it can be either 64x64 pixels or 128x128 pixels. When large-scale tile is ON, tile height must be 1 SB in size (i.e. can be 64x64 or 128x128, depending on the SB size flag). The minimum Tile Size is 1 SB unit x 1 SB unit The frame height is rounded up to an integer multiple of the Superblock unit. If a frame height is not divisible by the SuperBlock unit, the bottommost row of SBs of the frame is partial in size, but for the purpose of tile size definition, the partial SB is still counted as 1 unit. A frame height that is less than a SB unit, is rounded up to 1 SB unit for the purpose of defining a tile. A frame height that is not divisible by tile height, the last tile row of the frame will have a smaller tile height, but still an integer multiple of SB unit. Tile Height in SB unit is derived from the frame level syntax elements in tiling specifications (tile_info()). In AV1, there are two max tile size constraints : Max Tile Width <= 4096 pixels and Max Tile Area <= 4096 width x2304 height pixels. But there is no separate constraint for Max Tile Height. Intel set a limit for frame height to be 16K pixels. In AV1, the following restrictions apply: 1) Last SB (if partial in size)at frames bottommost edge must align to 8x8 block (partial SB) In AV1, the following additional restrictions apply: 1) In Scalability Mode, the minimum tile size is 2 width x1 height SBs. (Intel restriction) **Value** / **Name** / **Description**: [0,135] / 8704_and_Below / This supports upto 8704 (in pixels) for level 6.3.

	5:0	**Tile Width in SuperBlock Unit Minus1** Format: U6 **Description**: Tile Size is measured in SuperBlock Unit.The SuperBlock unit is specified in the Sequence

		Header; it can be either 64x64 pixels or 128x128 pixels. The minimum Tile Size is 1 SB unit x 1 SB unit The frame width is rounded up to an integer multiple of the Superblock unit. If a width height is not divisible by the SuperBlock unit, the rightmost column of SBs of the frame is partial in size, but for the purpose of tile size definition, the partial SB is still counted as 1 unit. A frame width that is less than a SB unit, is rounded up to 1 SB unit for the purpose of defining a tile. A frame width that is not divisible by tile width, the last tile column of the frame will have a smaller tile width, but still an integer multiple of SB unit. Tile Width in SB unit is derived from the frame level syntax elements in tiling specifications (tile_info()). In AV1, there are two max tile size constraints : Max Tile Width <= 4096 pixels and Max Tile Area <= 4096 width x2304 height pixels. But there is no separate constraint for Max Tile Height. When super-res is ON, these tile constraints are applied to the downscaled frame's tiles. So, Tile Width in SuperBlock Unit Minus1 is in the range of [0..63]. Tile Width = (Tile Width in SuperBlock Unit Minus1 + 1) SBs. In AV1, the following restrictions apply. 1) Last SB (if partial in size)at frames rightmost edge must align to 8x8 block (partial SB)
		In AV1, the following additional restrictions apply: 1) In Scalability Mode, the minimum tile size is 2 width x1 height SBs. (Intel restriction)
4	31	**Disable Frame Context Update Flag** Format: U1 **Description** Set to 0, the current tile being decoded is writing out its updated Frame Context to memory (surface buffer), at the end of its decoding. Set to 1, the current tile being decoded is not writing out its updated Frame Context to memory, for use in the next frame to be decoded. It is the frame level syntax element, disable_frame_end_update_cdf, or named as [! refresh_frame_context]. Default is 0. The arithmetic decoding of each tile of a frame is started with the same Frame Context (CDF Cumulative Probability Table Set for all AV1 Syntax Elements) provided by the Driver. This is from a read-only memory surface. After each arithmetic decoding of a Syntax Element from the bitstream,its corresponding CDF Table will be updated (if Disable CDF Update Flag = 0). As such, the frame context is changed after decoding each tile. When Backward Adaptation of the current frame context (CDF Cumulative Probability Table Set for all AV1 Syntax Elements) is enabled, only the largest tile in byte size (bitstream size) of the current frame being decoded will update the frame context for the decoding of the next frame. Driver will determine which tile in the current frame will need to write out its updated frame context to memory by setting Disable Frame Context Update Flag to 0. This is to a write-only memory surface. For all other tiles of the frame, Driver will set Disable Frame Context Update Flag to 1. If Driver knows, ahead of time, which tile has the largest bitstream size, then the frame context update can only be done once. If Driver does not know, ahead of time,which tile has the largest bitstream size, then the frame

		context update may be done more than once, and each time overwritten the previous one, until the largest tile has found. Note : Even when Error Resilient Mode is ON, this field can still be 0 or 1.
		When in Intel Scalability mode (multiple HW pipes), there are still be one read-only and one write-only frame context buffers allocated for decoding the current frame. And at anyone time, Driver will only enable one pipe to update/write out the frame context. Again it is possible that this update can be done more than once until the largest tile among all pipes has found.
	30	**Disable CDF Update Flag** Format: U1 Set to 1, the current tile being decoded is not updating the CDF table of each syntax element after parsing(multisymbol arithmetic decode) from the bitstream. Hence, the frame context is not being changed. And no need to write out the frame context at the end of decoding the frame. Set to 0, the current tile being decoded is updating the CDF table of each syntax element after parsing (multisymbol arithmetic decode) from the bitstream. Hence. the frame context is changed. If Disable Frame Context Update Flag = 0 for this tile, the new frame context is writing out to memory for subsequent frame decoding. It is the frame level syntax element, disable_cdf_update. Default is 0.
	29	**IsLastTileOfFrame Flag** Format: U1 Indicates if current tile being decoded is the last tile of a frame. Default is 0. The last tile is the bottom-right most corner region of a frame. This is intel specific frame level parameter.
	28	**IsEndTileOfTileGroup Flag** Format: U1 Indicates if current tile is the last tile of a Tile Group. Default is 0. 0 - is not the end tile of a tile group 1 - is the end tile of a tile group. It is derived as : isEndTileOfTileGroup = (Frame Tile ID = = TG_END syntax element) A Tile Group can end at any tile in a tile row (e.g. the first tile of a tile row, the last tile of a tile row, or a tile anywhere in the middle of a tile row). The End tile of a Tile Group may not be in the same tile row as the Start tile of the same Tile Group, but must come after in raster order. This is intel specific frame level parameter.
	27	**IsStartTileOfTileGroup Flag** Format: U1 Indicates if current tile is the first tile of a Tile Group. Default is 0. 0 - is not the start tile of a tile group 1 - is the start tile of a tile group. It is derived as : isStartTileOfTileGroup = (Frame Tile ID = = TG_START syntax element) A Tile Group can start at any tile in a tile row (e.g. the first tile of a tile row, the last tile of a tile

		row, or a tile anywhere in the middle of a tile row). The End tile of a Tile Group may not be in the same tile row as the Start tile of the same Tile Group. This is intel specific frame level parameter.
	26	**IsLastTileOfRow Flag** Format: U1 Indicates if the current tile is the last tile of the current tile row. Default is 0. 0 - is not the last tile of a tile row 1 - is the last tile of a tile row. It is derived from Frame Tile ID and Num of Tile Columns Minus1. It is the tile at the right frame boundary. The bottom-right most tile of a frame is having both IsLastTileOfRow and IsLastTileOfColumn set to 1. This is intel specific frame level parameter.
	25	**IsLastTileOfColumn Flag** Format: U1 Indicates if the current tile is the last tile of the current tile column. Default is 0. 0 - is not the last tile of a tile column 1 - is the last tile of a tile column. It is derived from Frame Tile ID, Num of Tile Columns Minus1and Num of Tile Rows Minus1. is the tile at the bottom frame boundary. The bottom-right most tile of a frame is having both IsLastTileOfRow and IsLastTileOfColumn set to 1. This is intel specific frame level parameter.
	24	**Reserved** Access: RO Format: MBZ
	23	**Reserved** Access: RO Format: MBZ
	22:4	**Reserved** Access: RO Format: MBZ
	3:0	**Reserved** Access: RO Format: MBZ
5	31:22	**Num of Tile Rows Minus1 in a Frame** Format: U10

Specify the total number of Tile Rows in a frame.
TileRows =Num of Tile Rows Minus1 in a Frame + 1.
Max Frame Height is 64K, the smallest tile size is 1SB unit, hence max number of tile rows in a frame can be 1024.
Valid Num of Tile Rows Minus1 in a Frame is in the range of [0..63] only. The max tile number in a frame is governed by the Level definition for a compliant bitstream.
For regular video, highest Level defined is 6.3 (max. 8K video), which specifies max total 128 tiles in a frame and max number of tile columns is 16. The corresponding tile configuration is flexible, it can be 16x8, 8x16, 16x4, 4x16, 8x8, etc. There is no constraints on max number of tile rows.
For VR large scale tile application, the tile configuration can be max total 64x64=4K tiles in a pseudo output frame and an anchor frame. But the tile list can max. contain 512 tiles at a time.
This is the same as the variable tile_rows (minus1)defined in the reference C model.
Num of Tile Rows in a frame is derived from the frame level syntax elements in tiling specifications (tile_info()).

21:12 **Num of Tile Columns Minus1 in a Frame**

Format:	U10

Description

Specify the total number of Tile Columns in a frame.
TileColumns=Num of Tile Columns Minus1 in a Frame + 1.
Max Frame Width is 64K, the smallest tile size is 1SB unit, hence max number of tile columns in a frame can be 1024.
Valid Num of Tile Columns Minus1 in a Frame is in the range of [0..63] only. The max tile number in a frame is governed by the Level definition for a compliant bitstream.
For regular video, highest Level defined is 6.3 (max. 8K video), which specifies max total 128 tiles in a frame and max number of tile columns is 16. The corresponding tile configuration is flexible, it can be 16x8, 8x16, 16x4, 4x16, 8x8, etc. There is no constraints on max number of tile rows.
For VR large scale tile application, the tile configuration can be max total 64x64=4K tiles in a pseudo output frame and an anchor frame. But the tile list can max. contain 512 tiles at a time.
This is the same as the variable tile_cols (minus1) defined in the reference C model.
Num of Tile Columns in a frame is derived from the frame level syntax elements in tiling specifications (tile_info()).

In Intel Scalability Mode (multiple HW pipes), execution across multiple pipes is done in tile column fashion. When the number of tile columns in a frame > the number of HW pipes, the tile columns are cycled through the pipes in multiple phases as described below:
Tile Col0/Row0 | Tile Col1/Row0 | Tile Col2/Row0
Tile Col0/Row1 | Tile Col1/Row1 | Tile Col2/Row1
Tile Col0/Row2 | Tile Col1/Row2 | Tile Col2/Row2
Assume there is only 2 HW pipes (Pipe0 and Pipe1)
Phase 0:
Pipe0 :Tile Col0/Row0 ; Pipe1 : Tile Col1/Row0
Phase 1:

		Pipe0 :Tile Col2/Row0 Phase 2: Pipe0 :Tile Col0/Row1 ; Pipe1 : Tile Col1/Row1 Phase 3: Pipe0 :Tile Col2/Row1 Phase 4: Pipe0 :Tile Col0/Row2 ; Pipe1 : Tile Col1/Row2 Phase 5: Pipe0 :Tile Col2/Row2.
	11:8	**Reserved MBZ** Format: MBZ
	7:0	**Number of Active BE Pipes** Indicates the number of active, consecutive positioned Scalable VDBOXs to be used for the current frame decoding or encoding. BE Pipe partitioning, SW must guarantee the minimum width is at least two full SBs for each tiles This field in general should be smaller or equal to Num of Tile columns in a Frame. This field is ignored by HW This field is not used by HW

Bit Field Extract

bfe - Bit Field Extract

Source:	Eulsa
Length Bias:	4
Predication:	true
Conditional Modifier:	false
Saturation:	false
Source Modifier:	false

Component-wise extract a bit field from src2 using the bit field width from src0 and the bit field offset from src1. Store the extracted bit field value in the low bits of dst and sign extend (if D type) or zero extend (if UD type). The width and offset values are from the low five bits of src0 and src1 respectively, or src0 & 0x1f and src1 & 0x1f. If width is zero, the result is zero. If offset + width > 32 then the extracted bit field is bits offset to 31 of src2, extracting only 32 - offset bits, less than width as the bit field cannot extend past the MSB of the source value. Otherwise extract width bits extending from bit positions offset to offset + width - 1.

Format:

```
[(pred)] bfe (exec_size) dst src0 src1 src2
```

Restriction

No accumulator access, implicit or explicit.

All three-source instructions have certain restrictions, described in Instruction Formats.

Syntax

```
[(pred)] bfe (exec_size) reg reg reg reg
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.chan[n] ) {
         UD width = src0.chan[n][4:0];
         UD offset = src1.chan[n][4:0];
         if ( width == 0 ) {
             dst.chan[n] = 0x00000000;
         } else if ( (width + offset) < 32 ) {
             dst.chan[n] = src2.chan[n] « (32 - width - offset);
             if (src2 is signed) {
                 dst.chan[n] = dst.chan[n] » (32 - width); // pad sign bit of dst.chan
             } else {
                 dst.chan[n] = dst.chan[n] » (32 - width); // pad 0
             }
         } else {
             if ( src2 is signed ) {
                 dst.chan[n] = src2.chan[n] » offset; // pad sign bit
             } else {
                 dst.chan[n] = src2.chan[n] » offset; // pad 0
             }
         }
     }
 }
```

Per channel write enable used for final write enable generation. 1 / NoMask / NoMask.Skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.
	30	**Reserved**
	29	**CmptCtrl** Format: MBZ

Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction **[Default]**	No compaction. 128-bit native instruction supporting all instruction options.
1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

28 **PredInv**

This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl.
1	Negative	Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.

27:24 **PredCtrl**

Format:	PredCtrl

This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register.

23 **FlagRegNum[0]**

This field specifies bit[0] of the register number for a flag register operand.

22 **FlagSubRegNum**

This field specifies the sub-register number for a flag register operand. There are two sub-registers in the flag register. Each sub-register contains 16 flag bits. The selected flag sub-register is the source for predication if predication is enabled for the instruction. It is the destination to store conditional flag bits if conditional modifier is enabled for the instruction. The same flag sub-register can be both the predication source and conditional destination, if both predication and conditional modifier are enabled.

21:19 **ChanOff**

Format:	ChanOff

This field provides offset information for ARF selection. This can be thought of as a starting channel offset for the execution mask and other ARF registers implicitly accessed.

bfe - Bit Field Extract		
	18:16	**ExecSize** Format: **ExecSize** This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.
	15:0	**Header** Format: **Header**

Bit Field Insert 1

bfi1 - Bit Field Insert 1

Source:	Eulsa
Length Bias:	4
Predication:	true
Conditional Modifier:	false
Saturation:	false
Source Modifier:	false

The bfi1 instruction is the first instruction in a two-instruction macro for bfi (Bit Field Insert). The bfi1 instruction component-wise generates mask with control from src0 and src1 and stores the results in dst. The mask is used in the bfi2 instruction to generate the final result of bfi. Create a bit mask corresponding to the bit field width and offset in src0 and src1. Store the bit mask in dst. The mask has all bits in the bit field set to 1 and all other bits as 0. The width and offset values are from the low five bits of src0 and src1 respectively, or src0 & 0x1f and src1 & 0x1f. If width is zero, the result is zero. The bfi macro has four source operands: src0 - bit field width in low five bits, src1 - bit field offset/starting bit position in low five bits, src2 - bit field value to insert, using only the number of least significant bits given by width in src0, and src3 - overall value into which the bit field is inserted, providing all bits other than the inserted bits for the result value. bfi dst src0 src1 src2 src3 // Translates to these two instructions: bfi1 dst src0 src1 bfi2 dst dst src2 src3

Format:

```
[(pred)] bfi1 (exec_size) dst src0 src1
```

Programming Notes

No accumulator access, implicit or explicit.

Syntax

```
[(pred)] bfi1 (exec_size) reg reg reg
 [(pred)] bfi1 (exec_size) reg reg imm32
```

Pseudocode

```
Evaluate(WrEn);
     for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.chan[n] ) {
          UD width = src0.chan[n][4:0];
          UD offset = src1.chan[n][4:0];
          dst = ((1 « width) - 1) « offset;
     }
 }

Mask Control (formerly Write Enable Control). This field determines if the per channel write enables are used to generate the final write enable. This field should be normally "0".

Value	Name	Description
0	Normal **[Default]**	Normal. Per channel write enable used for final write enable generation.
1	NoMask	NoMask.Skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.

30 Reserved

29 CmptCtrl

Format:	MBZ

Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction **[Default]**	No compaction. 128-bit native instruction supporting all instruction options.
1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

28 PredInv

This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits

bfi1 - Bit Field Insert 1

generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl.
1	Negative	Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.

27:24 **PredCtrl**

Format:	PredCtrl

This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register.

23 **FlagRegNum[0]**

This field specifies bit[0] of the register number for a flag register operand.

22 **FlagSubRegNum**

This field specifies the sub-register number for a flag register operand. There are two sub-registers in the flag register. Each sub-register contains 16 flag bits. The selected flag sub-register is the source for predication if predication is enabled for the instruction. It is the destination to store conditional flag bits if conditional modifier is enabled for the instruction. The same flag sub-register can be both the predication source and conditional destination, if both predication and conditional modifier are enabled.

21:19 **ChanOff**

Format:	ChanOff

This field provides offset information for ARF selection. The can be thought of as a starting channel offset for the execution mask and other ARF registers implicitly accessed.

18:16 **ExecSize**

Format:	ExecSize

This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.

15:0 **Header**

Format:	Header

Bit Field Insert 2

bfi2 - Bit Field Insert 2

Source:	Eulsa
Length Bias:	4
Predication:	true
Conditional Modifier:	false
Saturation:	false
Source Modifier:	false

The bfi2 instruction is the second instruction in a two-instruction macro for bfi (Bit Field Insert). The bfi2 instruction component-wise performs the bitfield insert operation on src1 and src2 based on the mask in src0. Use the mask in src0 to take a bit field value from the low bits of src1 and combine it with the value from src2 (so src2 provides all bits other than those masked out and replaced by the bit field value). Store the result in dst. The bfi macro has four source operands: src0 - bit field width in low five bits, src1 - bit field offset/starting bit position in low five bits, src2 - bit field value to insert, using only the number of least significant bits given by width in src0, and src3 - overall value into which the bit field is inserted, providing all bits other than the inserted bits for the result value. bfi dst src0 src1 src2 src3 // Translates to these two instructions: bfi1 dst src0 src1 bfi2 dst dst src2 src3

Format:

```
[(pred)] bfi2 (exec_size) dst src0 src1 src2
```

Restriction

No accumulator access, implicit or explicit.

All three-source instructions have certain restrictions, described in Instruction Formats.

Syntax

```
[(pred)] bfi2 (exec_size) reg reg reg reg
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.chan[n] ) {
         UD offset = LZD(reverse(src0.chan[n]))-1;
         // offset is the number of LSB zero bits below the bit mask which has all 1s.
         // width (implied by the logic) is the number of 1 bits in the mask value, which
should be all 1s.
         dst.chan[n] = ((src1.chan[n] « offset) & src0.chan[n]) | (src2.chan[n] & !
src0.chan[n]);
     }
 }
```

Branch Converging

brc - Branch Converging

Source:	EuIsa
Length Bias:	4
Predication:	true
Conditional Modifier:	false
Saturation:	false
Source Modifier:	false

The brc instruction redirects the execution forward or backward to the instruction pointed by (current IP + offset). The jump will occur if all channels are branched away. UIP should reference the instruction where all channels are expected to come together. JIP should reference the end of the innermost conditional block.

In instruction binary, JIP and UIP use locations src1 and src0 respectively when immediate and location src0 when reg64, where reg64 is accessed as paired DWord (regioning being <2;2,1>). dst must be IP. When the offsets are immediate, src0 regfile must be immediate.

Format:

```
[(pred)] brc (exec_size) JIP UIP
```

Restriction

A brc instruction cannot use the Switch instruction option.

Syntax

```
[(pred)] brc (exec_size) imm32 imm32
 [(pred)] brc (exec_size) reg64
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < 32; n++ ) {
    if ( WrEn[n] ) {
       PcIP[n] = IP + UIP;
    } else {
       PcIP[n] = IP + 1;
    }
 }
 if ( all PcIP != IP + 1 ) {  // for all channels
    Jump(IP + JIP);
 }
```

Format:	MBZ

Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction **[Default]**	No compaction. 128-bit native instruction supporting all instruction options.
1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

28 **PredInv**

This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl.
1	Negative	Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.

27:24 **PredCtrl**

Format:	PredCtrl

This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register.

23 **FlagRegNum[0]**

This field specifies bit[0] of the register number for a flag register operand.

22 **FlagSubRegNum**

This field specifies the sub-register number for a flag register operand. There are two sub-registers in the flag register. Each sub-register contains 16 flag bits. The selected flag sub-register is the source for predication if predication is enabled for the instruction. It is the destination to store conditional flag bits if conditional modifier is enabled for the instruction. The same flag sub-register can be both the predication source and conditional destination, if

brd - Branch Diverging

		both predication and conditional modifier are enabled.
	21:19	**ChanOff** Format: **ChanOff** This field provides offset information for ARF selection. The can be thought of as a starting channel offset for the execution mask and other ARF registers implicitly accessed.
	18:16	**ExecSize** Format: **ExecSize** This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.
	15:0	**Header** Format: **Header**

Break

break - Break

Source:	EuIsa
Length Bias:	4
Predication:	true
Conditional Modifier:	false
Saturation:	false
Source Modifier:	false

The break instruction is used to early-out from the inner most loop, or early out from the inner most switch block. When used in a loop, upon execution, the break instruction terminates the loop for all execution channels enabled. If all the enabled channels hit the break instruction, jump to the instruction referenced by JIP. JIP should be the offset to the end of the inner most conditional or loop block, UIP should be the offset to the while instruction of the loop block. If SPF is ON, the UIP must be used to update IP; JIP is not used in this case

The following table describes the two 32-bit instruction pointer offsets. Both the JIP and UIP are signed 32-bit numbers, added to IP pre-increment. In instruction binary, JIP and UIP are at locations src0 and src1 and must be of type DW (signed DWord integer). When the offsets are immediate, src0 regfile must be immediate.

Format:

```
[(pred)] break (exec_size) JIP UIP
```

Syntax

```
[(pred)] break (exec_size) imm32 imm32
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.channel[n] ) {
         PcIP[n] = IP + UIP;
     } else {
         PcIP[n] = IP + 1;
     }
 }
 if ( PcIP != (IP + 1) ) { // all channels
     Jump(IP + JIP);
 }
```

break - Break

33 BranchCtrl

This field is used by *goto*, *if*, and *else* instructions to control branching. See the goto instruction description for more information about BranchCtrl.

32 AtomicCtrl

Format:	AtomicCtrl

31 MaskCtrl

Mask Control (formerly Write Enable Control). This field determines if the per channel write enables are used to generate the final write enable. This field should be normally "0".

Value	Name	Description
0	Normal **[Default]**	Normal. Per channel write enable used for final write enable generation.
1	NoMask	NoMask.Skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.

30 Reserved

29 CmptCtrl

Format:	MBZ

Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction **[Default]**	No compaction. 128-bit native instruction supporting all instruction options.
1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

28 PredInv

This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl.
1	Negative	Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.

27:24 PredCtrl

Format:	PredCtrl

This field, together with PredInv, enables and controls the generation of the predication mask

Call

call - Call

Source:	EuIsa
Length Bias:	4
Predication:	true
Conditional Modifier:	false
Saturation:	false
Source Modifier:	false

The call instruction jumps to a subroutine. It can be predicated or non-predicated. If non-predicated, all enabled channels jump to the subroutine. If predicated, only the channels enabled by PMask jump to the subroutine; the rest of the channels move to the next instruction after the call instruction. If none of the channels jump into the subroutine, the call instruction is treated as a nop. In case of a jump, the call instruction stores the return IP onto the first DWord of the destination register and stores the CallMask in the second DWord of the destination register. When SPF is on, the predication control must be scalar.

The following section describes JIP, the jump offset.
JIP can be an immediate or register value. When a jump occurs, this value is added to IP pre-increment. In instruction binary, JIP is at location src1 and src0 must be null. The GRF register must be put (for example, by the assembler) at dst location.
Format: [(pred)] call (exec_size) dst JIP

Format:

```
[(pred)] call (exec_size) dst JIP
```

Restriction

The call instruction must have DWord source and destination type, and the destination must be QWord aligned.

A call instruction must target an instruction with Switch set; in addition, the instruction following the call must also have Switch set.

When EU Fusion is enabled JIP of both EU's must be same.

Syntax

```
[(pred)] call (exec_size) reg imm32 [(pred)] call (exec_size) reg reg32
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if (WrEn.chan[n] ) {
         PcIP[n] = IP + JIP;
         CallMask[n] = 1;
     } else {
         PcIP[n] = IP + 1;
         CallMask[n] = 0;
     }
 }
```

call - Call

```
if ( PcIP[n] != (IP + 1) ) {  // any channel jumped
    dst.chan[0] = IP + 1;
    dst.chan[1] = CallMask;
    Jump(IP + JIP);
}
```

33 **BranchCtrl**

This field is used by *goto*, *if*, and *else* instructions to control branching. See the **goto** instruction description for more information about BranchCtrl.

32 **AtomicCtrl**

Format:	**AtomicCtrl**

31 **MaskCtrl**

Mask Control (formerly Write Enable Control). This field determines if the per channel write enables are used to generate the final write enable. This field should be normally "0".

Value	Name	Description
0	Normal **[Default]**	Normal. Per channel write enable used for final write enable generation.
1	NoMask	NoMask.Skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.

30 **Reserved**

29 **CmptCtrl**

Format:	MBZ

Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction **[Default]**	No compaction. 128-bit native instruction supporting all instruction options.
1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

28 **PredInv**

This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl.
1	Negative	Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.

call - Call

	27:24	**PredCtrl** Format: **PredCtrl** This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register.
	23	**FlagRegNum[0]** This field specifies bit[0] of the register number for a flag register operand.
	22	**FlagSubRegNum** This field specifies the sub-register number for a flag register operand. There are two sub-registers in the flag register. Each sub-register contains 16 flag bits. The selected flag sub-register is the source for predication if predication is enabled for the instruction. It is the destination to store conditional flag bits if conditional modifier is enabled for the instruction. 	18:16	**ExecSize** Format: **ExecSize** This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.
	15:0	**Header** Format: **Header**

Call Absolute

calla - Call Absolute

Source:	EuIsa
Length Bias:	4
Predication:	true
Conditional Modifier:	false
Saturation:	false
Source Modifier:	false

The calla instruction jumps to a subroutine. It can be predicated or non-predicated. If non-predicated, all enabled channels jump to the subroutine. If predicated, only the channels enabled by PMask jump to the subroutine; the rest of the channels move to the next instruction after the calla instruction. If none of the channels jump into the subroutine, the calla instruction is treated as a nop. In case of a jump, the call instruction stores the return IP onto the first DWord of the destination register and stores the CallMask in the second DWord of the destination register. If SPF is ON, none of the PcIP are updated. When SPF is on, the predication control must be scalar. The difference between calla and call is that calla uses JIP as the IP value rather than adding it to the IP value.

Format:

```
[(pred)] calla (exec_size) dst JIP
```

Restriction

The calla instruction must have DWord source and destination type, and the destination must be QWord-aligned.

When EU Fusion is enabled JIP of both EU's must be same.

Syntax

```
[(pred)] calla (exec_size) reg imm32
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.channel[n] ) {
         PcIP[n] = JIP;
         CallMask[n] = 1;
     } else {
         PcIP[n] = IP + 1;
         CallMask[n] = 0;
     }
 }
 if ( PcIP[n] != (IP + 1) ) {  // any channel jumped
     dst.chan[0] = IP + 1;
     dst.chan[1] = CallMask;
     Jump(JIP);
 }

Compare

cmp - Compare

Source:	EuIsa
Length Bias:	4
Predication:	true
Conditional Modifier:	true
Saturation:	false
Source Modifier:	true

The cmp instruction performs component-wise comparison of src0 and src1 and stores the results in the selected flag register and in dst. It takes component-wise subtraction of src0 and src1, evaluating the conditional code (excluding NS signal) based on the conditional modifier, and storing the conditional bits in bit-packed form in the destination flag register and all bits of dst channels. If the dst is not null, for the enabled channels, then all bits of the destination channel will contain the flag value for the channel. When the instruction operates on packed word format, one general register may store up to 16 such comparison results. In DWord format, one general register may store up to 8 results. A conditional modifier must be specified; the conditional modifier field cannot be 0000b. The comparison does not use the NS (NaN source) signals, as described in the Creating Conditional Flags section. Accordingly the conditional modifier should not be .u (unordered). For each enabled channel 0b or 1b is assigned to the appropriate flag bit and 0/all zeros or all ones (e.g, byte 0xFF, word 0xFFFF, DWord 0xFFFFFFFF) is assigned to dst. When any source type is floating-point, the cmp instruction obeys the rules described in the tables in the Floating Point Modes section of the Data Types chapter.

Format:

```
[(pred)] cmp[.cmod] (exec_size) dst src0 src1
```

Syntax

```
[(pred)] cmp[.cmod] (exec_size) reg reg reg
 [(pred)] cmp[.cmod] (exec_size) reg reg imm32
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.chan[n] ) {
         results[n] = src0.chan[n] - src1.chan[n];
         bitMask[n] = Condition(results[n]); // details in Assigning Conditional Flags
dst.chan[n] = bitMask[n]; // All bits for dst channel
         flag#.bit[n]= bitMask[n];
     }
 }
```

31 **MaskCtrl**

Mask Control (formerly Write Enable Control). This field determines if the per channel write enables are used to generate the final write enable. This field should be normally "0".

Value	Name	Description
0	Normal **[Default]**	Normal. Per channel write enable used for final write enable generation.
1	NoMask	NoMask.Skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.

30 **Reserved**

29 **CmptCtrl**

Format:	MBZ

Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction **[Default]**	No compaction. 128-bit native instruction supporting all instruction options.

1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

28 **PredInv**

This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl.
1	Negative	Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.

27:24 **PredCtrl**

Format:	PredCtrl

This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register.

23 **FlagRegNum[0]**

This field specifies bit[0] of the register number for a flag register operand.

22 **FlagSubRegNum**

This field specifies the sub-register number for a flag register operand. There are two sub-registers in the flag register. Each sub-register contains 16 flag bits. The selected flag sub-register is the source for predication if predication is enabled for the instruction. It is the destination to store conditional flag bits if conditional modifier is enabled for the instruction. The same flag sub-register can be both the predication source and conditional destination, if both predication and conditional modifier are enabled.

21:19 **ChanOff**

Format:	ChanOff

This field provides offset information for ARF selection. The can be thought of as a starting channel offset for the execution mask and other ARF registers implicitly accessed.

18:16 **ExecSize**

Format:	ExecSize

This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.

15:0 **Header**

Format:	Header

Compare NaN

cmpn - Compare NaN

Source:	EuIsa
Length Bias:	4
Predication:	true
Conditional Modifier:	true
Saturation:	false
Source Modifier:	true

The cmpn instruction performs component-wise special-NaN comparison of src0 and src1 and stores the results in the selected flag register and in dst. It takes component-wise subtraction of src0 and src1, evaluating the conditional signals including NS based on the conditional modifier, and storing the conditional flag bits in bit-packed form in the destination flag register and all bits of dst channels. If the dst is not null, for the enabled channels, then all bits of the destination channel will contain the flag value for the channel. When the instruction operates on packed word format, one general register may store up to 16 such comparison results. In DWord format, one general register may store up to 8 results. A conditional modifier must be specified; the conditional modifier field cannot be 0000b. More information about the conditional signals used is in the Creating Conditional Flags section. For each enabled channel 0b or 1b is assigned to the appropriate flag bit and 0/all zeros or all ones (e.g, byte 0xFF, word 0xFFFF, DWord 0xFFFFFFFF) is assigned to dst. Min/Max instructions use cmpn to select the destination from the input sources (see the Min Max of Floating Point Numbers section for details).

Format:

```
[(pred)] cmpn[.cmod] (exec_size) dst src0 src1
```

Restriction

.l and .ge are the only two conditional modifiers are supported for this instruction.

Syntax

```
[(pred)] cmpn[.cmod] (exec_size) reg reg reg
 [(pred)] cmpn[.cmod] (exec_size) reg reg imm32
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     if ( WrEn.chan[n] ) {
         results[n] = src0.chan[n] - src1.chan[n];
         bitMask[n] = ConditionNaN(results[n]); // details in Assigning Conditional Flags
dst.chan[n][0] = bitMask[n]; // All bits for dst channel
         flag#.bit[n] = bitMask[n];
     }
 }
```

This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.

cmpn - Compare NaN		
	15:0	**Header** Format: **Header**

Conditional Select

csel - Conditional Select

Source:	EuIsa
Length Bias:	4
Predication:	false
Conditional Modifier:	true
Saturation:	true
Source Modifier:	true

The csel instruction selectively moves components in src0 or src1 to the dst based on the result of the compare of src2 with zero. If the channel condition is true, data in src0 is moved into dst. Otherwise, data in src1 is moved into dst. The csel instruction provides the function of a cmp followed by sel. The instruction must not be used if cmpn is required. The instruction does not update the flag register.
The comparison follows the same rule as cmp instruction for that data type.

When Access Mode is Align1, accumulator may be used as source or destination.

Format:

```
csel (exec_size) dst src0 src1 src2
```

Syntax

```
csel[.cmod] (exec_size) reg reg reg reg
```

Pseudocode

```
Evaluate(WrEn);
 for ( n = 0; n < exec_size; n++ ) {
     bitMask[n] = 0;
     if ( EMask.chan[n] ) {
         result[n] = src2.chan[n] - 0;
         bitMask[n] = Condition(result[n]);
         if (bitMask[n] = 1) {
             dst.chan[n] = src0.chan[n];
         } else {
             dst.chan[n] = src1.chan[n];
         }
     }
 }
```
